On motion of Senator Dill of Washington the Senate on Tuesday demanded a conference upon the "equal distribution" amendment that was attached by the House to the Senate bill extending the life of the Federal Radio Commission for one year. Although sympathetic with the purpose of the House to distribute radio stations equally upon the basis of population, Senator Dill said that the language of the amendment made it unworkable and impracticable. The conference was set for Friday, March 16. Senator Dill said that although the commission's regulatory powers would technically expire at midnight of March 15, he believed the commissioners would continue to serve until the conference reached an agreement. Nominally Secretary Hoover will again be in charge.

## Philadelphia Electric Will Speed 1928 Program

The Philadelphia Electric Company, through its president, William H. Taylor, has just announced some of the details of its twelve-million-dollar building, construction and equipment plans for 1928, following a statement by Arthur W. Thompson, president of the United Gas Improvement Company, that a construction program of $20,000,000 will be pushed by the U.G.I. and its allied companies in an effort to relieve non-employment. Mr. Taylor said:

"Our program involves such major items as the installation of huge condensers and transformers in the Plymouth Meeting substation near Norristown and the Westmoreland substation in Philadelphia, erection of an 80,000-kva. tie line between Plymouth Meeting and the generating station at Norristown of the Philadelphia-Suburban Counties Gas & Electric Company, the new Lamokin substation which will be built in Chester to supply power for the electrification of the Pennsylvania Railroad between Philadelphia and Wilmington and other important additions. The Lamokin substation will contain three 21,000-kva., single-phase, 25-cycle motor-generator sets—the largest of their kind which have been built."

## Nine Hundred at Tulsa

*Oklahoma Utilities Association Hears Industry Leaders in Its General and Group Sessions—Growth of Electric Generating Stations in State*

FORMER attendance records were shattered at the tenth annual convention of the Oklahoma Utilities Association, held at the Mayo Hotel, Tulsa, on March 13, 14 and 15. Approximately nine hundred had registered at the end of the second day. General sessions were held in the forenoons, and the various groups—electric light and power, gas, electric railway, telephone, public relations, manufacturers and suppliers, public relations and women's committee—held afternoon sessions.

E. F. McKay, manager of the association, in his annual report, revealing substantial association growth, said that the total capacity of electric generating stations in the state is now 360,000 hp. At the Wednesday morning session J. F. Owens, Oklahoma City, chairman Public Relations National Section, N.E.L.A., especially stressed the work of the committee on co-operation with educational institutions. About six hundred persons attended the banquet, where the principal speaker was Representative Charles A. Eaton of New Jersey. The election of officers was scheduled for Thursday afternoon.

## Purchases and Mergers

*Buffalo, Niagara & Eastern Subsidiaries to Be Merged—Transfers of Control of Minor Private and Public Plants in Many States Reported*

MERGER into the Buffalo, Niagara & Eastern Power Corporation of its subsidiaries, to take place in the near future, following a stock issue, was announced at Buffalo on March 13. The merger is to embrace the Buffalo General Electric Company, Niagara Electric Service Corporation, Niagara, Lockport & Ontario Power Company, Niagara Falls Power Company and the Tonawanda Power Company.

Citizens of Kinston, N. C., will determine the fate of Kinston's municipal electric light plant at a special election July 3. The Carolina Gas & Electric Company, with headquarters at Kinston, as already reported, offers to pay $1,271,000 for the power house, besides making the city a present of a "white way," and the Aldermen accepted this bid subject to ratification. Livingston & Gregory, of New York and Salisbury, N. C., have resubmitted their offer for the property—$1,357,000, including a good-faith check for $100,000 deposited with the bid.

The Appalachian Electric Power Company has bought the Montvale-Thaxton Transmission Company's line between the Virginia towns indicated, previously served by the Bedford City municipal plant.

The South Georgia Power Company has taken over and grouped under one management the municipal plants at Richland, Buena Vista and Lumpkin, Ga., all of these towns now being on a 110-volt transmission line reaching Americus and Columbus.

John F. Brewer of Mountain View, Ark., has sold a 99-year franchise for supplying power and light in that place to the Arkansas Power & Light Company.

The Bristol (Tenn.) Gas & Electric Company has purchased the franchise of the Boon Creek Electric Company at Mountain City, Tenn.

Mendenhall (Miss.) taxpayers have approved the sale of the municipal electric system to M. L. Culley for $10,000 cash.

Upon rehearing of petitions, the Illinois Commerce Commission has authorized the Illinois Power & Light Corporation to purchase the Arenzville Light & Power Company for $74,000 and the Prather & Hill Electric Light and the Elkhart Electric Light companies for $40,000. Petition for permission to purchase the municipal electric system in Dahlgren, Ill., has been filed with the commission by the Central Public Service Company.

The Interstate Power & Light Corporation is reported to have acquired the lighting plants in Mansfield, Seymour, Ava, Norwood and Mountain Grove, Mo., which will be operated as the Missouri Electric Power Company.

The Maryville Electric Light & Power Company has applied to the Missouri Public Service Commission for authority to buy the distribution plant of the Union Star (Mo.) Electric Company for $12,500. The commission has authorized the Fairfax Light, Heat & Power Company to sell its electrical distribution plant to the Tarkio Electric & Water Company for $25,000.

The Central Power Company has purchased the distribution systems in the town of Brock, as previously noted, and also in Dunbar and Farwell, Neb. The lines were formerly owned by these municipalities. All of the towns have been served wholesale by the Central Power Company.

Purchase of the municipal electric and water systems at Thomas, Okla., by the Southwestern Light & Power Company was authorized by the voters Feb. 14.

These purchases are reported from North Central states: The Otter Tail Power Company has bought the Makoti (N. D.) village lighting systems and plants at Binford, Eckelson, Dwight and Parshall, N. D.; Eastern Minnesota Power Company, the Pappenfus power system at Oak Park, Minn.; Dakota Power Company, the Custer (S. D.) Light & Power Company; Northern States Power Company, the lighting system at Ruthton, Minn.; Interstate Power Company, the Clearbrook (Minn.) plant, and Montana-Dakota Power Company, the plants at Larson, Beach, Sentinel and Butte, N. D.

The Southern Colorado Power Company, through W. N. Clark and George W. Milliken, has offered the city of Lamar, Colo., $350,000 cash for its power plant if the city will grant it a 25-year franchise.

The South American Power Company, a subsidiary of American & Foreign Power Company, has taken control of the South Brazilian Railways Company from the International Light & Power Company. The South Brazilian Railways Company owns and operates the electric power and light and street-railway systems in Curityba, in south Brazil.

---

# St. Louis Institute Meeting Well Staged

### Large Attendance and Lively Interest Mark Regional Convention—System and Machine Stability, Automatic Switching, Lightning and Television Among Topics

A CRITICAL discussion that followed the presentations of two related papers—one on the influence of excitation systems on short circuits and maximum power and the other on a new development in voltage regulators—marked the high point in the regional meeting of the American Institute of Electrical Engineers held at St. Louis on March 7, 8 and 9. This convention of the Southwestern District of the Institute was successful in all ways, having to its credit an attendance of more than 400, a program of practical and interesting papers and a smoothness of organization and procedure that reflected great credit on the local St. Louis committees. A branch conference attended by students from many of the Southwestern colleges opened the three-day meeting. This was followed by a joint luncheon with the St. Louis Electrical Board of Trade, at which Bancroft Gherardi, president of the parent body, spoke on transatlantic telephony.

The first technical session was presided over by A. E. Bettis, vice-president of the Southwestern District. The development of an empirical method for determining leakage and fringing fluxes in an electromagnetic system was reported by W. L. Upson and E. L. Furth. Hans Weichsel did much to destroy the illusion that splitting the resistance rings on a squirrel-cage rotor will always result in an increase of motor starting torque. On the contrary, it will, according to the tests made by Mr. Weichsel, so increase leakage as actually to decrease that torque. The development of the various types of drives for tandem rolling mills was covered by A. F. Kenyon. Methods of calculation of power requirements were set forth.

The very worth-while results that have been obtained from consistent checking and testing of purchased material by the Kansas City Power & Light Company were enumerated at the second technical session by D. D. Clark and G. E. Meredith, whose paper was entitled "The Public Utility Laboratory and Its Relation to Service." Following this came a description, by Stanley Stokes and Leslie V. Nelson, of the metering equipment that is used to establish billing demands on the output of Cahokia station, where six sub-totalizers integrate the demands on six lines. The coincident registrations of these six are combined on the master totalizer.

#### EXCITEMENT OVER EXCITATION

Insistence by Chairman L. F. Woolston kept impatient discussers in check after R. H. Park had read R. E. Doherty's paper on excitation systems until additional material for argument had accrued from the paper on voltage regulators by R. M. Carothers and C. A. Nickle. The theme of the first of the two papers was that in the performance of alternators both static stability—that is, stability under or more or less gradual accretions of load—and transient stability—stability under violent disturbance—might be greatly improved through rapid and generous response by the excitation system to the demand for large increase of field current by the alternator. Since the need for much faster excitation systems does exist, there has been developed to fill it a modification of the long-established vibrating-contact type of field regulator. This was the subject of the second paper. The differentiation of the new regulator from preceding practice is caused by the inclusion in it of means to hold the normally vibrating contacts in the closed position while the exciter current climbs in one step to, or as near to as is possible, that higher average value demanded for stability of the alternator under its new condition of load. Since 1920, when the general subject of excitation and machine stability was reviewed at the White Sulphur Springs convention, any paper bearing on this or related matters can be confidently counted upon to stir up a keen discussion, and, as just implied, the meeting under notice proved no exception. After Messrs. Park, Carothers, Nickle, Powell, Evans, Wagner, Ashbaugh and others had shivered their lances on one another's shields, Prof. Comfort A. Adams pointed out that the logical result of investigations into machine stability is the exact determination of the "dizzy edge" of instability and, following that determination, the approach of normal operation nearer and nearer to the edge in the desire to reduce ratio of output to weight of metal in machine design.

Since the introduction of the impedance relay in 1923 certain developments have come about in its design and in its application. These were reviewed in a paper by H. A. McLaughlin and E. O. Erickson. The methods of obtaining proper potential for the restraining elements without the use of high-tension potential transformers and the use of potential from condenser-type bushings were described. To make possible the use of low-tension potential, means for compensating for the voltage drop through power transformers and for the shifting of the secondary neutral point have been developed. These were described, as were also some special applications. Deprecation of the tendency to overenthusiasm regarding the capabilities of new devices was apparent in the discussion of this paper by H. P. Sleeper, W. H. Millan and O. C. Traver. All three agreed that in the purposes for which it was intended the inductive relay performed admirably, but that these purposes did not include all power-system relay applications. A preference for the classic method of balanced protection of parallel lines was voiced, this including the inductive relay as back-up protection after the failure of one of the parallel lines.

### AUTOMATIC SWITCHING

Some of the more common forms of automatic switching of incoming lines and transformers supplying power to alternating-current substations were described in a paper by A. E. Anderson. By making a few minor modifications in the schemes described it has been possible to control automatically a complete loop or ring system. The uses and the switching requirements of balanced or parallel incoming lines and of preferred-emergency equipments were discussed in some detail. The paper concluded with a brief discussion of automatic synchronizing and transformer switching.

J. B. MacNeill presented an interesting description of the design and performance of an improved type of moderate-capacity oil circuit breaker. Relatively high-power breakers having all three poles in a single round tank have been designed, and these, in addition to increase of rating for a given space, have shown improvements in performance over types previously available.

A simple method for reducing conductor vibration on transmission lines was presented in a paper on that general subject by Theodore Varney. In a previous Institute paper Mr. Varney had discussed the action of the wind on a suspended conductor and given rules for determining the wave length and frequency of the resulting vibration. Since the date of that presentation records have been kept of the wind action upon a large number of transmission lines equipped with different kinds of conductors and installed under various conditions. Data selected from these records were presented in the paper, which also included test results from experiments indicated by the character of the recorded information. In the analysis or solution of alternating-current problems it is frequently necessary to convert vector quantities from the exponential or polar forms into complex numbers or vice versa. The paper on vector calculating devices by M. T. Weinbach described some of them and gave examples of their use.

The planning of telephone exchange plans was covered in a paper by W. B. Stephenson, and tuned radio-frequency amplifiers were treated clearly and as simply as the subject would permit by R. F. Glasgow.

### IVES, PECK AND CULLEN CONTRIBUTE

The last item on the program of the technical sessions was a lecture by Dr. H. E. Ives on television. This lecture was open to the public and drew a large attendance. On the evening of the second day a popular talk on lightning, which was illustrated with lantern slides and motion pictures, was presented by F. W. Peek, Jr. This was reported last week on page 523. At the convention dinner-dance Charles E. Cullen, professor of law and business administration of Washington University, talked on "Sanity and Sane People."

---

## Business Men Inspect New East River Station

The New York Edison Company's East River station, which has now installed one-tenth of its ultimate capacity of almost 1,250,000 kw., was thrown open on March 9 to inspection by a party of representatives of civic and commercial associations, under the auspices of the Fourteenth Street Association. Vice-President Arthur Williams told the visitors of the coming addition of a 160,000-kw. machine now under manufacture by the General Electric Company, and explained some of the devices used, such as the water-filled steel tubes for furnace walls and the coal- and ash-handling towers on the river's edge.

"This new station, as planned," Mr. Williams said, "presents the greatest program for power generation that has yet been conceived. And this is only one of the several giant power plants now engaged in giving New York electric service. The plans for its construction will proceed for at least the next decade, as the station is designed to help serve increases in the utilization of electricity until 1940." The cost of the completed structure is expected to exceed $100,000,000, he said. When it finally operates at full capacity it will require for steam condensing purposes a total of 2,160,000,000 gal. of water every 24 hours. This is more than twice as much as Greater New York consumes daily. The completed station will be capable of filling the light and power needs, as of the present date, of any state in the United States with the exception of New York, Pennsylvania, California, Illinois, Ohio and Michigan, Mr. Williams observed, on the authority of United States Geological Survey statistics.

---

## To Promote Power Sales

*Commercial Section, N.E.L.A., Meeting in Chicago, Turns Thought to Competitive Power Situation—Refrigeration and Merchandising Also Features*

COMMERCIAL Section men of the National Electric Light Association held a two-day meeting last week at the Edgewater Beach Hotel, Chicago. Interest centered chiefly in the work of the merchandising, power and refrigeration committees. The first day was devoted to the committees on power, industrial heating, commercial cooking, refrigeration, domestic ranges and customer relations. The executive committee was in session the second day. No more meetings are to be held before the Atlantic City convention.

The power committee, under H. W. Derry, is engaged in an analysis of the trend of industrial power for the purpose of developing a graphic comparison of the use of steam, internal-combustion engines, private electric plants and purchased power. The manufacturers of steam and oil equipment, as Mr. Derry pointed out, are fighting for existence and perfecting improvements in efficiency that are making serious competition for electric power. Central stations must study the national trends and compare them with statistics on local conditions in order intelligently to direct power sales. Power load can no longer be taken for granted, he said. There is great need for trained man power in this field. S. L. Nicholson also pointed out the need for well-classified information on load characteristics, since conditions affecting load factor in many industries have greatly changed in recent years.

C. E. Greenwood, for the merchandising committee, reported very gratifying registrations in the "residence kilowatt-hour contest," entries for which close on April 1. Indications are that at least two hundred power companies will participate. This committee is about to announce an expanded program for concurrent appliance advertising by central stations, dealers and manufacturers for the season of 1928-1929. To the work of the intertrade conference, which has developed a statement of merchandising principles for the guidance of trade relations in electrical merchandising, a vote of appreciation was given. This agreement, which has been signed by officials of the various trades, will be submitted to the N.E.L.A. executive committee the latter part of this month for approval, before publication.

Chairman G. B. Richardson announced the plan for a twelve months' campaign of personalized direct-by-mail advertising, with neutral illustrations, which the refrigeration committee has prepared for use by local companies. Under this plan special mailing lists are to be sent to Dallas, where the folders and letters will be printed by a special process, each piece bearing conspicuously the name of the recipient. The range committee is at work on a similar advertising campaign.

W. H. Sammis announced the completion of the industrial heating committee's motion picture of industrial heat applications, which is to be sold or rented to member companies. The electrical advertising committee reported by wire the successful progress of its salesman's school, then in session at the Edison Lighting Institute in Harrison, N. J., with 163 salesmen in attendance.

The trend of wiring requirements was discussed by E. W. Lloyd and S. L. Nicholson, who both called upon the power industry to take a constructive rather than a defensive interest in the development of the National Electrical Code. W. H. Hodge reported on a movement being organized by about thirty trades and industries to stimulate the modernization of homes. A committee from the N.E.L.A. Commercial Section will be appointed to co-operate.

## New York Commission for Law on Sub-Meters

The annual report of the Public Service Department of New York, State Division, for the year ended June 30, 1927, filed with the Governor recently, says that in 867 of the 921 towns of the state electric franchises are in force or their exercise has been permitted by the commission. The report says that "progressive consolidation which has been taking place for the past decade has now reached the stage where the state is served by eleven principal groups. Interconnection between groups has progressed simultaneously to the point where it is possible now for energy to flow in almost every direction within the state."

After commenting on the rapid extension of rural electric service the commission makes reference to the practice of sub-metering, by which a landlord buys energy at wholesale and makes a profit by retailing it, sometimes at rates in excess of those approved by the commission, to his tenants. Concerning this practice, which has aroused great complaint—especially in Manhattan Borough, New York City—the commission says:

> The commission has referred in its annual report to the so called sub-meter, over which it has no jurisdiction. Complaints respecting sub-meters do not decrease. While there is a disposition on the part of some engaged in rendering service through sub-meters to improve conditions and to emulate service corporations in maintaining the meters in good condition, their number is relatively small. Not until such meters are placed under proper supervision will the public be fully and adequately protected.

A recent newspaper article put the number of sub-meters in Manhattan at 115,000, an increase of 40 per cent in five years.

# Briefer News

HIGH-VOLTAGE TRANSMISSION EXTENSION IN NORTH CAROLINA. — The Carolina Power & Light Company is expected soon to begin construction on 138 miles of 110,000-volt transmission lines from Sanford to the Cape Fear station, from Norwood to connect with existing lines, from Canton to Greenville, from Canton to Asheville and from Moncure to Sanford.

HEARING THIS MONTH ON ROYAL GORGE PROJECT.—The Colorado Public Utilities Commission has set March 29 at Pueblo to hear the petition of the Public Service Company of Colorado for permission to erect a hydro-electric plant in the Royal Gorge. Although the company says it will not mar the beauty of the gorge, there are several hundred petitions asking that the grant be denied.

ENGLISH RIVER SITE APPLIED FOR.—Application has been made by George Farlinger of Sioux Lookout, Ontario, to the Lands and Forests Department for a lease of the power rights at Ear and Manitou Falls, on the English River, at the western outlet of Lac Seul, near the Manitoba border. The site for which Mr. Farlinger seeks a lease is estimated to be capable of developing about 60,000 hp.

CHESAPEAKE & OHIO RAILWAY CONTRACTS FOR 9,000,000 KW.-HR. WITH VIRGINIA PUBLIC SERVICE.—A contract recently negotiated between the Virginia Public Service Company and the Chesapeake & Ohio Railway Company for electric service at all points along that road in the utility company's territory includes 126 items and involves approximately 9,000,000 kw.-hr., bringing an annual revenue estimated at $225,000.

CENTRAL HUDSON GAS & ELECTRIC GIVES $10,000 TO ENGINEERING FOUNDATION.—A contribution of $10,000 to the Engineering Foundation endowment fund has just been made by the Central Hudson Gas & Electric Corporation of Poughkeepsie, N. Y. In making this donation T. R. Beal, president of the company, says: "This amount was in fact earned by our employees by their more efficient operation of the physical properties under their care. It represents $10,000 of return premiums paid during the past year on accident insurance as the result of the company's excellent record in preceding years."

POWER CANAL PROVES DEATH TRAP FOR DEER. — A concrete-lined power canal belonging to the California-Oregon Power Company and located in the mountainous regions of southern Oregon is proving a death trap for deer, according to the game authorities. Nine-foot sloping walls render it impossible for the animals to get out of the canal when once they try to cross it, with the result that the brutes flounder about until they become exhausted and drown. The power company will probably construct bridges over the canal at intervals so that the deer may cross in safety.

NATURAL GAS MAY BE FUEL FOR CANADIAN PRAIRIE PLANTS.—The Calgary Power Company, which controls hydro-electric development on the Bow River in the Province of Alberta and has been spreading its lines over the southern part of the province, has taken an option on approximately 10,000,000 cu.ft. of natural gas in the Turner Valley field. Whether the gas is for steam-electric generation of power the company refused to say.

HOME ECONOMICS SCHOOL MAKES AUSPICIOUS START.—The first school of home economics to be established by any division of the National Electric Light Association was held recently at the Oklahoma A. & M. College, Stillwater, under direction of Dean Nora A. Talbot, with the co-operation of Miss Florence D. Schertz and Mrs. Bess Brooks. National and geographic division officials were present, and the school was declared an unqualified success.

RATES SLASHED IN SIXTEEN IOWA CITIES.—Reductions of 20 per cent, with a maximum charge of 10 cents a kilowatt-hour and no service charge, became effective on March 1 in sixteen northwestern Iowa communities which recently came into the Iowa Public Service Company electric distribution system. Among the cities benefiting are Cherokee, Clarion, Emmetsburg, Forest City, Eagle Grove, Humboldt, Ida Grove, Le Mars, Rockwell City, Storm Lake and Sac City.

PLANS FOR WORLD ENGINEERING CONGRESS TAKING SHAPE.—The American committee of the World Engineering Congress, appointed by Herbert Hoover as honorary chairman, will meet in Washington on March 22 to formulate plans for the participation of American engineers in the congress, which will be held for the first time in Tokyo in 1929. Tsuneo Matsudaira, Imperial Japanese Ambassador to the United States, will be the host at a dinner.

UTAH ENGINEERING COUNCIL COMMITTEE REPORTS ON BOULDER DAM.—Passage of the Swing-Johnson bill, or comparable legislation, is the most effective present means of so binding California to the upper states that any rights acquired in California will be subject to the Santa Fe compact. This is one of the conclusions the special committee representing the Engineering Council of Utah and another committee appointed by the president of the Utah Bar Association, engaged for six months in a study of the Colorado River problem, present in a report recently released. "The states should own and control the public waters, provision should be made for developments on the river eventually to come under state control, and Utah should become a party to the Santa Fe compact regardless of the number of states ratifying," the report says.

**Georgia Power Reduces Rate to Large Commercial Customers.**—The Georgia Power Company has filed with the Georgia Public Service Commission a reduced rate applicable to its large commercial customers. It is a combined light and power rate embodying a service charge plus a kilowatt-hour charge and permitting the use of one totalizing meter. The rate is applicable to those commercial customers whose combined lighting and power demand exceeds 50 kw. and which use power equal to 40 per cent of the total load.

**Victoria (Tex.) Plant to Be Tripled in Rating.**—The Central Power & Light Company has adopted plans for the installation at Victoria of a 9,000-hp. turbine and two 723-hp. boilers that will triple the present generating capacity of the plant, increasing it from 4,500 hp. to 13,500 hp. This new source of electrical energy not only will provide Victoria with an ample supply of power for years to come but will be available, through existing transmission lines, to a territory extending from Luling, Eagle Lake and El Campo on the north and east to Port Lavaca, Beeville and Kenedy on the south and west.

**Ohio Power Substation Being Raised to 45,000 Kva.**—Equipment in the Ohio Power Company's substation at Newcomerstown, Ohio, is being tripled at a cost of $330,470. More than 75 men are employed in revamping the station from a 15,000-kva. bank to a 45,000-kva. bank. Five counties—Holmes, Tuscarawas, Guernsey, Coshocton and Harrison—with 2,246 square miles of territory, will be served by the new plant when it is completed in May. As part of the project two new circuits to Cambridge are being built, as well as a new circuit to Coshocton. The station at Newcomerstown is also being rebuilt.

**New Unit for Grand Rapids, Mich.**—Vice-President Charles W. Tippy of the Consumers Power Company announces that the company means to install a 20,000-kw. turbo-generator at the Wealthy Street plant of the company in Grand Rapids. Mr. Tippy explained that the growth of business in Grand Rapids and Muskegon had compelled the company to abandon all thought of water-power development on the Muskegon River since more generating capacity will be needed within a period of twelve months. The program for the Wealthy Street plant contemplates eventually a maximum capacity there of 200,000 kw. At present an addition to the present turbine room will be built, also a boiler house and 250-ft. concrete stack. Two new boilers will supply steam at a pressure of 400 lb. These will be equipped to burn pulverized fuel. The new unit will virtually double the present station capacity.

**Another Interconnection for Pennsylvania.** — Work will start within a few days on construction of a 66,000-volt transmission line from Berwick, Pa., through Salem Township, back of Shickshinny, to the Hunlock Creek power plant. The line will connect the Berwick substation of the Pennsylvania Power & Light Company with the plant of the Luzerne County Gas & Electric Company and is one of the first connections to be made in that region between large companies.

**Southwestern Gas & Electric Plans New Arkansas Plant.**—Construction by the Southwestern Gas & Electric Company of a steam generating plant on Little River, one mille south of Horatio, Ark., to cost $3,000,000 and be completed in two years' time, is announced to begin soon. Electrical energy will be furnished from it to the towns in southwestern Arkansas and eastern Oklahoma whose lighting plants were recently purchased by the Southwestern Gas & Electric Company from the Dierks company. A contract to supply a large cement plant at Foreman is said to make the new generating station necessary.

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]**

Maryland Utilities Association—Emerson Hotel, Baltimore, March 23. G. S. Williams, 1005 Continental Bldg., Baltimore.

Southwestern Division, N. E. L. A.—Edgewater Gulf Hotel, Biloxi, Miss., April 3-5. S. J. Ballinger, San Antonio Public Service Company, San Antonio, Tex.

Nebraska Section, N. E. L. A.—Omaha, April 4 and 5. T. E. Browne, 1527 Sharpe Bldg., Lincoln.

Southeastern Division, N. E. L. A.—Miami, Fla., April 11-14. C. M. Kilian, 207 Bona Allen Bldg., Atlanta.

American Institute of Electrical Engineers — Baltimore regional meeting, April 17-19; New Haven regional meeting, May 9-11. F. L. Hutchinson, 33 West 39th St., New York.

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities —Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association —The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

**Watertown, N. Y., Now Generates 7,500 Hp.**—With the placing in service of the third generating unit of the Watertown (N. Y.) municipal hydro-electric plant, 7,500 hp. is available, the waters of the Black River being at a high point, with prospects of a heavy flow during the next three months. The city sells all surplus power to the Northern New York Utilities and is anticipating that the amount received in the next year will be more than $100,000.

**Dallas Wires All Underground.**—The Dallas Power & Light Company, through C. W. Davis, vice-president and general manager, announces that its underground wire system, which has been in the process of construction for seven years, has been virtually completed. Construction of the underground system, which has followed the best models, has enabled the company to remove almost three hundred poles from the business district, with thousands of wires, which, with the rapid growth of the city, were becoming so numerous as actually to impede progress.

**First "School of Electrical Advertising" Is Held.**—Harrison, N. J., was last week the scene of a four-day "school of electrical advertising" held in the auditorium of the Edison Lamp Works of the General Electric Company, the Westinghouse Lamp Company co-operating. More than two hundred delegates, representing sign manufacturers, power companies and maintenance and accessory men in the East, attended. The gathering was addressed by C. J. Eaton, chairman of the electrical advertising committee of the N.E.L.A., and Earl Whitehorne, commercial editor of the Electrical World. A second school will be held at Nela Park, Cleveland, on March 19-22.

**More Rate Reductions in Kansas.**—Voluntary rate reductions of from 20 to 25 per cent have been announced for the city of Atchison by the Kansas Power & Light Company, with headquarters in Topeka. New voluntary reduced rates have also gone into effect at Salina, served by the United Power & Light Corporation of Abilene. The former rate, 9 cents for the first 50 kw. and 5 cents for all in excess, has been changed to an 8-cent top rate for the first 30 kw., 6 cents for the next 30 kw.-hr., 5 cents for the next 40 kw.-hr. and 3 cents for all over 100 kw. A revised schedule of residence and commercial lighting rates has been placed in effect at Manhattan as a result of an agreement between the City Commission and the United Power & Light Corporation. The new rates are about 10 per cent lower than those provided in the franchise that was voted down.

Patrolling Transmission Lines by Airplane. — Addressing the Electric Club of Toronto recently, A. E. Davidson, engineer of the transmission department of the Hydro-Electric Power Commission of Ontario, forecast the use of airplanes to patrol the 230-mile, 220-kv. power line from the Gatineau Power Company's developments on the Gatineau River to Toronto, when construction of the line is completed. Much of the area through which the transmission line will run is rough and inaccessible, and inspection by air would be more rapid and more thorough.

High-Power Line to Be Built from San Bernardino to Seal Beach, Cal.—The Southern Sierras Power Company, a subsidiary of the Nevada-California Electric Corporation, has authorized immediate construction of a 110-kv. power line between San Bernardino and Seal Beach, Cal., to cost $750,000. The line will extend over 58 miles and join the company's San Bernardino's substation with the Los Angeles Gas & Electric Company's Seal Beach generating station, giving the Southern Sierras company an outlet for hydro-electric power generated in the High Sierras and making possible in the opposite direction a direct supply of steam-generated power from the Los Angeles plant.

Porto Rico Railway, Light & Power Gets Franchise for Water-Power Plant.—By the signature of the Governor of Porto Rico to a franchise granted by the Public Service Commission, the Porto Rico Railway, Light & Power Company has gained "authority to utilize the waters and waterfalls of the Hicaco, Cubuy, Prieto, and Sabana Rivers and their tributaries, which form the so-called 'Blanco' River, in Naguabo, Porto Rico, and the so-called Rio Blanco development, and to construct, maintain and operate a hydro-electric plant and the necessary transmission lines." This accomplishes an object for which the company, of which Frederick Krug is general manager, has for some time been striving.

Insull Company Leases Coming Black River (Mo.) Power.—The Middle West Utilities Company has signed a twenty-year lease on the 30,000-hp. hydro-electric plant to be erected on the Black River, 3 miles southwest of Piedmont, Mo., near Poplar Bluff, by the Black River Hydro-Electric Company. The dam and power plant will cost approximately $4,500,000, according to plans prepared by the W. A. Fuller Company, St. Louis. Construction contracts will be awarded soon after federal and state licenses, now pending, are awarded. The reservoir to be created will be 21 miles long and a quarter of a mile to a mile and a half in width.

# Recent Court Decisions

Proper Division Between County and City of Tax Paid by Holder of Light and Power Franchise. — The District Court of Appeal in California has adjudged proper the division between Tulare County and the city of Dinuba (plaintiff and defendant) of a tax paid by the holder of an electric light and power franchise which caused to inure to the city a sum equal to the tax on the same proportion of gross receipts of the company from consumers in the city which the total value of all pole lines of the company's entire system bore to the total investment of the company. (263 Pac. 249.)*

Contributory Negligence of Workman Splicing Charged Wires Without Gloves Held for Jury.—The Supreme Court of New Jersey has determined, in Brice vs. Eastern New Jersey Power Company, that in the case of a workman who was killed while attempting without gloves to splice a broken fire-alarm wire on a pole supporting also the company's transmission wire the question of contributory negligence was properly submitted to the jury inasmuch as evidence showed that under normal conditions there would have been no current in the electric wire, and since it appeared that the wires came into contact because of the sagging of the electric wire at the distance of one block away (unknown to the workman), which resulted in the insulation wearing off. (139 At. 885.)

Directed Verdict Properly Elicited by Incredible Testimony.—In Simmons vs. Terrell Electric Light Company a boy testified that a hanging wire, not charged, belonging to the company struck him in the eye so hard when he came into contact with it, while walking with his mother, that he had to pull it out of the eyeball. As there was no claim that the end of the hanging wire was bent and as a physician swore that the boy's eyeball had been pierced from the side nearest the ear, the Court of Civil Appeals of Texas held this testimony incredible and to have justified an instructed verdict for the company. The court found, further, that although the electric company was charged with knowledge of the age, condition and weight of its wires, the strength of their supports and their location as regarded possible injury from limbs of trees, there was no evidence that the company knew of the hanging wire, which had apparently been broken less than an hour, or that it had been negligent in the respects just named. (1 S.W. [2d] 513.)

Right to Recover for Injury from Electric Company Furnishing Emergency Service Only.—In Rhymes vs. Eastern Texas Electric Company, the plaintiff, a workman, sued for damages because of injury received when to repair insulators he went on a pole over which the electric company furnished emergency service to his employer and came into contact with a defective switch. The electric company, claiming a breach of contract by the employer, the Texas Company, filed a cross-bill against the latter, asserting that no emergency warranting Rhymes' presence on the pole existed. The Court of Civil Appeals of Texas affirmed a judgment for the Texas Company, but reversed and remanded one for the plaintiff as against the Eastern Texas Electric Company on the ground of prejudicial errors in charges to the jury. The upper court decreed, however, that the defendant, having installed a jumper to carry energy around the switch and being under contract to keep its appliances in safe condition, could not claim reimbursement from the consumer, even though the latter had not kept a contract to install a switch on its premises and had refused the defendant permission to cut off the current in order to repair switch. (1 S.W. [2d] 688.)

# Commission Rulings

Can Earning Power of Non-Existent Hydro Plant Be Evaluated?—The Public Service Commission of Oregon is contemplating the advisability of adopting a rule affecting the valuation of utility properties which, if approved, will require the engineering department to appraise water-right holdings and find a valuation of hypothetical electric plants which may be constructed in connection with the water holdings. A serious obstacle in the path of such a program, however, is that neither the regulatory department nor the state engineering body possesses any standard by which a water right can be valued. The Oregon law governing the control of streams does not concern itself with the value of water rights, and the commission engineers express grave doubts as to their ability to pass upon the earning power of an imaginary hydro-electric utility.

Utility Company Not Compelled to Operate at Loss.—Authority has been granted by the Montana Railroad and Public Service Commission to abandon the traction system in the city of Helena because of a failure to earn a fair return. The commission said that this was the first time since its establishment that the question of granting approval to a complete abandonment and discontinuance of a street-railway system had been presented. The fact that the company had devoted its property to a public use by operating the system on and after the expiration date of the franchise did not, in the opinion of the commission, constitute, under the facts in the record, an irrevocable or absolute dedication of its property to the use of the public. The commission said: "Rather, is its devotion of its property to a public use predicated upon the assumption and condition that the public shall supply sufficient traffic on a reasonable basis to yield a fair return; and when it develops, as it is here shown to have developed, that future operations must be at a loss, then the company has the unquestioned right to discontinue operations and salvage what it can by dismantling the system. To compel petitioner to operate its system at a loss or to give up the salvage value would be to take its property without the just compensation which is a part of due process of law. The rule has been aptly stated by the Supreme Court of Montana in the city of Helena vs. Helena Light & Railway Company, thus: 'It is now well settled beyond controversy that a public utility cannot be compelled to operate its entire business, or a branch of its business, at a loss, in the absence of a statute or contract requiring it to do so.'"

# News About Men of the Industry

Prof. R. C. Wallace of the University of Manitoba has been made chairman of the Manitoba Hydro-Electric Commission.

C. H. Dahl, formerly assistant general manager of the Winnipeg Electric Company, Winnipeg, Man., is now assistant general manager of the company in charge of operation.

Karl B. Norris, vice-president and general manager of the Wetmore-Savage Electrical Supply Company, Boston, has been elected president of the Saugus (Mass.) Trust Company.

E. J. McGarrell, formerly connected with Stone & Webster, Inc., Boston, has joined the meter department of the Elmira (N. Y.) Water, Light & Railroad Company in the capacity of electric meter inspector. Mr. McGarrell is a graduate of the Worcester Polytechnic Institute.

J. H. Shearer, president of the Pennsylvania Central Light & Power Company, has been elected a member of the board of directors of the Pennsylvania State Chamber of Commerce. Mr. Shearer has been active in the work of the chamber for several years.

William Noyes of Boston, well known in the hydro-electric engineering field, has been appointed operating engineer of the Public Service Company of New Hampshire with headquarters at Manchester. Mr. Noyes will make a complete study of the company's system in regard to water and load conditions.

Frank A. Rumatz, Chicago, formerly chief engineer for the Western United Gas & Electric Company, Aurora, Ill., has been made chief engineer for the Tecumseh plant of the Kansas Power & Light Company, with headquarters in Topeka. The Tecumseh plant is the company's chief generating station.

John L. Tudbury, manager of the Salem Gas Light Company, has been made manager of the Salem Electric Lighting Company as well as general manager of the Beverly Gas & Electric Company. Mr. Tudbury's first connection with the public utility business was with the Lynn Gas & Electric Company. It was in 1911 that he removed to Salem as superintendent of the Salem Gas Light Company.

Herbert S. Hinrichs, for more than two years field engineer in charge of rural electrical experiments at Larned, Kan., under the auspices of the Kansas Committee on the Relation of Electricity to Agriculture, has become agricultural engineer for the Kansas Power & Light Company, Topeka. Mr. Hinrichs, under whose direction nine electrified farm experiments have been conducted, expects to assume his new position on completion of his present work at Larned about the middle of March. A graduate of Kansas State Agricultural College, Manhattan, he combined with his technical knowledge a thorough understanding of farm problems in Kansas.

## *Dr. Davis to Head Stevens Institute*

Dr. Harvey N. Davis, professor of mechanical engineering at Harvard University and consulting engineer, has been elected president of Stevens Institute of Technology, Hoboken, N. J., succeeding the late Dr. Alexander C. Humphreys. He will assume his new duties Sept. 1. Dr. Davis was born at Providence, R. I., in 1881 and was educated at Brown and Harvard universities, receiving the degree of Ph. D. from the latter in 1906. He was an instructor at Brown in 1901-02 and has been teaching at Harvard since 1904. During 1917-18 he was engineer in the turbine department of the Lynn works of the General Electric Company and in the latter year was occupied in engineering research for the U. S. air service. He has been consulting mechanical engineer of the U. S. Bureau of Mines since 1921. He is a fellow of the American Academy of Arts and Sciences and a member of many other learned and professional societies. Dr. Davis is the author with Prof. L. S. Marks of "Steam Tables and Diagrams" and with Prof. N. Henry Black of "Practical Physics for High Schools." He is also the author of various papers dealing with thermodynamics.

*H. N. Davis*

---

Louis Larsen, for 26 years with the Sundh Electric Company, Newark, N. J., has resigned. Mr. Larsen started with the company when it was originally organized by Mr. Sundh. Since November, 1922, he has been general manager and prior to that time was works manager and chief engineer. During his period of service with the company Mr. Larsen has been granted many patents on control equipment. He represented his company as executive member in the old Electric Power Club and later in the National Electrical Manufacturers' Association. Mr. Larsen as yet has made no announcement regarding his future plans.

Walter F. Hudson, director of industrial developments of the Utica Gas & Electric Company, has been appointed director of the industrial bureau of the Utica Chamber of Commerce. Mr. Hudson joined the local utilities as chief engineer in 1920. He is secretary of the Empire State Gas and Electric Association.

Walter W. Kennedy, who has been connected with the executive department of the Birmingham Electric Company, Birmingham, Ala., since 1925, has been appointed assistant to J. S. Pevear, vice-president and general manager. Mr. Kennedy was admitted to the bar and practiced law in the firm of Bradley, Baldwin, All & White until he affiliated himself with the Birmingham company.

William H. Onken, Jr., editor of the Electrical World, has been appointed by Bancroft Gherardi, president of the American Institute of Electrical Engineers, one of the representatives of the Institute at the dedication of the Louvain Memorial at Louvain University, Belgium, July 4, 1928. On that day the new memorial library at Louvain, presented by the Engineering Foundation, together with the clock and the carillon in its tower, which constitutes the memorial to engineers of the United States who gave their lives in the World War, is to be dedicated. Other representatives are Edward Dean Adams, John W. Lieb and Michael I. Pupin.

Dr. Andrew M. Soule, president of the State College of Agriculture, Athens, Ga., has been named president of the Southern Appalachian Power Conference. The selection of Dr. Soule brings to the head of that body a man who has taken an intense interest in the power and industrial development of the South, devoting his attention especially to the extension of electric power to the rural sections and farms. Through the engineering department of the college, he is carrying on extensive investigations relating to electrification of farms and electrical apparatus and equipment suitable for use on the farm.

L. L. Ellis, assistant chief construction engineer for the San Joaquin Light & Power Corporation for the past nine years, has resigned to become district sales manager at Fresno for the Yosemite Portland Cement Corporation, Merced, Calif. Mr. Ellis has been identified with construction in the Joaquin Valley since 1901, superintending construction for the Mount Whitney Power Company on the Kaweah River. He built the first concrete power house for the San Joaquin Light & Power Corporation in 1905 and has superintended the building of the Kerckhoff development, the Balch plant and other structures.

B. Green has been named superintendent of the Niagara, Lockport & Ontario Power Company at Olean.

C. F. Crowley, for seven years Cleveland representative of the Hatfield Electric Company, contracting electrical engineers with offices at Chicago, Indianapolis and Cleveland, was elected vice-president of the company at the annual meeting of its board of directors.

Allyn B. Tunis, secretary of the Public Utilities Association of Virginia, has been made director of the Virginia Committee on Public Utility Information, organized early this year, with headquarters at Richmond. Mr. Tunis has had wide experience in newspaper work in Richmond, elsewhere in the South and in New England.

R. B. Lillie, manager of the Antigo division of the Wisconsin Valley Electric Company, has been appointed manager of the Stevens Point division to succeed M. H. Montross, who has assumed new duties at Wausau. Mr. Lillie has been associated with the Wisconsin Valley utility for the past fifteen years.

H. A. Walsh has been appointed power sales engineer of the Baton Rouge Electric Company, Baton Rouge, La. Mr. Walsh was formerly connected with the Stone & Webster interests at Ponce, P. R., and more recently with the Gulf States Utilities Company at Beaumont, Tex., also a Stone & Webster property.

C. E. Blackwood, superintendent of the Southwest Power Company at Springdale, Ark., has resigned to enter business at Fayetteville, Ark. C. R. Reaser, formerly located at Prairie Grove, will succeed Mr. Blackwood. J. C. Black, superintendent at Rogers, will have supervision of the Springdale district.

Frederick Nolte, who has been connected with the Wisconsin Valley Electric Company at Antigo, has been appointed manager of that division to succeed R. B. Lillie, at the present time manager at Stevens Point. Mr. Nolte has been affiliated with the Wisconsin Valley company since 1924 and was the purchasing agent previous to his transfer to Antigo.

Robert W. Adams, formerly manager of the General Electric Company's sales office at Providence, R. I., has been appointed head of the central-station department of New England. He will be responsible for the Northeastern territory, with offices in Boston, Mass. Mr. Adams is a graduate of the electrical engineering course at Worcester Polytechnic Institute, Worcester, Mass., and has been with the General Electric Company since 1908. He was president of the Providence Engineering Society in 1917-18 and is the inventor of the Adams transmission line calculator.

Frank S. Root has joined the power sales engineering staff of the New England Power Company, with headquarters at Worcester, Mass. Mr. Root was for some years in charge of power sales activities for the Fall River (Mass.) Electric Light Company, and until coming to Worcester occupied a similar post in the organization of the Central Hudson Gas & Electric Company. He was active in the New England Association of Central Station Power Engineers from the time of its organization until leaving for New York State.

H. B. Heryford has been appointed manager of the San Joaquin division of the Pacific Gas & Electric Company to succeed the late Charles H. Northcutt. A native of California, Mr. Heryford has spent 25 years in the public utility industry. In 1903, starting with the Colusa Gas & Electric Company, he rose to the management of that company in three years. He became manager of the Chico district of the Pacific Gas & Electric Company three years later and in 1921 was appointed to the managership of the West Side division.

DeWitt Clinton, formerly treasurer of the Worcester Gas Light Company, is now secretary and assistant treasurer of the New England Gas & Electric Association, part of the Associated System. Mr. Clinton has been identified with the public utility industry since 1913, when he resigned as city treasurer and collector of taxes of Worcester to become secretary and treasurer of the Worcester Gas Light Company. Mr. Clinton's new duties include the treasurership of the Cambridge Gas Light Company, the Cambridge Electric Light Company and the Cape & Vineyard Electric Company.

## Obituary

C. H. Johnson, representative of the National Pole & Treating Company, San Francisco, died March 2. Mr. Johnson had been in ill health for some months.

Watson F. Blair, a director of the Commonwealth Edison Company, Chicago, died of bronchial pneumonia Feb. 7 at the age of 73. He had served on the directorate of the Commonwealth Edison Company for thirteen years. Previous to his retirement from active business some time ago, Mr. Blair was prominent in the Chicago banking field and as a grain commission merchant on the Board of Trade.

Jesse Lorenzo Hinds, founder and honorary president of the Crouse-Hinds Company, Syracuse, N. Y., died at his winter home in St. Petersburg, Fla., March 9. Removing to Syracuse from Binghamton, N. Y., where he was born, Mr. Hinds established the Electric Engineering & Supply Company in 1890. He had formerly been associated with business enterprises in Yonkers and Ilion, N. Y.; Alexandria, Va.; Great Bend, Pa., and Dayton, Ohio. The Crouse-Hinds organization was formed in 1897 when Mr. Hinds joined with Huntington B. Crouse of Fairville. Mr. Hinds retired from active duties in 1910.

James W. Harris, who has been connected with Alfred Wiseman, Ltd., mechanical and electrical engineers of Birmingham, England, died Jan. 14. After receiving some practical engineering training in England, his native country, Mr. Harris engaged in some work on power plants in India, China, Japan and in America on the Pacific Coast. He served the West Kootenay Power & Light Company, Bonnington Falls, B. C., and then joined the Westinghouse Electric & Manufacturing Company at East Pittsburgh, subsequently returning to Trefford Park, England. Mr. Harris was a member of the American Institute of Electrical Engineers.

Charles Vernier, chief engineer of the Macintosh Cable Company, Ltd., Liverpool, England, died Jan. 9, of pneumonia, following a nervous breakdown. At the time of his death Mr. Vernier held a position of prominence in engineering circles in England. He was in the course of his engineering career affiliated with the Brockie Pell Arc-Lamp Company, the Cork Electric Tramways & Lighting Company and the Newcastle-on-Tyne Electric Supply & Associated Companies. Mr. Vernier was active in the affairs of the Institution of Electrical Engineers, having held many of its important executive offices. He was elected a fellow of the American Institute of Electrical Engineers last June.

William J. Meyers, secretary of the United Electric Light & Power Company, New York, who had been absent from his office for many months owing to a lingering illness, passed away suddenly at his home in Westfield, N. J., Tuesday, March 13. Mr. Meyers, who was in his 59th year, was born in Caledonia, Mich., and was graduated from the Michigan Agricultural College in 1890 and obtained the degree of bachelor of laws from the University of Michigan in 1900. He was statistician of the second district Public Service Commission of New York from 1907 to 1910 and held a like position with the Interstate Commerce Commission until July, 1917. He then became secretary of the United Electric Light & Power Company. He was a very active member of the National Electric Light Association, having served as chairman of an important national committee, and was also a member of the American Gas Association.

# Financial and Statistical News

## *Utility Stocks in New Lead Bond Prices Tend Upward*

RECOVERING from the heavy selling movement of two weeks ago which brought market averages down several points in almost all groups, power and light stocks have not only reached previous levels but are taking a new lead. Common stocks of a group of companies representing more than one-third of the industry, in total assets, showed a gain of one point this week over last and of nine points since the beginning of the year. Prominent in the upward movement are Middle West Utilities, Detroit Edison, Commonwealth Edison, etc.

Preferred stocks have remained relatively quiet, with a steady trend toward marginally higher prices. Demand for the better class preferred issues is reported to be consistently good.

Power and light bond prices are also tending upward if less rapidly than a few months ago. The number of new bond issues is considerably below that of last year at this time. The volume of building and construction is lower in most parts of the country than the 1927 program.

## Hydro-Electric Power in Norway

Norway has more potential water power than any other European country. According to official statements, about 12,500,000 hp. could be developed continuously. This does not include waterfalls of less than 1,000 hp., which are estimated to amount to about 1,000,000 hp. Through regulation of the flow by damming the lakes, the total could easily be brought as high as 15,000,000 hp., of which about 2,000,000 hp., or 15 per cent, has been developed. Most of the developed power is owned by industrial concerns and utilized for manufacturing purposes, such as the fixation of atmospheric nitrogen and the production of aluminum, ferro-alloys and other substances.

## Allis-Chalmers Earns $10.02 on Common

Although sales billed by the Allis-Chalmers Manufacturing Company during 1927 were 8.7 per cent larger than the 1926 total, being $33,352,252, net income carried to surplus decreased from $3,596,891 to $3,182,472, a drop of over 11.5 per cent. Expenses increased almost 10 per cent. Earnings per share, however, showed an increase from $9.48 on common stock in 1926 to $10.02 per share during the calendar year 1927.

In accordance with a fairly general industrial contraction, unfilled orders at the end of 1927 were $10,013,114, as against $11,634,711 a year previous. The bookings of new business during 1927 totaled $30,651,807, contrasted with $32,170,181 in 1926, which was a 4.7 per cent decrease.

The working capital of the Allis-Chalmers Manufacturing Company at the end of 1927 was $21,241,058, as against $27,289,820 a year previous, the shrinkage being due to retirement of the preferred stock and acquisition of the Pittsburg Transformer Company. Total assets on Dec. 31 last amounted to $62,114,321.

Sales billed and net income for the past two years were as shown in the accompanying table.

| | 1926 | 1927 |
|---|---|---|
| Sales .......... | $30,682,542 | $33,352 252 |
| Net ............ | 3,596,891 | 3,182,472 |

## Westinghouse Electric Dividend

The payment of the regular dividend was voted by the board of the Westinghouse Electric & Manufacturing Corporation at its meeting deferred from Feb. 29 and held March 14. The next meeting will be March 28.

## Middle West Utilities Earns $15.12 on Common Stock

CONTINUING its steady, consistent increase in earnings, maintained over a long period of years, Middle West Utilities shows a gain of 15.7 per cent in parent company earnings, of 11.9 per cent in gross earnings of subsidiaries and of 16.1 per cent in net earnings of subsidiary companies. In keeping with most of the companies, this increase, although attractive, is much smaller than the 1926 record of growth in so far as subsidiary companies are concerned, but the earnings of the parent company showed a larger growth last year. In 1926 parent company earnings expanded 12.1 per cent, subsidiaries' gross 42.7 per cent and subsidiaries' net 55.9 per cent.

Surplus earnings, after payment of preferred and prior lien dividends, interest and administration expenses, were $6,988,401 in the case of the parent company, or the equivalent of $15.12 per share on the 462,079 shares of common stock issued and outstanding Dec. 31 last. This compares with $14.44 per share earned on 435,736 shares a year previous.

Customers served by subsidiaries at the end of 1927 were 1,062,773, as compared with 984,786 in 1926, an increase of 7.9 per cent. The output of electricity was 2,354,241,551 kw.-hr., against 2,054,497,637 the previous year, a gain of 14.6 per cent. Subsidiary companies spent $6,502,343 for maintenance of their properties and appropriated from income $4,120,359 for retirements, the total for depreciation and maintenance being 12.7 per cent of gross operating earnings.

The dividend on the company's common stock was increased from $6 to $7 per share, to be effective with dividend payable May 15, 1928. This payment, in accordance with charter provisions, will entitle 7 per cent cumulative preferred stock of $100 par to a dividend of 7 per cent and 1 per cent additional.

The common stock of the Middle West Utilities is today quoted around 133, which compares with 124 at the beginning of the year, 110 a year ago and 119 two years ago. It has not appreciated in relation to the growth in earnings, nor in relation to the stock increase of many less advantageously situated companies.

Considerable improvement was shown in operating conditions during 1927. Fuel consumption per kilowatt-hour generated decreased by one-third of a pound of coal. Steam generation increased 20.3 per cent during the year and hydro generation 17.3 per cent, making a total increase of 18.9 per cent. In face of this, fuel used increased only slightly over 5 per cent. Cost of residence and commercial service to customers of subsidiaries has dipped sharply below the pre-war level and consequently revenue per kilowatt-hour is now considerably below that level.

## Georgia Power Seeks Funds for Improvements

The Georgia Power Company has asked permission of the state public service commission to issue 70,000 additional shares of $6 preferred stock similar to the issue of 30,500 shares recently sold. In submitting a statement to the commission showing that the original issue of stock had been exhausted, Preston S. Arkwright, president of the company, declared that the distribution had been made with the idea of gaining for the company the interest and support of the general public. The sale was made to citizens in 110 Georgia counties, he stated. No person had been allowed to buy more than 25 shares and the sale had been at an average price of $97.52 per share. The present market price of the stock is $105. Employees are allowed $1 per share for stock distribution. The new issue will be sold at not less than $95 per share without par value, and the proceeds will be distributed over the state in improvements and the rehabilitation of plants already purchased and owned by the power company.

## Electrification in Russia

The progress of electrification in Russia is shown by statistics published in a recent issue of the *Economic Review* of the Soviet Union. While the general industrial development of the Union has surpassed by a small margin the pre-war level, the production of electrical energy by regional and local public utility stations is about three times the pre-war figure. The number of electric power installations in industrial enterprises has also greatly increased.

Production of electric energy by public utility stations and the capacity in operation during the past five years were:

| Fiscal Year | Kilowatt-Hours | Kilowatts |
|---|---|---|
| 1922–23 | 905,000,000 | 478,000 |
| 1923–24 | 897,000,000 | 498,185 |
| 1924–25 | 1,132,000,000 | 538,026 |
| 1925–26 | 1,470,000,000 | 618,862 |
| 1926–27 | 2,100,000,000 | 733,635 |

In 1913 the output was 690,000,000 kw.-hr. and the capacity 328,000 kw.

The program of the State Planning Committee calls for the following output by public utility stations during the next few years:

| Fiscal Year | Kilowatt-Hours |
|---|---|
| 1927–28 | 3,050,000,000 |
| 1928–29 | 4,100,000,000 |
| 1929–30 | 5,550,000,000 |
| 1930–31 | 6,950,000,000 |

The output of electric energy by all power stations in the U. S. S. R. last year was 4,112,000,000 kw.-hr., an increase of 27.7 per cent over 1925-26. Of this amount, factory power plants produced 1,950,000,000, railway and others the remaining 62,000,000 kw.-hr. The total is expected to increase on the average about 25 per cent during each of the next few years and to attain 10,000,000,000 kw.-hr. in 1930-31.

The capacity of public utility stations in operation last year was divided among 640 local stations with an aggregate capacity of 235,000 kw. and eighteen large urban and regional stations totaling 498,635 kw.

**METROPOLITAN EDISON INCREASES COMMON DIVIDEND.**—Directors of the Metropolitan Edison Company have declared a quarterly dividend of $2 per share on the common stock, no par value, payable March 24 to holders of record March 15. This places the common stock on an $8 annual dividend basis, compared with $7 per annum previously.

**CINCINNATI GAS & ELECTRIC ANNOUNCES REFINANCING PLAN.**—A refinancing plan, which calls for the redemption of the outstanding bond issues of the Cincinnati Gas & Electric Company and their replacement with new 5 per cent bonds, has just been decided upon by the directors of the company. Among the issues outstanding are: First mortgage 5 per cent bonds which total $11,469,000; sinking fund, series "B," bonds amounting to $5,818,000 and sinking fund, series "C," bonds totaling $5,401,500. These will be redeemed as of April 1 at their individual call prices, according to an announcement made by Charles D. Jones, president. The better money conditions make possible the replacement of the bonds with other issues at a lower rate of interest, the officials pointed out.

## *Stock Quotations of Electric Light and Power and Manufacturing Companies*

(Prices on New York stock market unless otherwise noted. Unless otherwise noted the par, stated, or preference value of stock is $100.)

| Companies | Bid Price Tuesday March 13 | Low 1928 | High 1928 |
|---|---|---|---|
| ABITIBI PWR. & PAPER, com., new — no par | 75¾ | 72 | 81 |
| Ala. Pwr., $7 com. pf.—no par | 115 | 114½ | 115½ |

## New Utility Financing Active

Electric light and power financing during the past week has been unusually active, a total of $41,925,000 having been recorded. Six individual issues contributed to this substantial sum. The largest offering was made by the Metropolitan Edison Company in the form of first mortgage gold bonds, priced at 99½ and interest, to yield about 4.52 per cent, a piece of financing involving a total of $23,000,000. Proceeds will be used to retire $20,545,500 bonds bearing higher rates of interest and for additions and betterments.

First mortgage and refunding gold bonds of the San Antonio Public Service Company were offered to the amount of $7,500,000, the price being 97½ and accrued interest to yield about 5.16 per cent.

The Memphis Power & Light Company made an offering of first and refunding mortgage gold bonds, series C, at 96½ and accrued interest, to yield about 4.70 per cent.

First lien and general mortgage gold bonds of the Utah Power & Light Company were offered to the amount of $5,500,000 at 96¾ and interest, yielding 4.79 per cent. These bonds, dated Feb. 1, 1928, and maturing Feb. 1, 1944, will be secured by a general mortgage on the entire physical property, franchises and rights of the company.

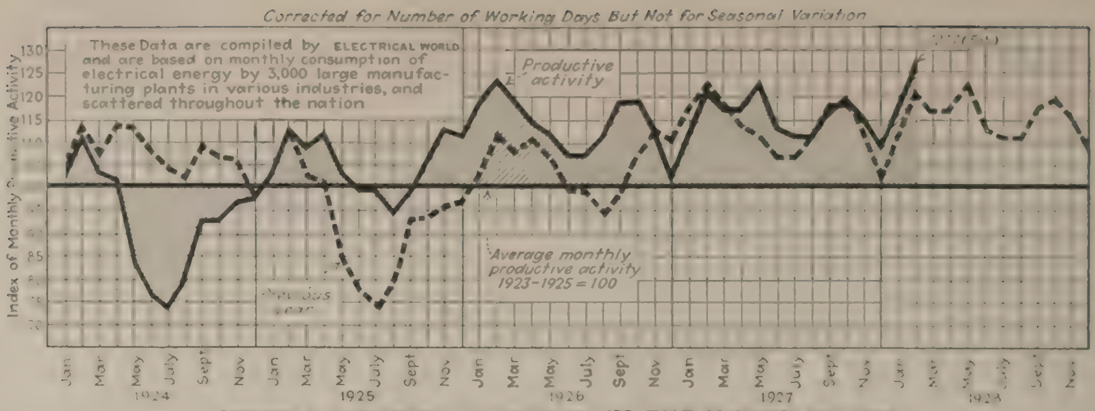
The West Texas Utilities Company issued 25,000 shares of $6 cumulative preferred stock (no par value) at $96 per share and accrued dividend to yield 6.25 per cent.

The Orange & Rockland Electric Company issued first mortgage gold bonds at 99½ and accrued interest, to yield over 5 per cent, the offering involving a total of $1,250,000.

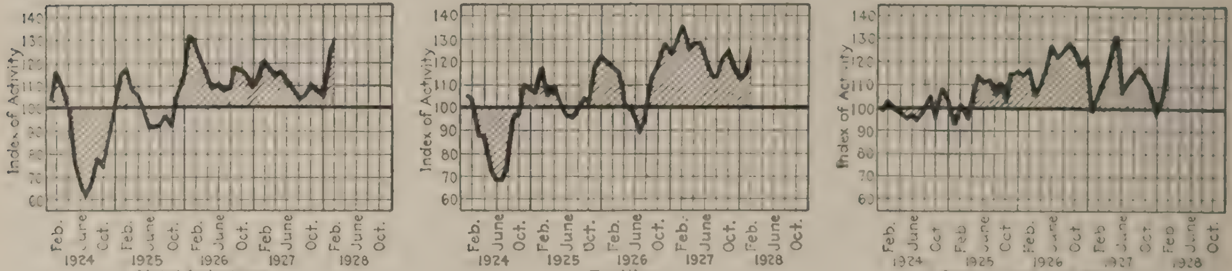
An electrical manufacturing company was also represented in the week's new offerings, the Cutler-Hammer Manufacturing Company having issued 75,000 shares of common stock. The price of this stock was $47.50 per share. Proceeds will be used toward the retirement of all of the outstanding preferred stock of the company, which will be called for redemption May 1, 1928.

---

COMMUNITY POWER & LIGHT CALLS STOCKS.—The board of directors of the Community Power & Light Company has voted to call for redemption all of the company's outstanding first preferred stock, $7 dividend series, and participating preferred stock, $8 dividend series, at the redemption price of $110 per share and dividends.



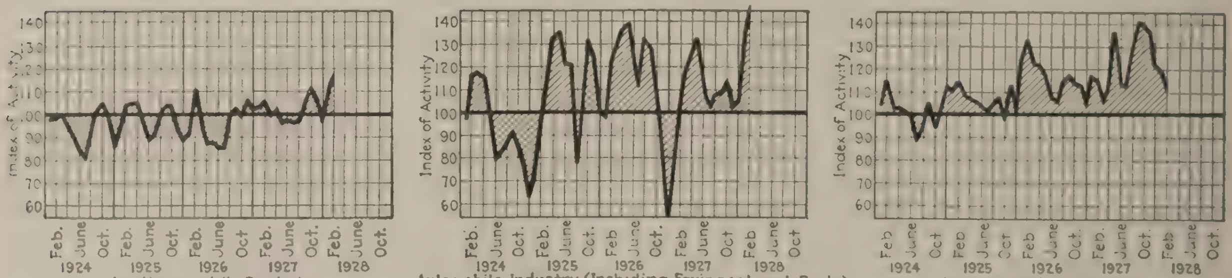
GENERAL INDUSTRIAL ACTIVITY IN THE UNITED STATES



Metal Industries

Textiles

Stone, Clay, and Glass



Leather and its Products

Automobile Industry (Including Equipment and Parts)

Lumber and its Products

PRODUCTIVE ACTIVITY IN THE PRIMARY INDUSTRIES OF THE UNITED STATES

# Industrial Production Increased 16 Per Cent

## More Than Normal Seasonal Increase in Productive Operations Since the Opening of the Year—All Groups Report Increases Over January

CONSUMPTION of electrical energy by the manufacturing plants of the nation as reported to the ELECTRICAL WORLD indicates that the rate of general industrial production has been materially increased since the opening of the year. The February rate of general production was 16.2 per cent over December and 7.8 per cent over January, a rate of increase comparable with that recorded for the same period in 1927, but materially exceeding that recorded in 1924, 1925 and 1926. It would appear that American industry as a whole has experienced an unusual upward swing since the opening of the year which should do much toward relieving the unemployment reported during December and January.

All sections east of the Rockies have materially increased their rate of production since December. New England, which has been reporting operations at a low ebb for several months, witnessed a February rate of productive activity about 23.7 per cent over December, due very largely to an increase in the operations of the textile mills of over 21 per cent during the two-months period. The manufacturing plants of the Middle Atlantic States reported February operations 15.2 per cent over December, the North Central States 18.4 per cent and the Southern States 5.2 per cent. Productive operations in the Mountain and Pacific States appear to be on about the same level as in December.

Lumber and its products is the only industrial group not recording a materially increased rate of February operations over December, although this group did record increased February operations over January. The greatest increase in the rate of production since the opening of the year has been recorded by the rubber and its products industry, with February operations 41.8 per cent over December, followed by the automobile industry with a 39.7 per cent gain, stone, clay and glass 28.8 per cent, metal working plants 26.2 per cent, rolling mills and steel plants 21.1 per cent, leather and its products 20.7 per cent, chemical and allied products 18.5 per cent, textiles 13.6 per cent, food and kindred products 10.5 per cent, and paper and pulp 1.7 per cent. It is to be expected that materially increased production would be reported during January, February and March, but the rates of increase reported above are in most cases above that to be expected, based upon increases recorded in past years. It now seems probable that several industrial groups will hang up new records of production for the first quarter of the year.

# Business News and Market Conditions

## Trend of Sound Practice in Industry

*Survey Shows That More Companies Reporting a Decrease in Profits Reduced Prices Than Those Which Had an Increased Profit*

REDUCTION of manufacturing costs, the purchase of new machinery and an improvement in the quality of the product stand out as the three most important things which manufacturers have done to cope with competition. Following these as a close second, according to a published report of a survey of industry made by the Sherman Corporation of Boston, come product research, process research, market research, increased inventory turnover and a reduction of overhead cost. Of the concerns reporting profit increases 86 per cent said they had reduced the unit cost of manufacture. Concerns reporting profit decreases included only 64 per cent which said they had reduced unit cost to manufacture. Companies in the profit increase group included 63 per cent which said they had reduced their overhead, while 52 per cent of the profit decrease group reported overhead reductions. These figures are significant in showing the relation of profits to the reduction of overhead.

Sixty-one per cent of the concerns reporting profit increases increased volume of sales, while only 27 per cent of the companies showing decreased profits had increased their sales volume. Furthermore only 41 per cent of the profit increase group reduced selling price, while 64 per cent of the decreased profit group had cut selling price. This is regarded as especially significant, as "not getting a fair price" is regarded by many business executives as a key problem in manufacturing today. And the concerns reporting improved profit position reduced expense to sell two to one as compared with the concerns reporting profit decreases. A check of the most pressing current manufacturing problems, divided on a percentage basis, is as follows:

| | Per Cent |
|---|---|
| Sales | 35 |
| Production | 29 |
| Price | 21 |
| Style | 4 |
| Quality | 4 |
| Administration | 4 |
| Financing | 3 |
| | 100 |

The trend of sound practice obviously is toward reduction of unit manufacturing cost, maintenance of selling price, reduction of overhead, reduction of sales expense and, as a result of internal economy and efficiency, increase of sales volume. The book containing the report of the survey of industry is entitled "What Is Happening to Business." It also contains excerpts from interviews with representative business executives on the subject of the report.

The outstanding conclusions drawn, with the report as a basis, are given as follows:

1. The product itself is of primary importance. Its quality should not be impaired, but improved and kept to high standards. One way out for manufacturers is to develop merchandise of such quality that price-cutting tendencies can be met by getting into a class of business not dependent primarily on price. It is a day when an honest product is fundamental.

2. In manufacturing there can be no let-up in sound cost reductions. Increasing inventory turnover, getting greater value for the labor dollar, reduction of overhead and reducing time of manufacture are thoroughgoing economy programs which are vitally essential today in all lines of manufacture.

3. Much of the profit decline may be traced back to a hectic scrambling for a larger share of a market of certain fixed size and scope. If there is just so much market available, then cutting prices to get more of that market simply takes away from another manufacturer. Therefore, the necessity of developing new markets.

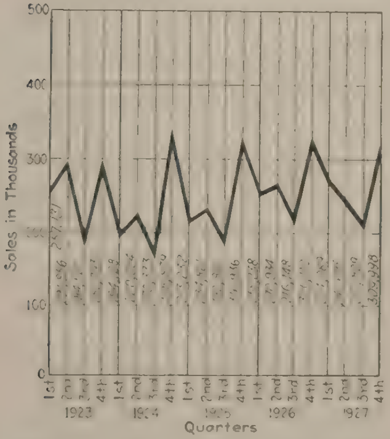
4. Research, a "competition in creation instead of on price," development of new products—these practices will open new markets and allow perhaps a better-balanced production in plants working at 40-50-60 per cent capacity.

5. Price maintenance, wherever possible, is vitally essential. "Price fixing" is out of the question. But the individual manufacturer who has a bottom price and conducts business solidly and courageously, even at a loss of certain volume, with the idea of keeping a semblance of soundness in his price situation, is rendering manufacturing industry a real service and laying the groundwork for improved profit position.

6. The "big pinch" in manufacturing business is selling expenses. Thorough analysis of sales with the purpose of reducing costs to sell is essential.

7. Consolidations and mergers on a basis of economical future operations, especially the reduction of selling and distribution expenses, and not solely on the "window dressing" of past earnings records, are inevitable.

### Vacuum-Cleaner Sales

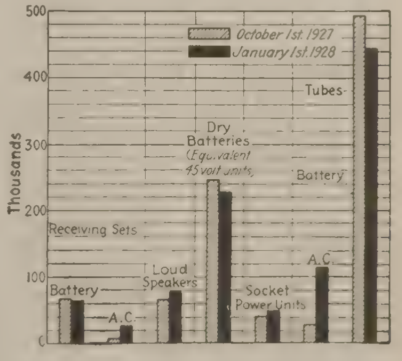


Vacuum-cleaner sales by quarters during 1923, 1924, 1925, 1926 and 1927. (Data supplied by Vacuum Cleaner Manufacturers' Association.)

## Building Industry Starts Co-operative Development

Representatives of about 31 of the most important interests in and allied with the building industry launched a national co-operative movement to provide clearing house functions to promote the rehabilitation of the existing homes in America and to create an enlarged and stabilized market for the building industry. The purpose of the movement is said to be to act as a clearing house for the building industry and allied industries or interests and to promote activities such as to advance standards of housing and living; to provide a broader and enlarged market, a more uniform monthly and yearly building activity and employment and a resultant high level of national prosperity; to promote home ownership; to encourage improvements in financing methods and facilities in all communities; to develop, collect and disseminate information regarding markets, and to encourage study and research in all important aspects of housing.

### Stocks in Hands of Radio Dealers



*Actual returns of approximately 25 per cent of dealers listed*

Compiled by the Electrical Equipment Division, Bureau of Foreign and Domestic Commerce, Washington, D. C., with the co-operation and assistance of the radio division, National Electrical Manufacturers' Association.

NOTE.—Radio business during 1927 approximated $500,000,000, according to a statement by R. A. Klock, chairman of the statistical committee, radio division, N.E.M.A.

# Market Conditions

STEADY trade is reported in the New England district, with the demand for small motors and industrial equipment at a good level. Negotiations for paper mill equipment are under way and street-lighting projects command attention. In the Eastern district sales are maintaining a good average. The call for prime movers shows an improvement, and a 60,000-kw. turbo-generator was purchased for St. Louis at a cost of $750,000. Orders for switching equipment totaled $310,000 and nearly $1,000,000 worth of wire and cable was bought by a New York utility company.

Healthy business is reported in the Southeast. A central-station company placed a large order for wire and several orders from textile mills are pending. In St. Louis a heavy demand for building materials was reported and an order for $71,000 worth of equipment was placed by a central-station company. Better business is indicated in the Middle West, but there is some apprehension regarding the bituminous coal situation. Industrial activity continues generally favorable. On the Pacific Coast industrial buying continues at a steady rate. The city of Seattle has awarded a contract for the Cedar Falls pipe line at a cost of nearly $250,000. Four carloads of pole line hardware were purchased by power companies.

## *Copper Demand Light—Price Stable*

The demand for copper has been light from domestic as well as foreign buyers. February copper statistics show heavy shipments during February. Lead is in normal demand after the heavy buying of last week. The zinc market continues to advance. A decrease in the price of tin attracted consumer buying.

NEW YORK METAL MARKET PRICES

| | Mar. 7, 1928 Cents per Pound | Mar. 14, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 14.125 | 13.825 |
| Lead, Am. S. & R. price | 6 | 6 |
| Antimony............ | 10¼ | 10⅜ |
| Nickel, ingot.......... | 35 | 35 |
| Zinc spots........... | 5.875 | 6 |
| Tin, Straits.......... | 51¼ | 50¼ |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper price March 14, 1928, 15¾ cents.

## *Buying in New England District at Steady Rate*

A steady demand for small motors and industrial equipment continued in the New England district. Small motor sales are well up in volume. Orders for a number of higher ratings from 50 hp. up and one of 600 hp. also is noted. Of interest was an order for a 3,150-kw. converter and increased activity in power control apparatus. Central-station supplies are in spotty demand, but pole line material is moving well. Some of the equipment for a short 33,000-volt line in southern New Hampshire was purchased and included about $10,000 worth of insulators. Negotiations for equipment for paper mills are under way.

Sales of contractors' supplies are more active. A number of motor pumping units were recently ordered and sales of arc-welding equipment are gaining as compared with those of last month. Among the major appliances, refrigerators are prominent, with commercial types rapidly gaining favor. Street lighting projects command attention. The Rhode Island Processing Company's plant recently destroyed by fire at a loss of $200,000 will be rebuilt. Authority for the carrying out of the Boston North Station plan for a large arena, new station and hotel has been granted. The Seth Thomas Clock Company, Thomaston, Conn., plans a four-story addition.

## *Sales Hold Good Average in Eastern District*

Good general demand for standard electrical equipment prevails in the Eastern district. A number of utilities are in the market for spring requirements and sizable commitments have been made. The call for prime movers shows improvement and inquiries indicate some desirable orders in this line at an early date. A central station at St. Louis has placed a contract for a 60,000-kw. generating unit with accessory equipment, to cost approximately $750,000. A utility at Keokuk, Iowa, is expected to place orders for several 2,000-kw. generating sets within a short time. A waterwheel manufacturer at York, Pa., has secured a contract for a unit for municipal service at Stoughton, Wis., the order for generating equipment going to a Minneapolis (Minn.) producer. The outlook for early increase in substation business is favorable. A central station in New Jersey has divided an order for switching equipment among three large manufacturers, the total approximating $310,000. The same interest also has purchased oil circuit breakers and auxiliary apparatus aggregating $100,000. A central station company in New York, in addition to the $320,000 worth of high-tension cable reported purchased last week, has ordered $670,000 worth of high-tension cable, $240,000 worth of rubber insulated cable and $60,000 worth of weatherproof wire and cable.

The call for industrial motors shows a temporary lag, following considerable business in larger-sized units in recent weeks. It is expected that there will be a resumption of the demand from iron and steel mills, paper mills and other active industries at an early date. A washing machine manufacturer in a northern New York city has placed a large order for fractional-horsepower units totaling $60,000.

Business in the Philadelphia district shows improvement. There is a better call for transmission line and substation equipment from utilities and early contracts are looked for. The United Gas Improvement Contracting Company recently placed an order for a 30,000-kw. turbo-generator with the Westinghouse Electric & Manufacturing Company and it will be built at the South Philadelphia works. The unit will be used for an installation at New Braunfels, Tex., and includes condensing apparatus.

Immediate construction operations are as follows: The Port of New York Authority, New York, is asking bids until March 26 for complete electrical equipment for the Elizabeth-Howland Hook bridge. The Skenandoa Rayon Corporation, Utica, N. Y., plans several plant units to cost $2,000,000. The Victor Plaster Company, Rochester, N. Y., plans a gypsum plaster mill at Victor, N. Y. The Corona Corporation, Jersey City, N. J., will build a five-story factory addition to cost $100,000. The Pennsylvania Power & Light Company will make improvements in transmission lines at Wilkes-Barre, Drums, Pa., and vicinity, rebuilding a considerable portion for heavier voltage. The Pennsylvania Water & Power Company, Holtwood, Pa., plans a hydro-electric development at Safe Harbor on the Susquehanna River. The Bureau of Supplies and Accounts, Navy Department, Washington, D. C., is asking bids until March 27 for three electric baking ovens for Newport News and Mare Island navy yards (Schedule 8674).

## *Healthy Business Reported in the Southeast*

The tone of electrical business in the Southeast is healthy and there is a considerable amount of business in prospect. A central-station company ordered 14 miles of bare stranded copper wire, 30,000 lb. of weatherproof copper and 10,000 lb. of bare copper wire. Another interesting power company order was for four 66,000-volt potential transformers and two 66,000-volt oil circuit breakers, while another company purchased creosoted pine poles amounting to $6,500. Orders for control batteries from central-station companies for the first two months of this year have been very good and considerably ahead of those for the same period of last year. Six electric industrial trucks have been placed in the New Orleans territory and one in Atlanta, and an order for 45 street trucks for a laundry company is pending.

A textile mill in Alabama ordered $20,000 worth of motors and transformers and a hosiery mill in Georgia ordered a 125-kva. generator with necessary engine and switchboard equipment. Bids have been asked for a 2,500-kw. turbine for the U. S. Government penitentiary and the engineering contract has been awarded on a new textile mill for construction in Arkansas. Several textile jobs in North Carolina are in the negotiation stage and will probably be closed this week. Municipalities continue their buying activities.

Construction projects are as follows: The Strowd-Holcombe Cotton Mills Company, Birmingham, Ala., plans an addition to cost $150,000. The Chatahoochie Sand & Gravel Company, Columbus, Ga., plans an electric-operated washing and screening plant to cost $200,000. The Proximity Manufacturing Company, Greensboro, N. C., plans an addition to its textile mill to cost $150,000. The Alabama Power Company, Birmingham, plans a transmission line about 50 miles long from its hydro-electric power development at Martin Dam. The Duke Power Company will build a 100,000-volt steel tower transmission line from the Lake James power plant to points in McDowell County. The Western Carolina Power Company will build a transmission line between Rutherfordton and Marion, N. C., and has acquired a site of 5 acres at Marion for a substation. The Bristol Gas & Electric Company plans a transmission line from Butler to Mountain City, Tenn.

## *Heavy Demand for Building Materials in St. Louis*

Business in the southwestern part of the St. Louis district is keeping up. An order for oil well pumping apparatus amounted to $8,500 and another for switches and circuit breakers amounted to $17,000. A central-station company purchased $71,000 worth of equipment. Small-sized motors and transformers sold in fair volume. A number of large buildings nearing completion has caused a good demand for conduit, wire and other electrical building materials. Manufacturers are figuring on several good-sized jobs.

Construction projects are as follows: Alexandria, La., plans an addition to its municipal power plant to cost $35,000. The Dixie Creamery, Inc., Shreveport, La., plans a new plant at Abbeville, La., to cost $100,000. The United States Cold Storage Company, Kansas City, Mo., plans improvements in cold storage and ice plants to cost $1,000,000. Marshall, Mo., plans extensions in its municipal power plant to cost $80,000. The Black River Hydro-electric Company, St. Louis, Mo., plans a hydro-electric generating plant at Poplar Bluff, Mo., to cost $3,000,000. The Empire Refineries, Inc., Tulsa, Okla., plans an industrial alcohol plant at Ponca City, Okla., to cost $300,000. The Magnolia Petroleum Company will extend its refining plant at Beaumont, Tex., to cost $200,000. The Gulf Coast Shell & Cement Company, Houston, Tex., plans a cement mill at Palacios, Tex., to cost $150,000. Cushing, Okla., St. Joseph, Mo., and Childress, Tex., plan installation of ornamental lighting systems.

## *Industrial Buying Steady on Pacific Coast*

Power company orders on the Pacific Coast have included four carloads of pole line hardware, $50,000 worth of distribution transformers for Tacoma and $3,000 worth of poles for Modesto. The San Joaquin Light & Power Corporation is in the market for 2,500 untreated poles, 7 in., 35 ft., for Fresno delivery, a potential order of close to $20,000. Projected building construction includes a $400,000 bank for Bakersfield, a $300,000 apple storage warehouse for Watsonville, a $600,000 church, a $300,000 marble yard and factory and a $500,000 stock exchange for San Francisco and a $500,000 theater and a $3,000,000 department store for Oakland. Overseas business included a 200-hp. synchronous motor and accessories, valued at $3,500, for a Hawaiian plantation and an electrical dredge for Malaya amounting to $30,000. Other varied industrial orders include two 500-hp. motors with switchboard and accessories amounting to $45,000 for an ice company and a 250-hp. induction motor and special control valued at $6,000 for a Nevada mining company.

Numerous but scattered sales of motors, ranging from 100 hp. down, were made to lumber mills, pulp and paper plants, irrigation and orchards, machine shops and other industrial plants by Seattle jobbers. Big orders for electrical equipment for several proposed pulp and paper mills are still in abeyance. The city of Seattle awarded a contract for the Cedar Falls pipe line for $242,024. The city of Seattle also awarded contracts for 32 indoor type and two outdoor type regulators for $42,129 to the General Electric Company, and called for bids for a fourteen-thousand-dollar switchboard and about $3,000 worth of outdoor type reactors. The Great Northern Power Company, Seattle, is planning an expenditure of $10,000,000 for enlargement of its hydro-electric plant at Gold Bar. Transmission line extensions are planned by the Grays Harbor Railway & Light Company, the Washington Water Power Company and the Puget Sound Power & Light Company in various districts.

Construction projects are as follows: The San Joaquin Light & Power Corporation, Fresno, Calif., plans a substation on Ashlan Avenue to cost $80,000. The Western Oil & Refining Company, Los Angeles, will make extensions in its refining plant at Wilmington to cost $1,000,000. The Western Oxygen Company, Los Angeles, plans a new plant at Sacramento, Calif., to cost $100,000. The United States Indian Irrigation Service, Los Angeles, will receive bids until March 28 for boilers, etc. The Alexander Industries, Inc., plans a new plant at Colorado Springs, Colo., to cost $100,000. The Longview Fibre Company, Longview, Wash., plans a new power plant to cost $150,000. The Great Western Sugar Company, Denver, Colo., contemplates a beet sugar refining plant in the vicinity of Powell, Wyo., to cost $150,000. Los Angeles, Los Banos, Santa Maria and Modesto, Calif., and Pendleton, Ore., plan ornamental lighting systems.

## *Better Business in View in Middle West*

The slight recession in business noticeable during February in the Middle West is apparently halted and better business is in view as indicated by steel mill operations, car loadings, automobile sales and retail trade. There is still a fair amount of unemployment. Some apprehension is felt regarding the bituminous coal situation as a tie-up of operations will undoubtedly affect general business in the coal regions. Industrial activity continues generally favorable with considerable construction work in view. Building activity in the Chicago suburban district increased 8 per cent. Manufacturers of pole line hardware report good business, one manufacturer operating 24 hours per day. Maintenance purchasing is quite large, adding materially to the general volume of business.

Construction projects are as follows: The Arkell Safety Bag Company, New York, plans a new branch plant at Chicago, to cost $100,000. The United Felt Company, Chicago, plans a new mill to cost $150,000. The Illinois Northern Utilities Company plans a steam power plant at DeKalb, Ill. The National Plate Glass Company, Ottawa, Ill., plans an addition to its local plant to cost $175,000. The Solem Machine Company, Rockford, Ill., plans an addition to cost $125,000. Evansville, Ind., is asking bids, until March 29, for generators, steam engines, switchboard and auxiliary equipment. The Major Brothers Packing Company, Mishawaka, Ind., plans a three-story plant to cost $350,000. Hawarden, Iowa, will build an addition to its municipal power station. Anderson, Ind., is taking bids on a 12,500-kva. turbo-generator, condensing equipment and auxiliaries. Charles Brossman is consulting engineer, 1010 Chamber of Commerce, Indianapolis, Ind. Swift & Company, Chicago, plans a meat-packing plant at North Platte, Neb., to cost $150,000. The Beet Growers' Association of North Platte Valley, Scottsbluff, Neb., plans a beet sugar refining plant to cost $115,000. The Northwestern Public Service Company, Aberdeen, S. D., will make extensions in its power plant to cost $250,000. The Lakeshire Cheese Company, Loyal, Wis., plans a plant to cost $100,000. The Houghton County Electric Light Company plans a transmission line from Houghton to Chassell, Mich. The Cleveland Electric Illuminating Company, Cleveland, plans a 58-mile steel tower transmission line to cost $1,800,000.

# Activities of the Trade

## Cutter Company Now Known as I-T-E Circuit Breaker

The Cutter Electrical & Manufacturing Company of Philadelphia, manufacturer of "I-T-E" circuit breakers and "U-Re-Lites" for 40 years, has changed its name to the I-T-E Circuit Breaker Company. Philip C. Gunion, sales manager, said that the primary reason for changing the name was that the company was constantly being confused with two other electrical manufacturers of similar name, one of which is owned by a competitive organization. There has been no Mr. Cutter connected with the company for more than 25 years. The name of the product, the I-T-E circuit breaker, was used in giving the company a descriptive name that cannot be confused with the name of any other company. The policies, personnel and products of the I-T-E Circuit Breaker Company are identical with those of the old company.

## Sundh Electric Appoints New Officers

Following the resignation of Louis Larsen, general manager, the Sundh Electric Company of Newark, N. J., announces the appointment of Edward Quimby as general manager, and H. J. Kaufman as general sales manager. Mr. Kaufman has been with the company for the last eighteen years, serving recently as supervising sales manager with headquarters at Chicago. The company states that no other changes were made in the organization.

## Refrigerator Sales Show Promise in 1928

Refrigerator distributors of the General Electric Company at a two-day meeting at Cleveland voiced indications of a very good year for 1928. It was brought out that the barometer of public interest for electric refrigeration had gone up. "Although the country has absorbed other products, so far refrigeration has not been fully exploited," said P. B. Zimmerman, sales manager of the electric refrigeration department, in addressing the distributors. "In 1927 387,000 electric refrigerators were sold and it is estimated that the 1928 production will not be less than 500,000. Only 4.3 per cent of the total number of wired homes in the country are equipped with electric refrigeration. The year 1928 will be a good one for the industry as a whole and especially for the General Electric refrigerator. In every case where distributors are leading the field in their territory, their business volume is in direct relation to activity. This is very significant," Mr. Zimmerman explained. The two-day meeting was called to discuss distribution problems in sections of the country and to exchange ideas on proper organization of dealers.

Three hundred members of the Metropolitan district sales force and General Electric executives from Cleveland and Schenectady also met recently at a breakfast given by Rex Cole, Metropolitan distributor, at the Hotel Commodore, New York. Several men spoke on the growth of electric refrigeration. On Friday of this week a special train carried the guests of Mr. Cole to Schenectady to visit the laboratories and plants of the General Electric Company.

## Westinghouse Gets Order for Circuit Breakers

An order for switching equipment has been placed by the United Electric Light & Power Company of New York with the Westinghouse Electric & Manufacturing Company. This contract includes eighteen 5,000-amp., three-phase, horizontally segregated phase oil circuit breakers, disconnecting switches and associated details. The breakers have an interrupting capacity of 1,500,000 kva. at 15,000 volts. This breaker order is a duplicate of a previous one and makes a total of 36 such breakers now on order for the United company. The contract also covers 100 500-amp. automatic network protectors, which will be applied to feed three-phase, four-wire, 120-208-volt secondary networks.

Schweitzer & Conrad, Inc., 4421 Ravenswood Avenue, Chicago, manufacturer of high-voltage protective and switching equipment, announces the appointment of J. Leo Scanlon as New York City correspondent with office at Room 492, 50 Church Street.

The Mansfield Sheet & Tin Plate Company, Mansfield, Ohio, manufacturer of electrical sheets, has consolidated with the Ashtabula Steel Sheet Company, the Waddell Steel Company, the Thomas Steel Company, the Falcon Steel Company and the Empire Steel Company of Cleveland. The new organization will be known as the Empire Steel Corporation. The manufacture of electrical sheets will be continued at Mansfield without change under the direction of W. J. Wooldridge, as heretofore. The Empire Steel Corporation will specialize on enameling furniture, and stove sheets, light grade auto body sheets and its complete line of silicon-alloy electrical sheets.

The Condit Electrical Manufacturing Corporation, Boston, manufacturer of circuit breakers and power switchboards, announces the appointment of Harris & Butler, Real Estate Trust Building, Philadelphia, as sales representatives for the eastern Pennsylvania territory, including Delaware and southern New Jersey. The western Pennsylvania region, including West Virginia, Belmont and Jefferson Counties, Ohio, and the southern portion of Columbiana County, in Ohio, has been placed in charge of the E. S. Stickle Company, Union Trust Building, Pittsburg.

The Belden Manufacturing Company, 23d Street and Western Avenue, Chicago, manufacturer of insulated wires and cables, announces the removal of its office from 399 Market Street, Newark, N. J., to 39 Cortlandt Street, New York City. S. C. Schenck is Eastern manager.

The Electro-Nite Carbon Company, 306 North Fourth Street, Philadelphia, manufacturer of carbon brushes, announces that its Michigan office is now in charge of A. G. McMann and is located at 307 Basso Building, 7338 Woodward Avenue, Detroit.

The Electric Machinery Manufacturing Company, Minneapolis, manufacturer of synchronous motors and vertical alternators, announces the appointment of L. Brandenburger, 149 West Second Street, South, Salt Lake City, Utah, as its representative. R. R. Poppleton, Inc., 35 First Street, Portland, Ore., and 2963 First Avenue South, Seattle, Wash., also was appointed representative for Portland and Seattle.

Earle V. Hennecke, Inc., 247 Park Avenue, New York City, has been organized by E. V. Hennecke, formerly vice-president and general manager of the Moto Meter Company, Inc., Long Island. The company will furnish sales and advertising counsel to manufacturers of automotive, electrical and radio products, and also will act as a sales organization handling the complete distribution throughout the world for several large manufacturers.

The Graybar Electric Company, Graybar Building, Lexington Avenue and 43d Street, New York City, announces that J. A. Mayer has been appointed Oklahoma manager, with headquarters at Oklahoma City, and R. W. Conrad has been appointed sales manager at Tulsa.

The Allis-Chalmers Manufacturing Company, Milwaukee, announces the purchase of the Monarch Tractor Corporation of Springfield, Ill., manufacturer of crawler or tank type tractors. The purchase of the Monarch line now marks the entrance of the company into the industrial tractor field. The Monarch line will continue to be built at the Springfield plant.

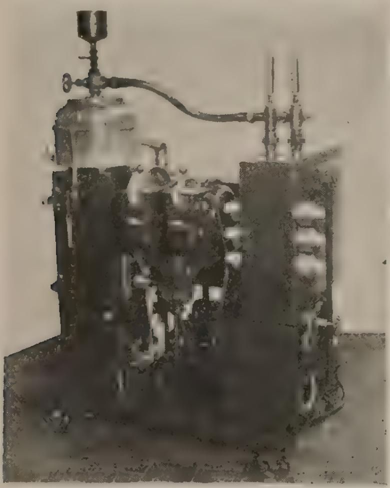
The Gurney Elevator Company, Inc., 1207 Race Street, Philadelphia, announces that Unit Rasin will have charge of sales in the Philadelphia district.

Combustioneer, Inc., 570 West Randolph Street, Chicago, has been organized by some of the officials formerly interested in the Iron Fireman Corporation of Chicago. The company is producing a new automatic coal-burning device for boilers rated up to 200 hp.

# New Equipment Available

## Oil Dehydrator and Filter

A new type of centrifugal separator and clarifier has been placed on the market by the "Positive" machinery division of the National Acme Company, Cleveland. The construction of the bowl and cylinders is such that it permits the use of a filter cylinder and filtering mediums, such as felt, linen, paper, etc. The company states that this combined centrifuging and filtering action not only dehydrates the oil but also removes the finest particles of suspended carbon. The separator is furnished in either stationary or portable types. Pumping, heating and cooling equipment are optional, but the company also is offering a portable separator with pumping equipment and immersion heaters mounted on a truck. The portable equipment is shown in the illustration.



*Portable type hydrator and filter with pump and immersion heaters mounted on a truck*

## Unit Pulverizer

Development made on different sizes of Riley "Atrita" unit pulverizers, made by the Riley Stoker Corporation, Worcester, Mass., are said by the company to give greater reliability, smoother performance and decidedly lower maintenance. The majority of these developments have been in the design and construction of the pulverizing elements. Originally the pulverizing elements consisted of small oval-shaped pegs. The next step in the development was the use of larger round pegs. This increase in the size of the pegs the manufacturer claims increased the life over the original design several times. With the peg type of construction it was necessary to install wearing plates on the rotor to take care of any tendency of the rotor to wear. The present construction consists of small cast segments which are installed on the rotor. The face of these castings acts as the wearing plate. The peg section of the unit casting is many times larger than the 2½-in. pegs previously used. Greater fineness of pulverization also has been obtained, as well as smoother operation.

The greatest feature of the new construction pointed out by the manufacturer is the low maintenance which has resulted from its use. The life of the pulverizing elements has been increased from four to seven times that of the peg construction. The method of supplying hot air to the unit pulverizer has also been redesigned to assure more effective use of hot air, which is particularly necessary when coal with a high moisture content is being used. The coils used in the magnetic separator have been entirely inclosed.

## Starter for Small Motors

A new motor starter with a maximum rating of 7½ hp. has been announced by the Westinghouse Electric & Manufacturing Company. The addition of this "Linestarter" now provides the company with a complete line of full voltage starting devices ranging from 1 to 75 hp. The starter comes equipped with hand reset of the thermal overload relay, but if automatic reset is desired the hand reset lever can readily be removed and an automatic reset obtained. The approximate dimensions of the dust-proof inclosing cabinet are 8½ in. wide, 12½ in. high and 5¾ in. deep and the approximate shipping weight is 15 lb.

## Elevator Control Devices

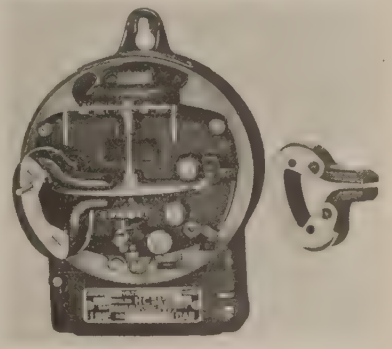
Three new control devices for elevator service, a limit switch, a reverse phase relay and a car switch, have been placed on the market by the General Electric Company. The limit switch is particularly designed for hatch mounting. It is suitable for emergency and overtravel limit protection on high-speed elevators and also may be used for normal limit protection on two-speed elevators, one limit switch being used for each speed. This limit switch is manufactured in three forms, as follows: Single-pole, double-break, normally closed; double-pole, double-break, normally closed, and single-pole, double-break, normally open.

The reverse phase relay is particularly designed for reverse and open-phase protection of elevator motors, although it is applicable to other types of service where the same protection is required. The car switch is designed for use with rheostatic control of either the alternating- or direct-current type and can be used either on single-speed or adjustable-speed motors. Two-point control in either direction of travel is provided.

## Watt-Hour Meter

The Sangamo type HC watt-hour meter that is temperature compensated on inductive and non-inductive load has been announced by the Sangamo Electric Company, Springfield, Ill. The company states that the improved performance of the type HC meter has been obtained without any fundamental change in the mechanical or electrical design of the type H, which was brought out in 1914. Such important parts as the upper and lower bearings, the full load and light load adjustments, as well as many others, are interchangeable between the type H and the type HC.

The outstanding changes and improvements incorporated in the type HC are stated by the manufacturer to be: (1) Complete temperature compensation on both inductive and non-inductive load. No appreciable variation in accuracy, at any power factor, from 20 deg. F. to 120 deg. F. (2) Straight line accuracy up to 300 per cent load. (3) Decrease in speed of 60-cycle meter so that both 25 to 60-cycle type HC meters have the same constant; this being 1,200 watt seconds for the 5-amp., 110-volt meter. (4) Reversal of direction of rotation (for purposes of standardization). Mechanical improvements also have been made.



*The dowel pins for the permanent magnet serve as thermal-responsive shunts*

Temperature compensation on non-inductive load is accomplished by thermal-responsive magnetic shunts in the permanent magnet system and on inductive load by use of a thermal-responsive magnetic shunt in the pole face of the potential magnet. At present the type HC is available only in capacities up to and including 25 amp., two and three wire, 60-cycle single-phase. Later, a complete line will be available at all frequencies.

Flashing Beacon.—A new single-color, one-way flashing beacon especially adapted for mounting at bridge entrances, approaches to railroad crossings, dangerous curves in highways and busy intersections has been developed by the General Electric Company. This device may be suspended by means of a hanger or mounted on a pipe. It consists of a standard reflector-type door assembly complete fastened to a casting containing the flashing mechanism.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued Feb. 21, 1928)

1,660,084. Electrical Control System; E. R. Morton, New York, N. Y. App. filed Nov. 19, 1924. For controlling the frequency of wave generating devices.

1,660,093. Inclosing System for Electric Service Appliances; J. Sachs, Hartford, Conn. App. filed May 6, 1926. Meter service switch.

1,660,147. Electrolytic Gas-Generating System; W. G. Allan, Toronto, Ont., Can. App. filed Oct. 1, 1920.

1,660,150. Method of Volatilizing and Oxidizing Minerals; B. G. Cobb, Toronto, Ont., Can. App. filed April 6, 1921.

1,660,159. Production of Alloys of the Platinum Group; E. Haagn, Hanau-on-the-Main, Germany. App. filed Feb. 9, 1926.

1,660,161. Light-Dimmer Rheostat; E. H. Hansen, Metuchen, N. J. App. filed Nov. 2, 1923.

1,660,180. Combined Cross-Connecting Switch and Coupler for Electrical and Auxiliary Air Lines; H. E. Van Dorn, Chicago, Ill. App. filed April 19, 1922.

1,660,191. Current Regulating Means for Electric Induction Furnaces; C. B. Foley, Fort Wayne, Ind. App. filed March 23, 1922.

1,660,197. Electrical Relay; H. O. Holte, deceased, late of Pittsburgh, Pa. Orig. app. filed Sept. 9, 1924. Comprising a movable member arranged to be vibrated when alternating currents are supplied to the relay.

1,660,209. Electric Furnace; E. C. Sasnett, Washington, D. C. App. filed Sept. 24, 1919. Crucible induction furnace.

1,660,214. High-Tension Current Transformers; F. Ahrberg, Berlin-Halensee, G. Keinath, Berlin-Charlottenburg, and K. Schrader, Berlin-Halensee, Germany. App. filed Dec. 9, 1924.

1,660,218. Means of Heating Inclosures Electrically; C. L. Burgher, New York, N. Y. App. filed Oct. 27, 1925.

1,660,229. Storage Battery; P. Mallon, Paris, France. App. filed Dec. 16, 1927.

1,660,246. Process of Welding Cast Iron; H. V. Wille, Philadelphia, Pa. App. filed April 14, 1921.

1,660,256. Automatic Switch; J. T. Cowley, Syracuse, N. Y. App. filed Jan. 7, 1926. Particularly for use with refrigerating machines for controlling the motor in accordance with the temperature of the refrigerating chamber.

1,660,264. Method of Making Storage Batteries; E. A. Garlock, Baltimore, Md. App. filed July 15, 1924.

1,660,279. Separable Plug; S. R. Swenson, South Orange, N. J. App. filed Feb. 20, 1922.

1,660,285. Multiplier; E. F. Weston, Newark, N. J. App. filed Dec. 11, 1925. For a small indicating voltmeter.

1,660,290. Electrical Receptacle and Attachment; R. B. Benjamin, Chicago, Ill. App. filed July 14, 1920.

(Issued Feb. 28, 1928)

Reissue 16,892. Magnetic Motor; J. G. Ruckelshaus, Newark, N. J. App. filed June 11, 1926. For phonograph turntable.

1,660,317. Stand Lamp Construction; R. B. Benjamin, Chicago, Ill. App. filed June 5, 1924.

1,660,322. Voltage Regulator with Thermostatic Compensator; A. F. Brotz, Kohler, Wis. App. filed June 12, 1924.

1,660,390. Elevator Control Switch; M. B. McLauthlin, Malden, Mass. App. filed Sept. 17, 1921.

1,660,397. Battery Charging System; H. W. Sayles, Peoria, Ill. App. filed May 15, 1922.

1,660,399. Circuit Controller; W. C. Stevens, Milwaukee, Wis. App. filed July 26, 1920. For motors.

1,660,400. Exterior Operating Mechanism for Inclosed Circuit Controlling Devices; W. C. Stevens, Milwaukee, Wis. App. filed Nov. 8, 1920.

1,660,405. High Frequency Measuring System; H. A. Affel, Maplewood, N. J. App. filed Nov. 21, 1924.

1,660,422. Multiple Socket and Plug Device; B. P. McKinley, New York, N. Y. App. filed July 18, 1923.

1,660,425. Electric Butt Welding; T. E. Murray, Jr., Brooklyn, N. Y. App. filed Sept. 10, 1924.

1,660,491. Method of Welding; J. A. Leeper, Wilkinsburg, Pa. App. filed Aug. 31, 1925.

1,660,498. Electric Grounding Connection; W. H. Vibber, New London, Conn. App. filed Feb. 6, 1925. Ground connection for a water pipe.

1,660,499. Conduit Grounding Bushing; W. H. Vibber, New London, Conn. App. filed April 3, 1925.

1,660,504. Pyrometer; A. A. Grubb, Mansfield, Ohio. App. filed Aug. 6, 1925.

1,660,518. Electric Pad; T. H. McComsey, Los Angeles, Calif. App. filed April 6, 1926.

1,660,534. Safety Lamp for Mines; H. Takata, Tokyo, Japan. App. filed Sept. 15, 1925.

1,660,548. Electrical Fixture; W. B. Crowell, New York, N. Y. App. filed May 3, 1926. Such as push button boxes; means for mounting.

1,660,556. Detachable Terminal Connection for Electric Stove Elements; J. McC. Gunn, London, Ont., Can. App. filed July 14, 1925.

1,660,562. Trolley Wire Holder for Electric Tramways and Other Railways; A. Linde, Muckenberg, Nieder-Lausitz, Germany. App. filed Sept. 3, 1926.

1,660,620. Brake; G. W. Lautrup, Yonkers, N. Y. App. filed March 18, 1926. Multiple shoe braking mechanism for elevator hoisting machines.

1,660,649, 1,660,650. Seal; R. D. Mailey, East Orange, N. J. Apps. filed Oct. 16, 1923 and June 16, 1925. In electric apparatus a seal between lead-ins and vitreous walls through which such lead-ins pass comprising fused silver chloride.

1,660,746. Motor-Traffic Signal; J. T. Dye, New York, N. Y. App. filed Sept. 14, 1922.

1,660,784. Resistance Element for Electric Irons and the Like; H. Blanksten, Chicago, Ill. App. filed May 8, 1922.

1,660,787. Electric Water Heater; A. Favale, Detroit, Mich. App. filed Dec. 8, 1926.

1,660,794. Light-Therapy Appliance; W. Hudson, Milton, Wis. App. filed April 11, 1927.

1,660,805. Method of and Apparatus for Electrobrazing; H. E. Moineau, Marlboro, Mass. App. filed Feb. 24, 1926.

1,660,807. Binding Post; O. B. Norgren, Chicago, Ill. App. filed May 28, 1925.

1,660,815. Pole Cable Terminal; L. M. Persons, Chicago, Ill. App. filed June 18, 1926.

1,660,827. Electrical Connecter; F. A. Anderson, Milton, Wis. App. filed Dec. 22, 1921.

1,660,828. Electric Fuse; R. M. Bird, Charlottesville, Va. App. filed Dec. 1, 1922.

1,660,863. Connecter Socket; O. A. Colby, Irwin, Pa. App. filed Jan. 23, 1923.

1,660,865. Switch Structure; R. C. Deale, Plainfield, N. J. App. filed July 16, 1925. For controlling the operation of planers and similar machine tools.

1,660,869. Wax Eliminator; L. V. Feike and J. R. Payton, Des Moines, Ia. App. filed Feb. 3, 1926. For use with a dentist's mold.

1,660,873. Trolley Conductor Support; B. Hines, Wilkinsburg, and H. N. Richards, Pittsburgh, Pa. App. filed Feb. 14, 1927.

1,660,874. Circuit Interrupter; C. H. Hodgins, Pittsburgh. Pa. App. filed July 15, 1920. Quick-acting type.

1,660,900. Relay; R. J. Wensley, Edgewood Park, Pa. App. filed April 16, 1918. For controlling rotary or synchronous converters.

1,660,920. Soldering Iron; H. J. Fanger, Oakland, Calif. App. filed Aug. 23, 1926.

1,660,921. Recording Galvanometer; R. Fischer, Frankfort-on-the-Main, Germany, App. filed May 4, 1921.

1,660,956. Coin Operated Rotary Time Switch; L. C. Eppler, Groton, N. Y. App. filed March 19, 1923.

1,660,965. Protective System; W. L. Hartzell, Chicago, Ill. App. filed Aug. 25, 1922. For the prevention of abnormal operation of polyphase induction motors and the like.

1,660,979. Current Control Device; W. J. Thayer, Westfield, N. J. App. filed June 30, 1926.

1,661,020, 1,661,021, 1,661,022. Elevator-Control System; E. B. Thurston, Toledo, Ohio. Apps. filed Dec. 10, 1921, May 8, 1922, and Sept. 28, 1923.

1,661,026. Electric Furnace; A. J. Asch, New York, N. Y. App. filed Feb. 4, 1927. As used in dentistry.

1,661,030. Weed Destroyer; W. E. Burt, Yuba, Wis. App. filed June 28, 1926.

1,661,054. Low Water Alarm for Boilers; F. E. Snyder and J. P. von Giesen, Bronx, N. Y. App. filed Dec. 27, 1926.

# New Trade Literature

CHAIN DRIVES. — The Morse Chain Company, Ithaca, N. Y., has issued a catalog covering the Morse silent chain drives. It describes the design and construction of these drives and contains price lists and reference tables. Illustrations showing the various applications of the drives to power transmission requirements in almost every industry are included. The catalog is virtually a handbook on silent chain drives.

SWITCHES AND PUSH BUTTONS.—The Clark Controller Company, Cleveland, is distributing bulletins 105-B and 110, describing and illustrating the Clark "Three C" starting switches for alternating-current motors, and the Clark "Three C" push buttons.

ELECTRIC RANGES AND WATER HEATERS. — A catalog issued by the Walker & Pratt Manufacturing Company, 31 Union Street, Boston, describes and illustrates the various types of "Crawford" electric ranges, water heaters and other "Crawford" electrics. Wiring diagrams and installation suggestions are also included. This catalog is being distributed by the Graybar Electric Company.

SWITCHES.—A series of new catalog sheets to supersede pages now in the company's catalog No. 17 are being distributed by the Trumbull-Vanderpoel Electric Manufacturing Company, Inc., Bantam, Conn., describing and illustrating its current breakers, its main line type "Mason" safety switches and type C inclosed switches.

LINE CONSTRUCTION.—A catalog issued by the Hoosier Engineering Company, 100 West Monroe Street, Chicago, entitled "Cutting the Cost of Transmission Line Construction" covers its overhead and underground line construction. An illustration and description of several typical installations are given.

ARC WELDING SUPPLIES.—A booklet issued by the Lincoln Electric Company, Cleveland, covers its line of welding supplies, including cables, glass, shields, welding electrode, rods, aprons, gloves, brushes, electrode holders, etc.

COUPLINGS AND EDGEWOUND RESISTORS. — Bulletins 103-A and 104-B issued by the Clark Controller Company, Cleveland, describes and illustrate the Clark "Three C" flexible couplings for operation in connection with motors driving reversing mill tables, pumps, compressors, cupola blowers, screwdowns, etc., and the Clark "Three C" edgewound resistors designed to suit all requirements of space or service. The bulletins contain tables of sizes, ratings, etc.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Toulouse, France (No. 30,044), for electric clocks and electric measuring instruments.

An agency is desired in Amsterdam, Netherland (No. 30,043), for household electrical appliances and wiring supplies.

Purchase and agency are desired in Vienna, Austria (No. 30,076), for household electrical appliances.

An agency is desired in Riga, Latvia (No. 30,049), for insulating materials.

Purchase is desired in Andheri, India (No. 30,096), of electric marble-polishing machines.

An agency is desired in Vienna, Austria (No. 39,045), for electric refrigerators.

Purchase is desired in Agua Prieta, Mexico (No. 30,094), of street lighting system equipment.

Purchase is desired in Ciudad Juarez, Mexico (No. 30,075), of complete ten-wire telephone line.

Purchase is desired in Palermo, Italy (No. 30,078), of tungsten lamp filaments.

Pawel Bitschan, Kredytowa 18, Warsaw, Poland, is interested in obtaining catalogs from American electric display sign manufacturers who desire to enter the Polish market.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for
the Use of All Interested in Analyzing the
Trend of the Electrical Business

## Growth in All Parts of the Union

THE best guide to the future is a study of the past. During the five years ended with 1927 sales of electrical energy by public utility plants in the United States increased at an average rate of $140,000,000 a year; from about $1,072,000,000 in 1922 to $1,783,000,000 in 1927. The energy output during the same period increased from 43,560,000,000 to 75,116,000,000 kw.-hr., or at a rate close to 6,300,000,000 kw.-hr. a year. On the whole the industry has thus expanded 73 per cent in output and 65 per cent in revenue in half a decade.

Such rapid growth is not unknown in recent business history, but it has in the main been confined to relatively new industries that are presumably in their period of most vigorous expansion, having passed through the initial developmental stage and having still far to go before their market approaches saturation. The electric light and power industry, however, is not a newcomer. Yet its gain since 1922, both in revenue and in energy output, was substantially equal to the whole magnitude in 1919. And 1919 is not so long ago. It may be safely assumed, therefore, that progress in the immediate future at least will continue at the same average rate as heretofore, with the attendant business in electrical goods of all sorts for added residential and industrial applications of power. Add also the necessary replacements of existing materials as they wear out or become obsolete, as well as all the requisite new construction in the power industry itself. The latter is meeting the increasing demands by the net addition of 2,000,000 kva. annually, aside from replacements. Nothing short of a nation-wide catastrophe, or radical interference with normal progress, is likely to affect so well established a trend, except very gradually, and any such catastrophe or interference would necessarily affect with equal severity our entire industrial equilibrium.

Further details are shown by analysis of regional figures. For this purpose the country has been divided into five major sections. Most rapid growth has occurred in the South Central States, particularly in the new industrial Southeast and in the farther Southwest. In that part of the country the output has doubled in the four years since 1923, rising in 1927 to 6,714,000,000 kw.-hr. Revenue, which exceeded $174,000,000 in 1927, fell short of doubling in four years, but more than doubled in five years. In 1927 the energy output exceeded that of 1922 by 138 per cent.

The next highest rate of growth in output occurred in the Atlantic States and amounted to 72 per cent in five years. Next comes the North Central region, with 69 per cent in the same period, and then the Western States with 63 per cent. Notwithstanding the difficulties that stand in the way of rapid load building in an old-established community, with industries long accustomed to the use of their own source of power, the increase in New England was 58 per cent. Were it not overshadowed by the still more rapid development elsewhere in the country this continued advance at 12 per cent annually would be considered remarkable. In many other lines of activity it would be extraordinary. It surely is evidence of constant growth in New England's industrial mechanism as a whole, for electricity constitutes the warp of the industrial fabric. Its increased use signifies more production. And what is here said of New England applies similarly, and in proportionate measure, to the changing electrical consumption elsewhere.

In actual output during 1927 the regional totals, in millions of kilowatt-hours, were: Atlantic, 27,086; North Central, 22,607; Mountain and Pacific, 13,727; South Central, 6,713; New England, 4,983.

In the several regions the revenue figures show the same changes as those for energy generated, except that the movements are generally a little smaller, as might be anticipated in view of the gradual decrease in the price of energy.

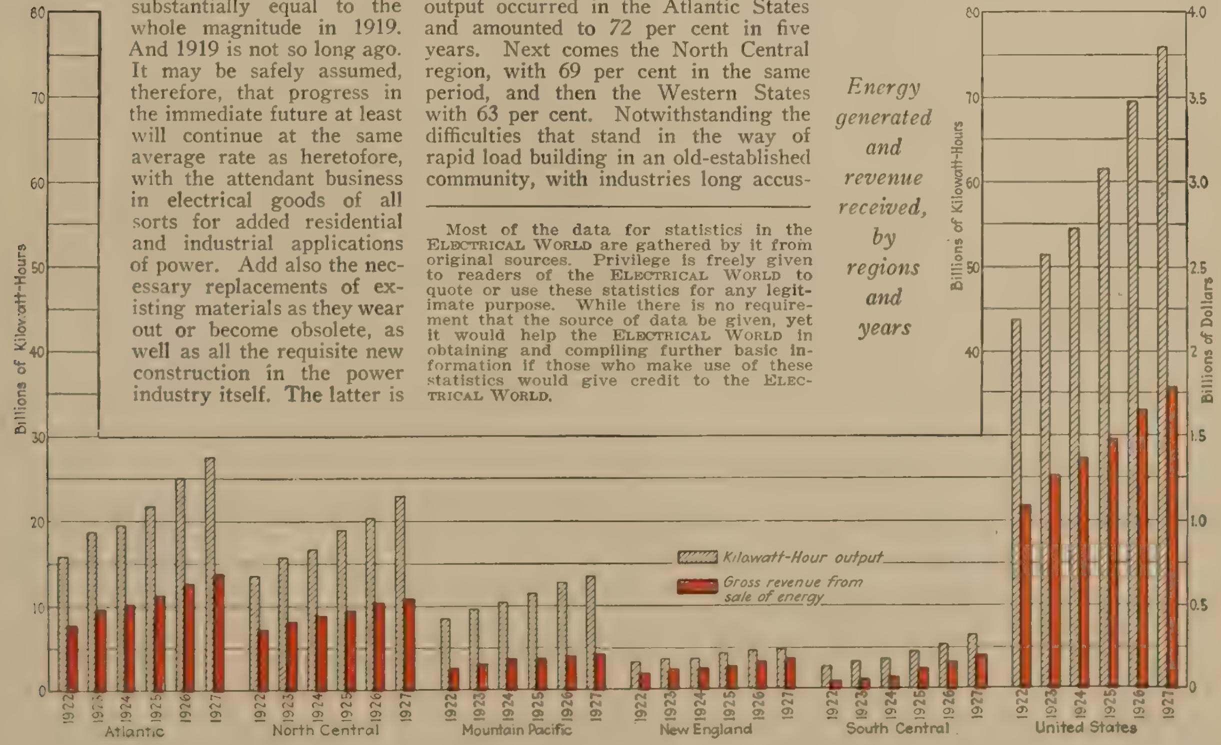
Most of the data for statistics in the ELECTRICAL WORLD are gathered by it from original sources. Privilege is freely given to readers of the ELECTRICAL WORLD to quote or use these statistics for any legitimate purpose. While there is no requirement that the source of data be given, yet it would help the ELECTRICAL WORLD in obtaining and compiling further basic information if those who make use of these statistics would give credit to the ELECTRICAL WORLD.



*Energy generated and revenue received, by regions and years*

*Atlantic States have maximum output, South Central the fastest growth*

# Materially Increased Industrial Operations in Southern States

REPORTS on the consumption of electrical energy by the manufacturing plants operating in the Southern States indicate that the first two months of the year witnessed a slightly more than normal increase in the rate of industrial production in this section. February activity was about 11.5 per cent over January and 10.4 per cent over December. Compared with the same month last year the February activities showed an increase of about 9.4 per cent. An upward trend in the rate of production is to be expected at this season of the year, but the rate of increase witnessed from December through February was the greatest recorded in any year since 1923, which is the first year for which data on electrical energy consumption by manufacturing companies was collected.

*Indexes of Productive Activity in the Southern States*
(All Figures Adjusted for Number of Working Days)

| | Feb., 1928 | Jan., 1928 | Feb., 1927 | Average for Full Year 1927 | Average for Full Year, 1926 |
|---|---|---|---|---|---|
| All industries | 141.8 | 127.2 | 129.6 | 127.6 | 115.9 |
| Fertilizers | 121.7 | 115.0 | 224.0 | 109.5 | 184.3 |
| Metal industries group | 128.7 | 119.1 | 152.0 | 125.9 | 129.5 |
| Stone, clay and glass | 204.0 | 161.8 | 154.0 | 156.5 | 119.7 |
| Textiles | 145.7 | 132.6 | 149.2 | 146.0 | 117.9 |
| Paper and pulp | 136.5 | 135.3 | 127 5 | 126.9 | 118.3 |
| Lumber | 136.2 | 119.0 | 83.9 | 101.8 | 101.0 |
| Food | 129.1 | 125.1 | ..... | ..... | ..... |

These favorable conditions, however, have not been experienced by all of the basic industries of the Southern States. The textile plants, the most important industry of the section, reported a decrease in operations since December of about 4 per cent, and operations during February about 2.4 per cent under February of last year. This is the first time since 1924 that the February rate of textile activities has been under that of the same month in the year previous. On the other hand, the food, metal working, lumber, paper and pulp and the stone, clay and glass industrial groups all reported materially increased operations over the month of December.

## *The San Francisquito Disaster*

JUST what caused the St. Francis Dam to burst in the night of March 12 and to unloose the deluge which brought swift death and destruction into the San Francisquito Canyon and the Santa Clara River Valley of southern California will eventually be revealed. The appalling fact is all that is certain at this writing, and its contemplation is far from gratifying to the engineering profession. Covering the blot for the present, however, with a mantle of charity, let us look with eyes undimmed by passion on the triumphs of engineering and of human relationships brought into action by the catastrophe.

Two generating stations of the city of Los Angeles, with an aggregate rating of 93,100 kw., are temporarily paralyzed because of the disaster. The Southern California Edison Company—thanks to its now adequate steam reserve—quickly took over the load of the municipal system and enabled the citizens of Los Angeles, so far as electricity supply was concerned, to go about their business as though nothing had happened. Magnanimous, one might say, considering the rivalry existing between the Power Bureau of the city of Los Angeles and the Southern California Edison Company; but nothing less could be expected of the Edison company. Engineering is no respecter of persons and calamity wipes out all rivalry. Besides, Chairman Miller, President Ballard and the entire Edison organization are so rooted and grounded in traditions of service that if human impulses and the needs of California did not stir them, their natural instinct for service would. The industry sympathizes with the Power Bureau in its affliction and rejoices in the fact that the Edison company so amply justified the confidence in it that every one familiar with its history and its spirit entertained.

## *New York Legislature Passes Savings Bank Investment Bill*

PASSAGE without debate and without opposition by the New York Assembly of the bill authorizing savings banks to invest in the bonds of public utility companies doubtless presages its approval by Governor Smith, although Democratic senators from New York City opposed it. For more than five years the savings banks of New York have tried to get the state to permit them to invest in gilt-edge utility securities and now it appears that success will at last crown their efforts. This means that the utilities of the country will find the market for their bonds considerably widened and their credit position thereby strengthened.

Savings bank deposits in New York amount to $4,000,000,000, but, of course, all of this is not available for utility investment. Under the terms of the bill, however, at least $500,000,000 could be thus employed, enough to absorb many years' offerings of bonds measuring up to the standards set. This illustrates the size of the market with relation to the volume of offerings, and it is encouraging to feel that as other states liberalize their requirements the savings banks will absorb more and more of amply protected public utility securities.

## *Mass Production in Steam Generation*

ON THE frontier of steam-generation developments the high-powered boiler unit is the heavy artillery of the advance. Recent improvements in furnace design centering upon the use of water-cooled walls and greatly increased volumes of combustion space point the way toward the building of boilers of colossal ratings compared with former units. Thomas E. Murray recently told the Midwest Power Conference that plans are now being made for boilers each having a capacity of 800,000 pounds of steam per hour; that the next installations will go to one million pounds per boiler, and that we may expect soon to have units large enough to supply individually all the steam required by turbines of 300,000 kw. or even greater rating. This development will not be a mere evolution of sizes, but will be accompanied by many radical changes. Mass production of steam will be the keynote of progress, however the line of development may swing toward or away from particular generating processes. Only by this means can the over-all efficiency and reliability of service now demanded by users of electricity produced from fuel be assured.

The art of steam generation bristles with interrogations. The economic values of the water-cooled furnace need to be brought out more widely from experience. The last word has not been heard from the manufacturers of refractories, if engineering history is instructive. The extent to which decentralization is desirable in pulverization systems, the place of unit dryers, use or non-use of air-heater and economizer combinations, simplification of boiler-control systems, betterment of practice in scale prevention and the choice of steam pressures and temperatures from the standpoint of dollar efficiency are all pressing problems. The performance of a commercial installation of the mercury vapor-steam process of power generation on the substantial scale embodied in the new South Meadow application at Hartford is awaited with intense interest. Other designs of steam generating apparatus are pressing for consideration here and abroad. Truly remarkable strides are being made, and while it is somewhat disappointing for the builder of a new station to be obliged to modify his plans for its enlargement almost from the day when its B.t.u.'s begin to return money on the investment, the keen struggle for over-all economic efficiency in the modern mass production of power presses irresistibly upon designer, operator and equipment manufacturer. Growing pains are not less healthful because of their acuteness.

* * * *

## *Senate Favors Government Operation of Muscle Shoals*

AFTER nearly three weeks of discussion, the Senate on March 13 passed the Norris bill dealing with Muscle Shoals. Senator Norris in his original measure sought to employ the proceeds obtained from government operation for experimentation with synthetic fertilizers requiring very little electricity. As the debate developed, however, Southern senators refused to abandon Nitrate Plant No. 2, which Senator Norris insisted was obsolete, and an agreement was reached whereby Plant No. 2 will be utilized to produce cyanamid, to determine whether it can compete commercially with the synthetic product. In order to secure Norris' support, however, the Southern senators had to agree to governmental distribution of power. Thus they defeated the amendment of Senator Harrison of Mississippi which would have eliminated the purely government operation feature of the Norris bill.

Under the measure as passed by the Senate, it is doubtful whether the Secretary of War will have much power to sell to the Southeastern power companies, because Plant No. 2 will require about 100,000 horsepower and states, counties and municipalities have a prior claim over private companies. Under the circumstances, therefore, and because of the fact that the power is subject to withdrawal for war purposes, the outlook for the power companies is not inviting. While no doubt an important factor influencing the vote of many senators was the "backwash" from discussions and action on the Walsh resolution to investigate the electric light and power industry, the result does not, as one senator insisted, "blaze the trail across the map of the United States for nationalizing the power industry."

The measure is now in the hands of the military committee of the House of Representatives, where other Muscle Shoals bills are under scrutiny. Whether there will be final legislation on Muscle Shoals at this session is problematical, although if the military committee reports the Norris bill favorably, the House, in its desire to rid itself of the Muscle Shoals white elephant, may approve it. The best interests of the South would decree otherwise, but politics is politics.

## *Counsel Needed on What Housewives Think*

MORE than any other industry in the world, the electric light and power industry touches the people. It is not like the steel industry, which sells to railroads, to building erectors, to great manufacturers, and only through remote channels affects the individual. It is not like agriculture, which reaches its objective through the miller, the baker, the canner and the grocer. It is not like any industry in the world, because it touches at first hand every class and almost every individual, and it touches them almost every day. When the smallest customer snaps a switch he is in direct and instant physical contact with the company which supplies the energy he seeks. This truth places a heavy and unusual obligation upon the electrical industry's leaders. It requires that they shall know, appreciate, sympathize with and directly serve society down to its very dregs.

There is evidence that the central-station industry has been partial to "high hats," speaking in the vernacular, and to professional dignity. But this policy is bad for business, because the business deals with the humanities. Public servants must be "folks." If they cannot themselves be "folks," they must be guided by men who are. "I know of nothing more ridiculous than a gray-haired board of directors deciding on what housewives want," says a successful advertising man. Here in a sentence is a bookful. The men who decide "on what housewives want" should be men who know housewives—men who sell to housewives—men who understand how, why and when housewives think, and about what. These men are the salesmen. The salesmen should be invited into the industry's higher councils. They are needed.

* * * *

## *Record of the Electrical Manufacturers' Association*

THE progress which is being shown in the growth and development of the National Electrical Manufacturers' Association is an excellent example of the benefits that so often result from the patient process of making haste slowly. Last summer there were 285 electrical manufacturing companies listed in the membership and today there are 310. This in itself is significant. For manufacturers have always been by nature individualists. Industrial competition was originally just commercial warfare in which each man kept his own counsel and endeavored to outwit and to outsell his rivals. Then came the idea of co-operation. It was good and it took root. The trouble was that, as is so apt to happen, men in their enthusiasm went too far and their sound principle of co-operation for economic efficiency began to be distorted into selfish conspiracies among manufacturers against the public. Congress rallied to the defense of the people with the repressive and restrictive Sherman act and Clayton law. And manufacturers of all industries who had just begun to learn to work together were driven apart again. It has taken a long while for industry to discover what are really sound and safe purposes for organized co-operation, to regain confidence in the practical possibilities of association work and to restore a fair measure of enthusiasm.

It was natural, therefore, that when the electrical manufacturers year before last combined their apparatus and supply groups in one organization they should go forward cautiously. This spirit has been apparent in their meetings. Vigilant counsel has been a conspicuous brake on action, that the slightest appearance even of evil thought might be avoided. And this, of course, was right. Many have been impatient at times, however, that more constructive activities have not been undertaken more quickly. This is unavoidable until a revision of these laws some day shall give to industry the right to plan and build more freely in the public interest, in tune with the advancing thought of our increasingly industrial America.

The important point is this, that the N.E.M.A. is growing. It has more members, and these companies are gradually discovering and developing the elements of common interest and common purpose on which they may profitably work. Such groups must learn to discuss their problems freely together before they can expect to help one another solve them. The great need is always for facts, for the light of economic truth on which to base discussion. So they have been evolving a code of ethics and merchandising principles, and already eighteen sections of the association are compiling industry statistics on classes of products. These figures are incomplete and inadequate, but here is a start, of vital value to all branches of the electrical industry. And "Nema" should have the sympathy and support not only of all electrical manufacturers but of all electrical men.

* * * *

## *Mechanization and Unemployment*

IT IS alleged that mechanization of industry and the use of power produce unemployment and that existing conditions reflect this development in American industry. Some so-called cultural writers and some labor agitators seize this statement and use it with much apparent satisfaction. From census statistics it can be shown that present production methods can accomplish the 1914 volume in manufacture with about 30 per cent decrease in the number of workers and that this trend continues. Other data show that while the productive output per worker increased 40 per cent between 1914 and 1925, in the same period the total manufacturing production increased 65 per cent. Expanded markets because of lower costs of goods not only absorbed the 30 per cent of workers but called for 1,500,000 more workers in manufacturing plants. An increase of 1,500,000 workers and the use of 13,750,000 hp. additional power resulted in an increase in production of $39,000,000,000 in the twelve-year period.

The process of mechanization is a gradual one in all branches of industry, and in each branch it makes for employment instead of unemployment. It has made an increase of 40 per cent in national wealth and in national income since 1914. It has made possible new industries and the relocation of workers in a manner enabling them to secure continuous employment despite fluctuating business conditions in any single industry. It has reduced the cost of management 10 per cent and doubled the wages of workers since 1914. There is no basis for dire forebodings as to unemployment because of the mechanization of industry. This trend in the past as in the future offers the greatest available tool to improve the status of workers and lift them out of the "coolie" standards of living, if such standards still prevail in any occupation.

* * * *

## *Interchange Energy Introduces Metering Problems*

ON TRANSMISSION systems with extensive interconnections across state lines a difficult metering problem is encountered. For many reasons it is desirable to know the exact electrical quantities at each state-line crossing, but it is questionable whether the cost of metering equipment can be justified. At present very little energy crossing state lines is metered accurately, because values are based on generating-station energy measurements, energy sold to customers and estimated line loading and losses.

Generating-station metering is accurate and detailed for each hour of the day, but customer meter readings are monthly summations. As a consequence it is difficult to fix exact values for hour-by-hour or day-to-day kilowatt-hours and kilovolt-ampere-hours which cross state lines. Line loading changes rapidly, and electricity may flow in either direction during each day. With complex transmission systems it is difficult to draw an exact system load map for each day, and estimates are far from accurate.

Data on state line interchanges or at connecting points between utility systems have value largely as statistics and mean little to economic operation. Such data would help in allocating loadings for lines and stations more accurately, but it is questionable whether this would warrant a large investment in metering equipments. If a recording metering equipment for these applications can be developed at a low cost, there is little doubt that it would be used very extensively. The precision required is less than that for meters used in billing customers, and it would seem possible to develop high-tension metering equipment for this special application at a reasonable cost and in such a way as to decrease the service hazard introduced by current methods of metering.

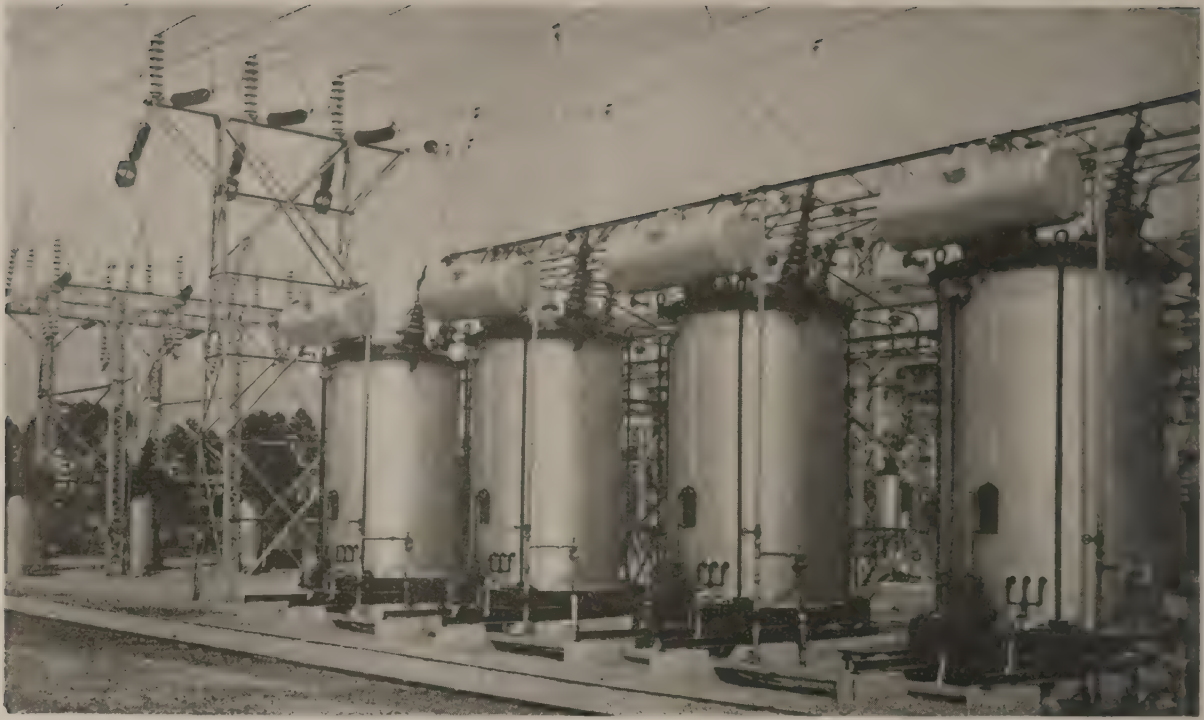
* * * *

## *Prime Movers and Interconnection Stability*

WITH some reservations, the stability of interconnections between electrical systems is a measure of their value. It is not suggested that interconnections shall be so solid that in case of major trouble all of the systems shall stand together and valiantly and uselessly go down together. Neither is it intended that when a relatively small disturbance occurs they shall immediately separate like the sections of a glass snake and leave the afflicted part to suffer alone. But often enough to be embarrassing the systems in some interconnected groups, particularly those covering large areas of low-load density and linking together comparatively small and comparatively old generating plants, will perform in exactly the second way. They drop apart in spite of the very best intentions of their operators to keep them together.

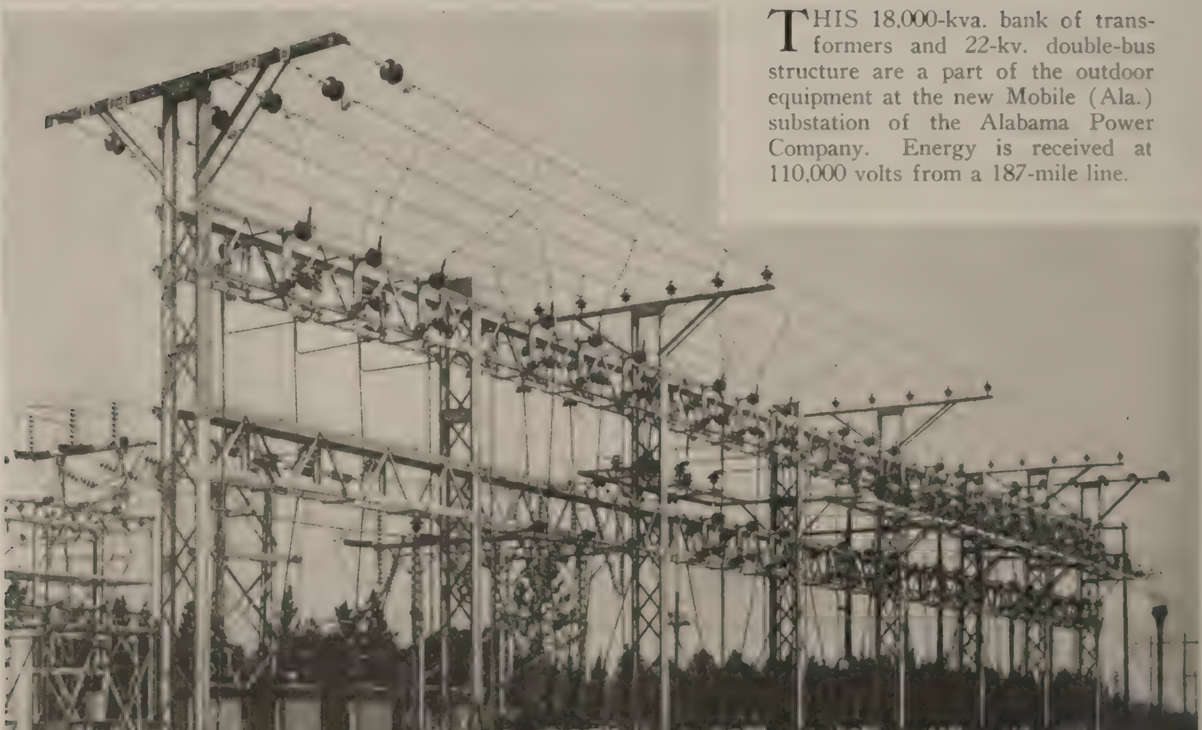
Possibly the trouble is due to lack of synchronizing capacity in the connecting lines. Or it may be due to hunting tendencies or the excitation responsiveness of the generators. In avoiding such weaknesses, however, the overload capacity of the prime movers should not be overlooked.

Sometimes the interconnected plants contain machines which supinely drop out of step whenever they receive a momentary heavy overload or secede from the union on equally trivial provocation. One holding company that controls a series of interconnected properties has laid down a policy in prime-mover purchases that is designed eventually to overcome this difficulty. All turbine units are specified to be able to carry a 50 per cent overload without reduction in speed for a period expressed in minutes. This specification does not affect the generator design, because the overload period is not long enough to produce an appreciable temperature rise. It affects only the steam end of the unit and in such a way as not to increase the cost or to decrease the normal operating efficiency. A unit of this kind will, of course, require that the boilers and auxiliaries be competent to carry their share of the overload. This requirement, however, merely makes it necessary that the overload performance be kept in mind during the course of plant design and shall not add greatly, if at all, to the cost.



# *New Automatic Substation in the South*

THIS 18,000-kva. bank of transformers and 22-kv. double-bus structure are a part of the outdoor equipment at the new Mobile (Ala.) substation of the Alabama Power Company. Energy is received at 110,000 volts from a 187-mile line.



# Single-Phase Condenser Motor

### Fractional horsepower motor characteristics, effect on economy of operation, application requirements, condenser motor theory and operation discussed

By Prof. BENJ. F. BAILEY
*University of Michigan*

UNTIL recently the users of small motors were interested only in price and reliability. Motors used for such purposes as operating vacuum cleaners, sewing machines or fans run only a small portion of the time and the cost of the energy consumed is negligible. The user is therefore not interested in efficiency, and as a rule knows nothing about the power factor or other characteristics of the motor. The central stations were not particularly interested since the connected load was small and was on the line only a small part of the time.

With the common use of electric refrigerators and oil burners requiring an electric motor the situation has radically changed. Such motors are used in enormous numbers and they are in operation a large percentage of the time. The user therefore should be interested in efficiency, since his monthly bill is considerable.

The average domestic refrigerator if equipped with some of the low efficiency motors now on the market will consume 750 kw.-hr. per year. By using the most efficient type of motor this may be cut to 500 kw.-hr. If energy costs 5 cents per kilowatt-hour the better motor will effect a yearly saving of $12.50. The saving in one year will easily pay the difference in cost between the two motors. In addition, the type of motor herein described is notably quieter than the usual single-phase motor and causes less interference with radio reception.

The progressive central station is interested in seeing that the motors on its lines are high in efficiency and power factor and require a low starting current. A low efficiency motor of course consumes more energy and therefore increases the central station revenue. On the other hand, small bills encourage the use of electrical appliances. When high-efficiency electric lamps replaced the old carbon-filament lamps the consumption of energy by no means decreased, but, on the other hand, showed a marked increase. Doubtless an improvement in motor efficiency would have a like effect in increasing consumption.

The central station is paid only for the energy consumed, since it is impracticable to meter power factor in domestic installations. The refrigerator and oil burner motors both operate on the peak of the load. A motor of low power factor is bad from the standpoint of the central station, since it requires a large current and consequently larger generators, feeders, transformers and switches. The best available ¼-hp., 110-volt, alternating-current motors require a current of only 2.5 amp. at full load, while the worst require 6.5 amp. It is rather surprising to find that to supply the better motor a metropolitan central station must make an investment of approximately $55 and for the poorer one $78, a difference of $23. The difference in cost between the two motors is far less than this. When a better motor is used the central station also gains by reason of better voltage regulation and lower losses in its feeders, generators and transformers.

Realizing the importance of the growing small motor load the Detroit Edison Company some three years ago financed an investigation of the characteristics of the fractional horsepower motors actually on the market, and about 25 small single-phase motors were carefully tested by the writer and his assistants. Some of the results obtained are shown in Figs. 1, 2 and 3. These motors are of the repulsion-induction and split-phase types. No condenser motors are included.

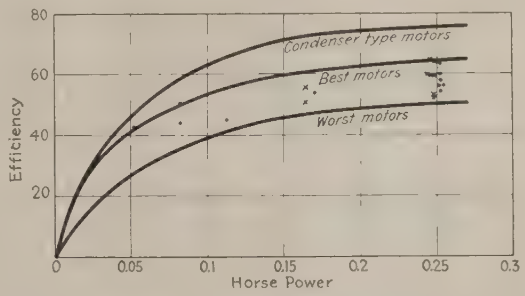


*Fig. 1—Efficiencies of small motors, 110-volt, 60-cycle, 1,800-r.p.m. Split-phase motors indicated by dots and repulsion-induction motors by crosses*

In Fig. 1 the full-load efficiencies of the motors tested have been plotted and two curves drawn showing approximately the best and the worst efficiencies of the present day commercial motors.

Considering, for example, the ¼-hp. motors, a simple calculation shows that the worst motors on the market, with efficiencies of about 50 per cent, consume about 373 watts at full load. The best commercial motors, with 64 per cent efficiency, require only 292 watts. If we compare the monthly bills of consumers using the poorest motors with those using the best motors it can be seen that there is a difference of 28 per cent.

On the same curve sheet I have also plotted full-load efficiencies which have actually been obtained with the condenser motors to be described later. It is entirely possible to obtain an efficiency of 75 per cent with a ¼-hp. condenser type motor. Such a motor would require only 250 watts for full-load operation and the monthly bill would be approximately two-thirds as great as with the poorest of the present-day motors, or approximately 85 per cent as great as with the best of the present-day motors.

In Fig. 2 I have plotted corresponding curves showing the power factor of small motors. The difference between the poorest and best motors is approximately the same as before. The upper curve shows power factors which can readily be obtained with condenser type motors. By using somewhat larger condensers it is perfectly possible to raise the power factor to 100 per cent, or even to cause the motor to take a leading current. In fact, condenser type motors are now on the market having power factors of more than 95 per cent. How high we should go is merely a question of how much it is worthwhile to invest to secure a high power factor.

In Fig. 3 I have shown the apparent efficiencies of small motors. The apparent efficiency is obtained by multiplying together the efficiency and power factor. Since the motors which have the lowest efficiencies usually have the lowest power factors as well, the divergence between the curves of best and poorest motors is even greater than before. It will be noted that some ¼-hp. motors have an apparent efficiency as low as 25 per cent, while the best run as high as 43 per cent. The condenser motor can easily be built to have an apparent efficiency of 65 to 70 per cent. The current required by such a motor is not much more than one-third of that of the poorest present-day motors and about two-thirds of that required by the best motors of other types. It is obvious from the standpoint of the central station that it is much cheaper to provide facilities to supply a motor requiring less than 2.5 amp. at full load than to supply one requiring 6.5 amp., and it is equally obvious that it is to the advantage of the customer to receive a monthly bill of $2 rather than one of $3.

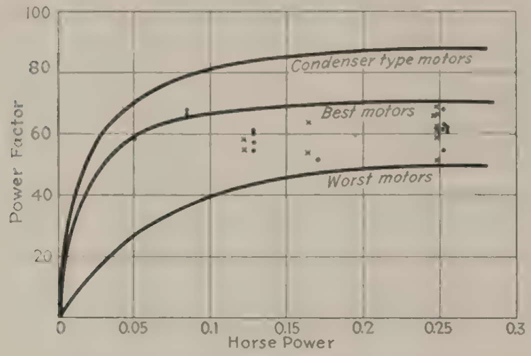

*Fig. 2—Power factors of small motors, 110-volt, 60-cycle, 1,800-r.p.m. Split-phase, dots; repulsion-induction, crosses*

### SPLIT-PHASE AND REPULSION-INDUCTION MOTORS

The circuits of a split-phase motor are shown in Fig. 4. The primary winding is usually on the stator, although it is sometimes placed on the rotor, and consists of a two-phase winding wound in slots. The winding marked 1 is the main or running winding. Winding 2 usually has fewer turns than winding 1 and is wound with finer wire. The switch $S$ is ordinarily automatically operated by centrifugal force, so that it opens when the motor attains its running speed. The non-inductive resistance marked $R$ is rarely present as a separate element, but the necessary resistance is secured by using finer wire in winding 2. This has the obvious advantage of cheapness. The rotor is usually of the squirrel-cage type.

When a motor must exert considerable starting torque with a low starting current the repulsion-induction type of single-phase motor is preferred. The stator is similar to that of a split-phase motor except that only a single winding is used. The rotor is like that of a direct-current motor having a commutator and brushes. These brushes are short circuited to one another and are not connected to the supply circuit. When the motor reaches nearly full speed a centrifugal device operates and short circuits the bars of the commutator to one another. The motor then operates as though it had a squirrel-cage armature. Its characteristics during normal running do not differ materially from those of the split-phase motor.

### SPLIT-PHASE MOTOR STARTING

The vector diagram of a split-phase motor when starting is shown in Fig. 5. $I_1$ represents the current in the winding 1 and it lags by a large angle behind the voltage $E$. The current $I_2$ in the winding 2 lags by a much smaller angle due to the fact that this winding has a relatively high resistance compared with its reactance. The two currents are therefore at an angle $\alpha$.

For the best results this angle $\alpha$ should be 90 deg., but it is obviously impossible to secure such an angle with this construction. The starting torque developed is proportional to the ampere turns in each of the windings, namely $N_1I_1$ and $N_2I_2$, to some constant which we will call $Q$ and to the component of $I_2$, which is perpendicular to $I_1$. It is then given by the formula

$$\text{Starting torque} = QN_1N_2I_1I_2 \sin \alpha.$$

In order to get sufficient starting torque in motors of this type it is necessary to make $N_2$ small. For a given size and weight of wire the impedance of the winding 2 is proportional to the square of $N_2$ and the current of $I_2$ is therefore inversely proportional to the square of $N_2$. The product $N_2I_2$ will therefore become greater as $N_2$ becomes smaller and the starting torque will be correspondingly increased. The number of turns $N_1$ in the main winding is of course fixed by the design of the motor and cannot be made unduly small without impairing the characteristics of the motor. Such a motor will quite obviously take a large starting current and develop only a comparatively small starting torque. The starting torque can, however, be made from 150 to 200 per cent of the full load running torque, but only at the expense of a large starting current.

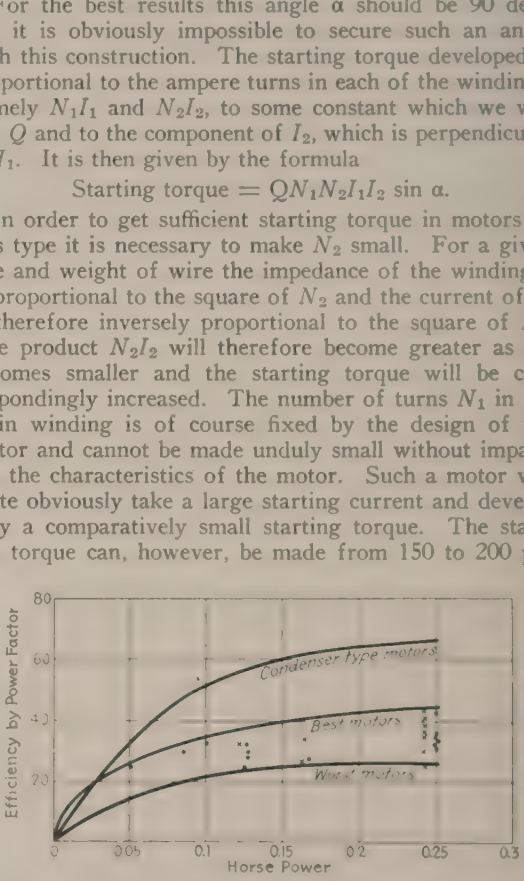

*Fig. 3—Apparent efficiencies of small motors, 110-volt, 60-cycle, 1,800-r.p.m. Split-phase, dots; repulsion-induction, crosses*

The starting efficiency of any motor can be determined by the following formula:

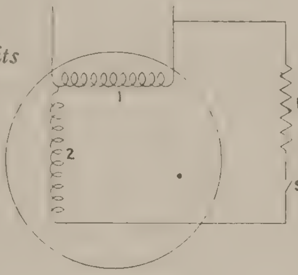
$$\text{Starting efficiency} = \eta = \frac{0.142\ TS}{\text{Volt-amperes}}$$

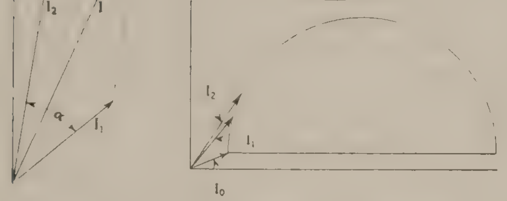
in which $T$ is expressed in pounds feet and $S$ is the synchronous speed in revolutions per minute. In the case of a polyphase motor proper allowance for the number of phases must of course be made in computing the volt-amperes.

The starting efficiency of a shunt-wound direct-current motor as determined by this formula is nearly 100 per cent, $S$ in this case being the free running speed of the motor. In the case of an alternating-current motor, $S$ is the synchronous speed and the starting efficiency is lower. For a squirrel-cage polyphase motor it is in the neighborhood of 20 per cent and for a wound-rotor polyphase motor about 50 to 60 per cent. In the case of the split-phase motor it is very low, being about 8 to 10 per cent. In other words, such a motor takes about ten times as much current for the same starting torque as a shunt-wound direct-current motor.

Under normal running conditions the switch $S$ is open and the winding 1 is alone active. The vector diagram of such a motor at full load is shown in Fig. 6. The current is shown lagging behind the voltage by a considerable angle. As is well known the locus of the end of the current vector for varying loads is approximately a circle. The current at very light loads is represented by such a vector as $I_0$, at full load by such a vector as $I_1$ and for overloads by such a vector as $I_2$. The power factor can never be 100 per cent. In general, it increases with the load up to about 50 per cent overload; beyond that it decreases.

*Fig. 4 (right)—Circuits of split-phase motor*





*Figs. 5 and 6—Vector diagrams for split-phase motor, starting and running, respectively*

Compared with a polyphase motor, such a motor has the disadvantage that it requires a very large starting current. Its output is small since the running winding occupies only a portion of the available winding space and its power factor is lower than that of a polyphase motor.

[The second part of Professor Bailey's discussion of the single-phase condenser motor will appear in an early issue.—Editor.]

## Hydro Plant Taps Two Watersheds

THE Great Falls hydro plant of the Tennessee Electric Power Company utilizes the waters of the Caney Fork River and also draws a supply through another penstock from the Collins River, which flows on the far side of a mountain ridge behind the plant. These two streams afford a reservoir equivalent of 6,000,000 kw.-hr. for the station, whose capacity is 35,510 hp.

# Long Cable Sections Reduce Expense

### Decrease number of manholes, splices, bonds, fireproof coverings, operating hazard, cost of cable, handling and installation

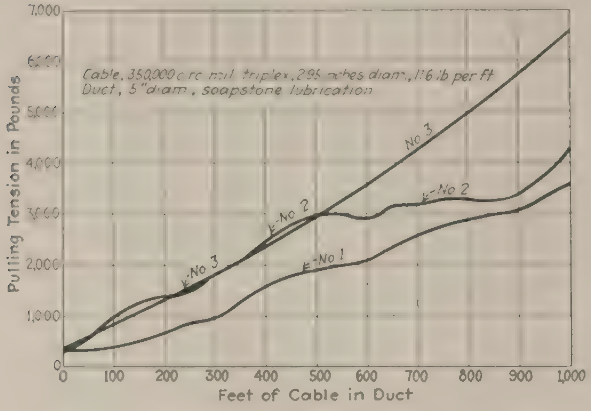
By C. H. Shaw
*Engineer Distribution and Installation Department, New York Edison Company*

MANHOLES and conduit structures are far more permanent than any cables that may be installed in them, so that in every important installation the design and arrangement of these facilities are usually based as much upon the expected requirements of the future as upon the immediate needs. The cost of the conduits and manholes is always very much greater than the cost of the cables installed in them, and when a large allowance is made for later growth the investment may be ten to twenty times the immediate cable cost. But since the increment cost of building one, two, four, or eight additional conduits, after the excavation, backfilling and repaving have once been undertaken, is only a fraction of the cost of the complete project, extra facilities are usually included with the original construction to secure the ultimate minimum cost per duct-foot of conduit.

Several new conditions have caused very rapid advancement in the design of underground conduit systems during the past two or three years. First, the unprecedented increase in the operating voltages for which cables have been designed has made it imperative that the detail arrangement of the cables in the ducts and the training, method of support and splicing of the cables in the manholes shall have expert engineering supervision; second, the introduction of large single-conductor cables, installed either singly or in multiple in the ducts, has made it advisable to increase the diameter of the ducts for many important feeder lines from the old standard of 3 in. to 5 in.; third, with the continuing advance in the operating voltages of underground transmission cables and the steadily increasing size of the generating units that are installed in the power stations it is important that the relatively permanent conduit structures be built of such sizes as will not in the future restrict the use of larger and higher voltage cables.

When the monolithic concrete conduit system that was later to house the highly successful 132,000-volt feeder cable in New York was under construction there were no data available upon which to base a decision as to the maximum length for which the conduit sections should be designed. But with the later adaptation of a continuous reading dynamometer, from which the pulling stresses required to draw cable into ducts could be secured readily, it became possible at once to develop new and more efficient methods for lubricating the cable during the pulling-in process and to discover the most advantageous lubricant for each type of conduit. These tests showed that the friction between the cable and the concrete walls of Murray monolithic conduits was almost entirely dependent upon the unit weight of the cable itself, as long as the cable was not too large for the duct.

Long sections of cable have several advantages. They reduce the number of manholes that are required in a given line and, as manholes are expensive, effect an important saving in the initial cost of construction. With a reduction in the number of manholes there is a corresponding saving in splicing, bonding and fireproofing of cables. The manholes are unquestionably more hazardous for the cables installed in them than are the individual ducts entirely surrounded by concrete. The cost of manufacturing long sections of cables is less per foot than for short sections, since all of the fixed processes, such as reeling up, impregnating, testing and crating, are almost independent of the length of cable section. With double the length of cable the unit cost of these processes is halved. The cost of installing one section of cable 1,000 ft. long is much less than the cost of pulling in two sections of 500 ft. each, and the investment in reels, cost of carting the cable to the job and of handling the empty reels is almost half as much per cable-foot for the long section as for two short ones.



*Tensions required to pull three* 1,000-*ft. cables into Murray monolithic duct*

After the completion of the tests that revealed the low coefficient of friction that exists in properly lubricated Murray monolithic conduit structures, it was decided to build the maximum-length sections for which cable could be manufactured on an important underground transmission system from Dunwoodie substation in Yonkers to the Elmsford substation in Westchester, a distance of 11 miles. As the highway has a great many curves, only a few 1,000-foot straight sections could be fitted in. And as three single-conductor, 45,000-volt cables are to be placed in each duct the total weight of cable per duct-foot probably will be greater than ever before installed in so large an undertaking. In the first 7,000-ft. portion of the line to be finished there are three 1,000-ft. sections. With the completion of a series of trial tests it has been found that it will be practical to place the three 45,000-volt cables in one duct. All of these will not go in at one time, but will be installed in two operations, which will call for one cable first and for two cables to be drawn in over the first one in the second pull. The maximum pulling stress will not exceed 5,000 lb. per cable.

Over a portion of this line provision was made for the additional installation of two 13,200-volt feeders, and because of some unexpected developments it happens that one of these lower voltage feeders was the first to be installed for permanent operation. The installation of the three-conductor, 350,000-circ-mil triplex cable introduced an interesting problem, as the cable for this job was used cable, on hand in relatively short sections. These sections were duct-spliced in the salvage plant of the New York Edison Company to lengths of not more than 500 ft., this being the maximum length of this size cable that can be placed on a large standard reel. In order to install the 1,000-ft. sections a 500-ft. piece was first pulled in, with the end left above ground so that the duct-splicing crew could bring its equipment into the field and make a duct splice between the two 500-ft. sections, after which the cable was pulled in the remaining distance. This procedure was followed in several other sections of less than 1,000 ft. where the cable could not be placed on a single reel. The pulling tension of each of the three 1,000-ft. sections is shown in the accompanying diagram. The duct curve No. 3 had a slight bend in it, which accounts for the greater stress required than in the two other cases. This feeder, upon completion, was tested at 67,000 volts direct current for five minutes with a portable kenotron set and was found free from fault. If new 13,200-volt cable had been used it would have been made up as three single-conductor sections, each 1,000 ft. long and each on a separate reel. All three sections would have been pulled in together.

Unless manholes and duct entrances can be designed for expansion and contraction long cable sections cannot be used as the lead sheaths would crack. Experience shows that devoting careful study to the details of conduit and manhole design and construction not only reduces unit costs but produces much more acceptable cable operating conditions. The day of building important conduit lines without accurately prescribed grades and curves is over, and to consider that conduit construction is a mere pick-and-shovel job, as has been done all too frequently in the past, is much like leaving the design of the façade of an expensive building to the master bricklayer. While the developments that have been mentioned have been largely in connection with monolithic conduit construction, the tests that have been reported by the more important utility companies throughout the United States show an increasing appreciation of the importance of adequate engineering supervision.

# Capital Investment Rate Base*

### Economic defects of proposed Massachusetts plan of regulation. Inflation likely to follow application of price fixing to maintain stocks at par. Public welfare faces risks if bill passes

By PHILIP CABOT
*Head of Public Utility Courses*
*Harvard Graduate School of Business Administration*

A BILL before the Massachusetts Legislature (House 170) embodying the recommendations of the Governor and indorsed by the Department of Public Utilities proposes to create a new relation between the companies and the state by means of a contract fixing the amount paid in by the stockholders for stock and premiums as a permanent rate base on which the stockholders are entitled to receive a fair return, and rates are to be regulated in such a way that the profits of the companies shall be sufficient, but not more than sufficient, to keep the market price of the stocks at or above par. The object of this legislation is to obtain a necessary service for the consumers at the lowest possible price. This object is sound and wise, but I do not think that it can be reached by this method, because it violates certain fundamental economic principles. I shall confine myself strictly to these principles.

## RATE BASE MEASURED BY 65-CENT DOLLARS

The reason that this problem has arisen at this time is because of the wide divergence between the original cost of these utility properties and the present cost of reproducing them. This is an economic phenomenon observable in all business. There has been a general rise of prices since 1914 and the wholesale price index figure now stands at about 147, as compared with 100 in 1914. Now all economists agree that a general rise in prices is merely another way of saying that the value of the dollar has fallen. What has happened in this case is not that the prices of goods measured in other goods have risen, but that the yardstick with which we measure the goods is shorter. Values in most cases are not really higher than in 1914, but the dollars in which we measure them have shrunk to 65 cents.

What is proposed is that the property of these public utility companies shall be measured in these 65-cent dollars and that the value thus found shall be adopted as a permanent rate base and used to fix just and reasonable rates. Disregarding the possible injustice to investors of such a course, it would seem to be advantageous to the consumer because the purpose is to fix values at a low figure so that prices may be low and the consumer may benefit. If the value of these properties were measured by comparison with the prices of other goods and services; that is, on the basis of cost of reproduction new, the values and therefore the prices would be much higher.

Such consideration for the welfare of the consumer is commendable, but the question arises whether in the long run it will really benefit the consumer. I hold that it will not.

When prices rise, as they have in the last twenty years, it indicates primarily an increase in the demand for goods. For example, when the cost of building material rises it shows that more people are building houses, thus creating a demand for such material. Under normal conditions such a rise of prices works in two ways: (1) It tends to control the increase in demand, and (2) it tends to stimulate production of these materials and increase the supply. Prices will continue to rise until the demand is checked and the supply has increased, so that equilibrium has been re-established.

Now in the public utility business, production is increased by law; the companies are required to supply all the service that is demanded,† and under the method of regulation proposed by this bill prices, instead of rising to check the demand, are to be reduced. Thus the demand will be stimulated instead of being checked and the business will be expanded more rapidly than it would have been if the check of rising prices had been applied. Lowering prices always have the effect of increasing demand when the market is what economists call an elastic market. Most markets are more or less elastic—that is common knowledge—and the market for gas and electricity is very elastic, as the experience of the last twenty years has proved. It is, therefore, as certain as any economic result can be that if prices are reduced at the present time, when the demand for these services is excellent, the business will expand at a rapid and an abnormal rate.

## PRICE FIXING BEGETS INFLATION

This increased demand will require the expansion of the producing and distributing plants of the companies, and the expansion of them at a time when prices are high. The stimulation of demand by a lowering of price will force an abnormal expansion of plants and is likely to result in an overdevelopment of these industries. We have an ugly name for this sort of thing; we call it inflation, and it is a thing which we have learned to fear. It has often resulted from the efforts of governments to fix prices; in fact, it is the usual result, and we know that the ultimate effect on the consumer is bad.

The danger of inflation which I apprehend as a result of the method of price regulation proposed by this bill is the same as the dangers of currency inflation, with which you are all familiar, except that currency inflation affects all lines of business and this inflation will affect the public utilities alone. But the investment in them is

---

**From an address to the legislative committee on power and light at Boston.*

†*Except in case of unprofitable extensions.*—[EDITOR.]

already very large, and if inflation of this industry is forced upon us by the action of the state the damage will be serious.

The matter is so important and the danger of it so great as to warrant a more detailed explanation. This is the way in which I think the thing will work. The demand for gas and electricity will be stimulated by low prices fixed by a rate base which will be about 50 per cent below the present cost of reproducing the properties. This increased demand will require the rapid expansion of the properties in the immediate future when prices of labor and material are high. As long as the prices are held artificially low, demand will continue to expand until a condition of inflation results. Under this bill the new plants will be paid for by new security issues, on which the state must practically guarantee a fair return because the stocks are to be maintained at or above par.

As long as the business continues to expand no difficulty will be encountered, but ultimately the end must come. A turn in the business cycle will come, demand will begin to fall and depression will set in. Then we shall be in trouble. The industry will be overexpanded; as demand falls off a large part of the plant will be idle, and revenues at current rates will be insufficient to pay fixed charges. An increase in rates will be necessary in order to maintain the prices of the stocks and this increase will come just at the time when there should be a decrease. Other prices will be going down, other business will be depressed, and in order to lift industry out of its depression lower prices for gas and electricity for industrial uses ought to be made. But that will be impossible. Regulating commissions will never stand the odium of raising prices for domestic service in order to help business. The rates for domestic service will stay down and rates for industrial service will have to bear the whole increase. The resulting burden on the community is difficult to gage, but it may be staggering.

### Bad Effect on Business Cycle

There is another economic angle from which this can be seen. The best brains in the country are being applied to finding some way to do away with the evils of the business cycle, or at least to mitigate the severity of it, but if this method of public utility rate regulation should be generally adopted the severity of the cycle would be very greatly increased. Artificially low prices in times of prosperity will force the utility companies into the market for labor and materials at the very worst time; that is, when prices are highest because business is good. When the depression comes the utility companies will be out of the market because their plants will be overbuilt and, to make matters worse, they will have to exact an increased price from industry when it can least afford to pay it.

By agreeing to fix rates which shall enable the companies to keep the prices of their stocks above par the commonwealth is repeating the blunder made in the public control act for the Boston Elevated Railway. Dividends in the stocks of the gas and electric companies will not be guaranteed, but when depression comes prices will have to be raised so that dividends can be earned, while the stockholders, who ought to take the risks of the business, sit back and let the commission do the worrying.

I am led to believe that this is a sound forecast of what may happen in the gas and electric industries by the example of what has actually happened to the electric street railway companies. These companies did, without intending it, just what I have described above. In fixing the 5-cent fare they set the price too low; the result was a rapid expansion of the business, ending in overexpansion, and when they tried to retrace their steps by raising their fares they found that the amount of business which they could get at the higher prices was too small to pay a fair return upon the plant. In most cases the stockholders stood the loss, but if the state had agreed to fix fares at a point which would keep their stocks above par the dilemma would have been serious, because we know by experience that there are many cases where no rate of fare which the public will pay is high enough to earn a return on the capitalization of the street railways. Just such a condition may arise in the gas and electric industry if the provisions of this bill are carried out. The plants of the companies may be expanded beyond the point where any rates that can be collected in times of depression will keep the stocks of the companies at par. In such a condition the state would be helpless. It would have agreed to fix prices which would accomplish this result, but it would be beyond its power to do so. Even the Commonwealth of Massachusetts must bow before the economic law. But the situation would be most humiliating and it is unnecessary.

There are already visible upon the horizon clouds which indicate that inflation is at hand in certain places in the electric power industry. This may perhaps be due to public regulation as now generally practiced, but the point is not clear. A certain rigidity in price regulation is unavoidable under any method of government control. There is bound to be delay in adjusting prices to changing market conditions, and the atmosphere of controversy and the spirit of litigation which hang like a cloud over all rate inquiries before the regulating commissions tend, so to speak, to make the visibility low. But the present methods have this great advantage over the method proposed by this bill. If inflation comes, and is followed by collapse in some cases, the state is not responsible for the losses which may ensue. These will fall where they belong, upon the stockholders.

I conclude, therefore, that the method of regulation proposed by this bill is not in the interest of the consumer. In the long run he will suffer, because this method violates a fundamental economic law, the law of supply and demand. The rigid rate base chained to the dollar is artificial and very dangerous.

If the rate base instead of being made rigid at an arbitrary point is allowed to move naturally with the price level and if prices are allowed to move up and down with other prices the dangers of overexpansion will be avoided. Cost of reproduction is a far safer rate base for the consumer than capital investment, because it will tend to check inflation, prevent overexpansion and keep the industry healthy.

---

## Hydro-Electric Development in China

A HYDRO-ELECTRIC generating station has recently been completed near Yunnan, in the southeastern part of China. The installation comprises two stations working in series, one with a head of 47 ft. and the other with 52 ft. Each is equipped with one 300-kva., 3,300-volt generator. The power is stepped up to 23,000 volts for transmission over a distance of about 20 miles.

*Mobile substation follows Southern trend toward automatic equipment*

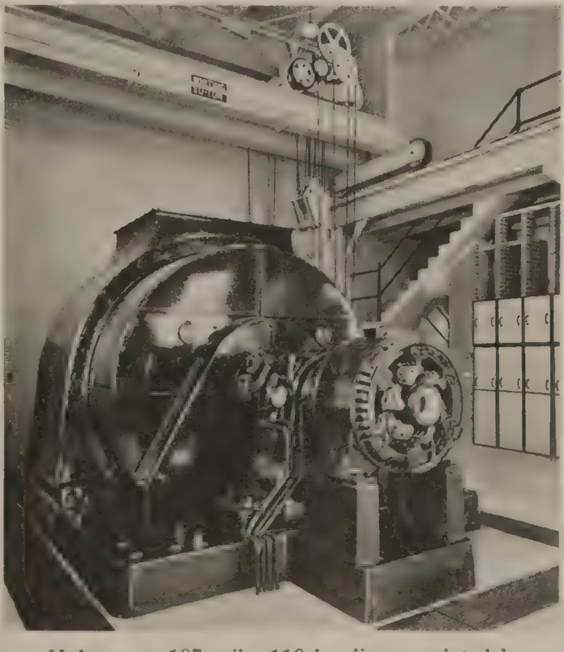
# Hydro Power on the Gulf Coast

Mobile, Ala., is second coast city to obtain power from streams of the South. Automatic operation of step-down substation with synchronous condenser described

By L. M. Smith and M. S. Merritt
*Engineering Department, Southeastern Engineering Company, Birmingham, Ala.*

"ON FRIDAY, Jan. 7, 1927, with appropriate public ceremony, hydro-electric power was ushered into the city of Mobile—Alabama's venerable and romantic 'City by the Sea.'" This brief statement of fact as read by the public in the daily press has in it, as every engineer knows, volumes of interesting but unchronicled studies, figures and experience that embrace between their inception and realization years of patience. The serving of Mobile, second city on the Gulf to receive hydro power, was no exception, and, if anything, more than the usual amount of study was necessary, as a glance at a map of southern Alabama would indicate.

For more than twelve months previous to the above-chronicled event engineering studies had been complete and construction crews had been at work on the 187-mile, 110-kv. transmission line between Mobile and the Lock 18 substation of the Alabama Power Company. For a somewhat shorter time construction work had been in progress on the new 18,000-kva. primary substation near Mobile and on the 22-kv. feeders radiating from it to serve a growing district of approximately 150,000 people.



*Voltage on 187-mile, 110-kv. line regulated by 10,000-kva. synchronous condenser*

Of the many various phases of this project that could be treated only one will be undertaken at this time—namely, a description of the operation of the automatic equipment in the substation at the receiving end. This substation, on account of its importance to such a large and growing district, far removed from the source of power supply, had to include in its make-up provision for voltage control of the long line as well as every practicable device available that would insure to the city the same quality of service to which its neighbors up state had been accustomed. The selection of equipment, particularly that involved in the automatic operation of the substation, was therefore made with especial care.

If frequent reference is made to the elementary and schematic relay diagrams given herewith, the operation of this automatic equipment can be more readily understood. All devices are shown in their normal or de-energized position and auxiliary switches and contacts are marked *a* if open and *b* if closed when in normal open or de-energized position. The elementary diagram is for the automatic features of the synchronous condenser only, whereas the schematic relay diagram shows in full the wiring for the protection of and for the automatic features of the entire station except the condenser. All devices are referred to by standard power club numbers used by the Alabama Power Company and are completely described in the accompanying table.

The purpose of this automatic switching equipment is to start the 10,000-kva., 11,000-volt synchronous condenser and connect it to the line if conditions warrant; to reclose automatically the four outgoing 22-kv. feeder breakers when they trip with normal conditions on the 22-kv. buses; and to protect against abnormal conditions that might cause serious trouble. The operation of the condenser is entirely automatic after the pull-button switch is closed to release the equipment for operation, and this switch remains in the closed position until it is opened manually to take the machine out of service.

The condenser is started as an induction motor on reduced voltage from a starting auto-transformer, the condenser field being short circuited through a resistance during the starting period. Just as the machine reaches synchronous speed and the exciter voltage builds up, the starting

* The prefix 1 to any device number indicates that the device is used on feeder equipment, and prefix 2 indicates its use on transformer equipment.

breakers are tripped and the running breaker is closed, connecting the condenser on full-line voltage. The short circuit is then removed from the condenser field and the field is connected direct to the exciter. The field resistance is then automatically adjusted to normal value and field current is applied as conditions warrant. If abnormal conditions arise at any time during the operation of the condenser, it will be shut down by some one or more of the protective devices described later.

The outgoing feeder breakers are first closed manually by pull-button control switches, and they may also be tripped by these switches. After automatic tripping of any of the feeders under normal conditions, the breaker will be reclosed three times and then locked out until the reclosing device for that breaker is reset manually, unless the breaker remains closed after one of the reclosures. In the latter case the reclosing device will reset automatically. This device for any breaker may be made inoperative at any time by opening a knife switch on the control panel.

With the foregoing explanation of the purpose of the automatic equipment a detailed description of the operations under normal and abnormal conditions will follow:

### Normal Operation

For normal operation, with all circuit breakers open and all protective devices reset, the 110-kv. line breaker is closed, energizing the 18,000-kva. transformer bank. Control switches 8 and 8*A* are then closed, energizing the 220-volt alternating-current control bus from the 2½-kva. power transformer 11, and the 125-volt direct-current control bus from the storage battery. If the alternating-current line voltage and frequency are normal, devices 27 and 95 close their *a* contacts and open their *b* contacts, and the condenser is ready to start.

The condenser is then released for automatic operation by closing pull-button switch 1. This energizes the coil of the master contactor, device 4, from the battery bus through the contacts of protective relays and *b* contacts of exciter relay 53 and running breaker 42, indicating that normal conditions exist, that there is no current in the field and that condenser is not connected to the line. Device 4 then closes its *a* contacts, energizing 27*A*; also 88, which starts the oil pressure pump for the condenser bearings; 88*X*, which starts to close its contacts; 48, which starts timing action, and 52*X*, which closes 52*Y*, which in turn closes 52. The closing of line breaker 52 makes a holding circuit for device 4, de-energizes 42*X* and 42*Y*, energizes condenser potential transformers and device 47. Voltage being normal, 6*AX* is energized through 47, *b* contacts of 6*A*, 40 and 42 closing 6*A*, which

## *Summary of Major Equipment Used in Mobile Step-Down Substation*

| Equipment | No. | Manufacturer | Type | Remarks |
|---|---|---|---|---|
| Power transformers | | | | |
| 6,000 kva., 110/22/11 kv. | 4 | Allis-Chalmers | O.I.W.C. | Capacity of each tertiary winding, 3,333 kva. |
| Station service transformer | | | | |
| 75 kva., 22 kv/230/115 volt | 3 | General Electric | O.I.S.C. | For station auxiliaries |
| Outdoor potential transformers | | | | |
| 500 va., 22 kv./110 volt | 1 | General Electric | O.I.S.C. | For regulator |
| 200 va., 22 kv./110 volt | 4 | General Electric | O.I.S.C. | For metering and synchronizing |
| Outdoor current transformers | | | | |
| 25-kv.-600/5 amp. | 2 | General Electric | K-202 | For metering |
| 110-kv. oil-circuit breakers | 1 | General Electric | FHKO-36-115B | Interrupting capacity 500,000 kva. |
| 25-kv. oil-circuit breakers | 7 | Westinghouse | O-221 | Interrupting capacity 455,000 kva. |
| 22-kv. lightning arresters | 4 | General Electric | Oxide Film | ........................................ |
| Synchronous condenser | | | | |
| 10,000 kva., 11 kv, three-phase, 60 cycle | 1 | Allis-Chalmers | ............... | Operates from tertiary of power transformers |
| Switchboard | | | | |
| 14 panel, 1½-in. slate | 1 | General Electric | 24x90 in. | Includes automatic equipment for condenser |
| Carrier current equipment | 1 | Westinghouse | ............... | 250 watt |
| Circulating-water pumps | | | | |
| 300 g.p.m. 70-ft. head | 2 | Allis-Chalmers | SH | For transformers and condenser |
| 110-kv. disconnecting switches | | | | |
| 400-amp. upright mounted | 1 | Southern States Equipment | VGL | For bypass on 110-kv. breaker |
| 400-amp. underhung mounted | 2 | Southern States Equipment | M | ........................................ |
| 22-kv. disconnecting switches | | | | |
| 400-amp. upright mounted | 24 | Southern States Equipment | "57" | Breaker disconnecting switches |
| 400-amp. horizontal mounted | 5 | Southern States Equipment | "57" | O. C. B. bypass switches |
| 22-kv. fuses | 14 | Schweitzer & Conrad | D | For potential and service transformers |
| Insulators | | | | |
| 110-kv. post | 27 | Jeffery-Dewitt | A-254; A-258 | 7 unit |
| 22-kv. post | 126 | Delta Star | DZO and ZDO | Post type |
| 11-kv. post | 43 | Delta Star | DK | Cat. No. 12590 |
| Disk insulators | 283 | Ohio Brass | No. 25622 | ........................................ |
| Traveling crane | 1 | Whiting | ............... | 30 ton |
| Storage battery | 1 | Electric Storage Battery Co. | MVJ-9 | 60 cells |

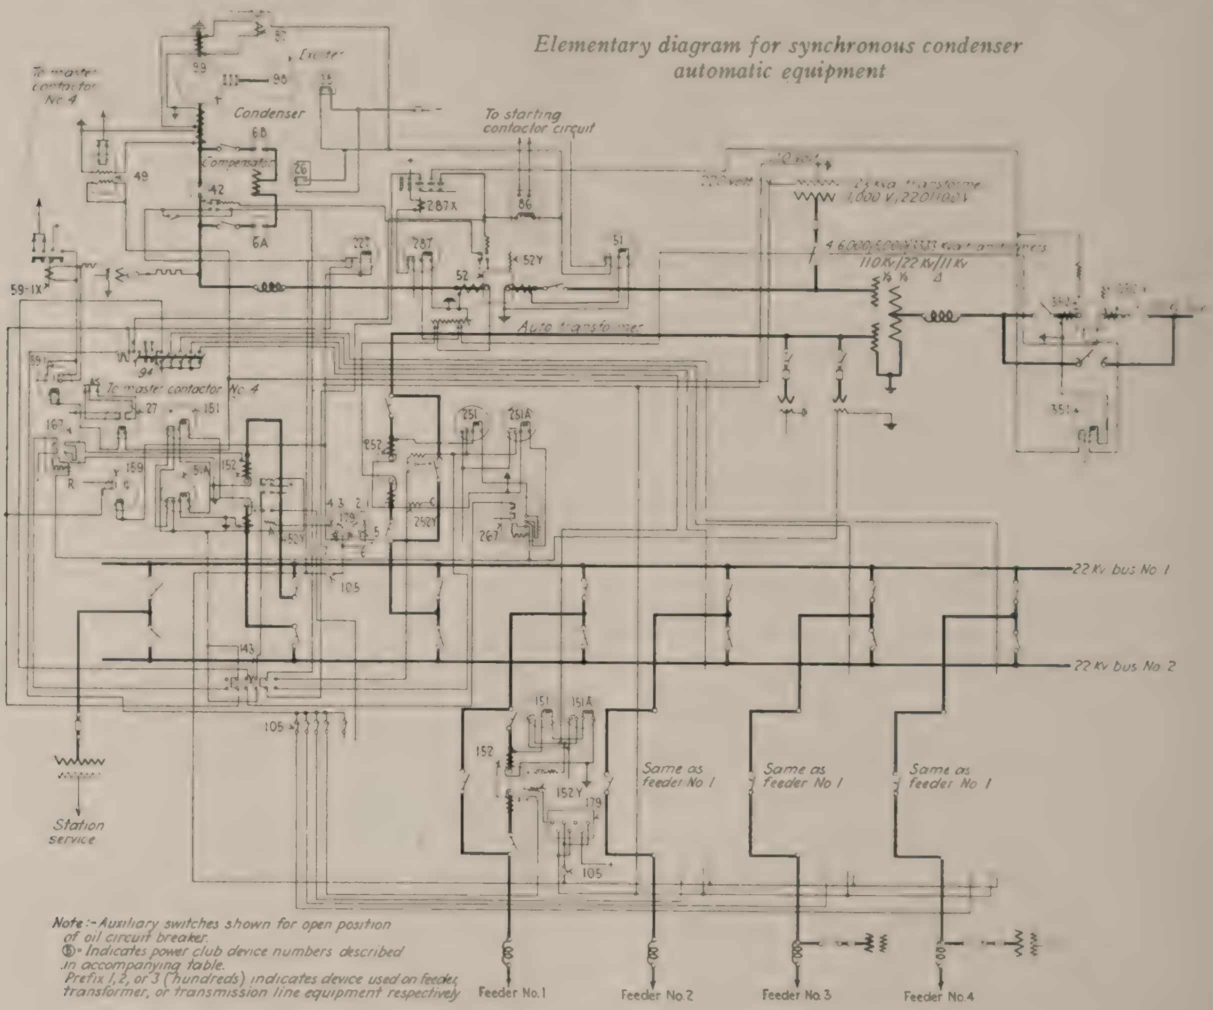
energizes the condenser-starting compensator. After a time delay 88*X* has closed its contacts, which energizes 6*BX* when 6*A* reaches its closed position, starting the condenser 99 to rotating.

The starting of 99 induces a heavy current in its field, causing synchronous speed device 13 to close its *a* contacts and closing the circuit to coil of 53 to the exciter leads. As 99 approaches synchronous speed the exciter voltage builds up to such extent as to operate the exciter relay and the current dies down in the field, allowing 13 to drop back, opening its *a* and closing its *b* contacts. The exciter relay 53 forms a holding circuit for its coil and with *b* contact of 13 energizes the coil of the field contactor 41. The closing of 41 removes the short-circuiting discharge resistor from the condenser field and connects the field to the exciter through high resistance, allowing sufficient current to flow to operate the field relay 40 with the aid of the potential winding. The closing of 40 breaks the closing circuit to breakers 6*A* and 6*B*, and closes timing relay 40*X*. The holding coil of 40*X* remains energized, but after a time delay opens its motor circuit and closes a circuit to the trip coils of 6*A* and 6*B*, and sets up closing circuit to the control relay 42*X*. When 6*A* and 6*B* trip, 42*X* is energized, closing the condenser running breaker 42, which connects the condenser on full-line voltage. Device 93 is then energized, which in turn closes its contacts, shunting out the high resistance in the field and allowing the voltage to build up to normal value. The condenser is now connected to the line and under the control of the voltage regulator, since the opening of the magnetizing breaker 6*A* closes the alternating-current potential circuit to the coil of regulator 90 through *b* contacts of 6*A*. If now the line voltage is too high, the contacts of 90 open, inserting resistance in the exciter field, which in turn decreases the condenser field, causing the condenser to operate at lagging power factor. Below a certain voltage the exciter operation becomes unstable, and to enable it to operate at a more efficient point direct-current undervoltage relay 80 drops out, closing its *a* contacts and closing circuit to the coils of 80*R*, which in turn operates the motor of the main field rheostat 70, cutting resistance into the condenser field, causing the condenser to operate at a still lower power factor. Regulator 90 then cuts resistance out of exciter field, allowing exciter voltage to return to a normal value. Device 80 then opens its *a* contacts, de-energizing 80*R*.

If the line voltage is too low, the regulator 90 increases the exciter field, causing the condenser to operate at leading power factor. If the exciter voltage should become too high, undervoltage relay 80 closes its *b* contact, energizing 80*L*, causing the motor-operated rheostat to decrease the resistance in the condenser field. The regulator 90 then brings exciter voltage down to normal, and 80 opens its *b* contact, de-energizing 80*L*.

With the condenser now on the line and the 22-kv. bus voltage normal, the control switches for the four feeder breakers are operated manually, closing these breakers, 152, through a circuit to 152*Y*. The control switches also set up circuits to the four reclosing relays 179, which circuits remain made until the control switches are operated to the trip position.

*Elementary diagram for synchronous condenser automatic equipment*



*Note:—Auxiliary switches shown for open position of oil circuit breaker.*
*⑤—Indicates power club device numbers described in accompanying table.*
*Prefix 1, 2, or 3 (hundreds) indicates device used on feeder, transformer, or transmission line equipment respectively*

## Abnormal Operation

This automatic equipment provides protection against abnormal operations, which are divided into two classes:

1. Transient troubles for which the condenser is shut down temporarily and prevented from restarting until normal conditions are restored:
    - (*a*) Undervoltage on bus.
    - (*b*) Overvoltage on bus.
    - (*c*) Reverse power through the transformer bank.
    - (*d*) Overheating of stator windings.
    - (*e*) Underfrequency.
    - (*f*) Overload on feeders.
2. Serious troubles which prevent resumption of opera-

tion until equipment is inspected and devices reset by hand:

(*a*) Failure of transformer windings.
(*b*) Failure of condenser windings.
(*c*) Overheating of condenser bearings.
(*d*) Incomplete start of condenser.
(*e*) Overheating of starting compensator.
(*f*) Overload on the condenser.

These operations will now be described in more detail.

### TEMPORARY SHUTDOWNS

*Undervoltage.*—With undervoltage on the alternating-current bus, relay 227 closes its *a* contacts, closing the circuit to the coil of tripping contactor 94, which in turn trips breakers 52, 152 and the bus tie breaker if the latter is operating as a feeder breaker. Upon tripping of these breakers by relay 227, relay 27 opens its *a* contact, which prevents the condenser restarting until normal voltage is restored. When this occurs, 27 closes its *a* contact, starting the condenser, which, as previously described, is then connected direct to the line by breaker 42. Reclosing relays 179 then close feeder breakers 152, also the bus tie breaker if operating as a feeder breaker.

*Overvoltage.*—If excessive voltage conditions occur with the condenser in operation, overvoltage relay 159 closes its contact, energizing contactor 94, which trips the feeder breakers and 52. At the same time 59-1 closes its *a* contact and opens its *b* contacts, energizing coils of 59*X*-1, which shunts out coil of 4 and holds it out until normal voltage is restored. When this occurs, 59-1 closes its *b* contact, allowing 59-*X*-1 to open its *a* contact so that the condenser restarts and the feeder breakers 152 reclose directly after the condenser is connected to the line.

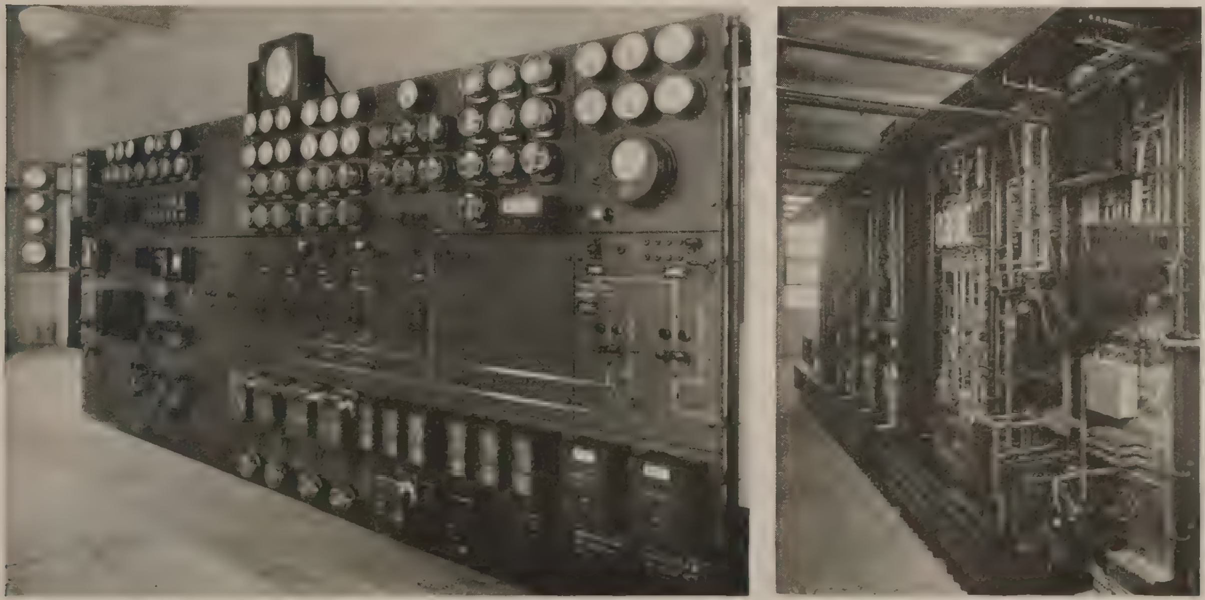
*Reverse Power.*—When any of the feeders are connected to the local steam plant and that plant is generating, the reclosing features of 152 are made inoperative by opening a knife switch on the front of the switchboard. For trouble on the 110-kv. line the steam plant contributes to the trouble and causes reverse power to flow through breaker 252. This reversal of power causes relay 267 to operate, energizing the coil of 94, which trips the 22-kv. feeder breakers and the condenser breaker. When alternating-current voltage is restored on the transformer bank, the condenser restarts automatically, but the feeders must be synchronized by hand, as the reclosing scheme is inoperative due to the operation of the steam plant.

*Overheating of Stator Windings.*—For the protection of the stator windings against overheating, thermal relay 49 contains an element with the same heating characteristics as stator windings, so that when current flowing through these windings reaches an excessive value and continues for a period sufficient to cause overheating, 49 opens its *b* contacts, which de-energizes 4 and holds it out until the thermal element has cooled to such a value as to allow its *b* contacts to close again. Tripping or opening of the *b* contacts also causes the annunciator to operate.

*Starting auto-transformer for 10,000-kva. synchronous condenser*

*Underfrequency.*—When the system frequency drops to 5 per cent below normal, relay 95 closes its *b* contacts and opens its *a* contact, the former shunting out coil of 4 and operating the annunciator; 4 prevents restarting the condenser until the frequency is restored to normal.

*Overload on Feeders.*—Should an overload develop on any feeder, its breaker opens due to action of overcurrent relay 151 or ground relay 151*A*. The *b* auxiliary switch of breaker 152 then closes a circuit to 179*X*, which completes the circuit to the release coil of reclosing relay 179, which allows its armature to rotate. After one minute the first arm of this relay closes its front contact, closing an auxiliary relay, which seals itself in. The back contact is then closed by the first arm, which recloses breaker 152 through 152*Y*. If 152 remains closed, the operating disk of 179 makes a complete revolution and resets itself for a new cycle, but if the breaker reopens within one minute, the second arm of 179 repeats the action of the first arm. If the feeder is still subjected to overload, 152 again trips and is reclosed for a third time by the third and last arm of 179. If after the third reclosure overload still persists, 152 again trips and closes its *b* switch. In this case there will be no reclosure, for after one revolution of the disk of 179, if the release coil is still energized, a stop arm engages the disk and holds it in the lock-out



*The switchboard in Mobile substation is compact and neat, as indicated in front and rear views* position until 179 is reset by hand. If, however, 152 remains closed after either the second or the third reclosure, 179 returns to the reset position ready to begin a new cycle.

### Permanent Shutdowns

*Failure of Transformer Windings.*—Upon failure of the power transformer windings a differential current flows in the leads from the high-tension and low-tension windings, causing relay 287 to close its contacts, operating 287*X*, which trips breakers 252, 352 and 52 and operates relay 86, locking out the condenser and giving an alarm to the operator.

*Failure of Condenser Windings.*—Failure of the condenser windings causes a differential current to flow between the condenser bus and the neutral leads. This current operates machine differential relay 87, which closes its *a* contact, tripping breaker 52 through lock-out relay 86 and giving an alarm through annunciator 30.

*Overheating of Bearings.*—Overheating of the condenser bearings causes the dial type thermometer 38 to close its contacts, which are set at the maximum safe operating temperature. Closing of these contacts operates 86 to trip 52 and to give an alarm through 30.

*Incomplete Starting.*—When the starting sequence is initiated, the magnetizing breaker 6*A* closes, energizing the starting protective relay 48, which starts a timing action. If after a definite time delay sufficient for the machine to come up to speed and be connected direct to line the *b* contact of 93 has not opened, deenergizing 48 and stopping the timing action, the delay contact closes, operating 86 to trip and lock out 52 and give alarm.

*Field Failure.*—Two methods are provided for shutting down the condenser in case its excitation is lost. With high alternating-current voltage loss of excitation causes relay 59-2 to operate through interlocks on 42 and 4 so that, if excessive voltage exists on the bus with machine in running position and exciter potential fails, 59-2 operates 86 to trip and lock out 52 and give an alarm.

With low alternating-current voltage loss of excitation with the machine in the running position causes 27*A* to be energized from the alternating-current bus through the *a* contact of 4. If the alternating-current voltage is low, allowing 27*A* to close its *a* contacts and the field current to drop low enough to allow the *b* contact of field relay 40 to close its *b* contact, a circuit is completed through these contacts and the *a* contacts of 4 and 42 operating relay 86 to trip and lock out 52 and give an alarm.

*Overheating of Compensator.*—With overheating of the starting compensator, the liquid in bulb of thermal relay 26, which is inserted in the compensator, expands with an increase in temperature, closing the relay contacts, operating 86 to trip and lock out 52.

*Condenser Overload.*—When an overload occurs on the condenser, overcurrent relay 51 operates 86 to trip and lock out 52.

Each and every one of the foregoing conditions was carefully worked out between the engineers of the company and the engineers of the General Electric Company, with the result that perfect operation resulted during the six months that the equipment has been in service.

## Operating Experience With Rectifiers

RESULTS obtained by the Chicago, North Shore & Milwaukee Railroad in operating mercury-arc rectifiers are presented below. Most of the data cover an entire year's experience and were presented by Caesar Antoniono, electrical engineer of the company, at the Chicago meeting of the A.I.E.E.

*Table I—Performance of rectifier and synchronous converter substations*

The kilowatt and efficiency values do not include the power used for the operation of automatic devices in auxiliaries such as vacuum pump, water pump, motor-generator set and heaters in the rectifier station nor the power used for auxiliaries and alternating-current contactors in the converter stations

### Relations between transformer spacing, energy loss and voltage drop developed for equations of economical transformer and conductor sizes

By W. R. Bullard
*Electric Bond & Share Company, New York City*

IN CONSIDERING the characteristics of the secondary distribution system, where the conductors are arranged in straight line feeds without branches, the well-known relations between transformer spacing, energy loss and voltage drop are used in the development of simplified equations which can be used in determining economical transformer and conductor sizes to fit any given set of local conditions.

## Secondary System

Much has been written concerning the comparative merits of various voltage combinations in secondary distribution systems, such as three-wire single-phase for lighting, separate three-wire three-phase for power, four-wire three-phase for power and lighting, etc.

Therefore in this article no comparison is made between the different types of systems. However, in so far as possible, the methods and formulas have been made sufficiently general to apply to all the usual types of secondary systems.

*General Scheme of Design.*—As mentioned previously, there are two types of loads that should be considered separately in the design of the distribution system—namely, the general distributed load of the system as a whole, and individual loads of large sizes. Loads of the latter type are usually served individually by special transformer banks not connected to the secondary mains, or else by transformers of extra large size connected to the secondary mains, but located immediately adjacent to the concentrated load which they serve. Thus in designing the secondary system large concentrated loads need not be considered in connection with the selection of copper sizes, etc., since in general the current of these loads does not pass through the secondary mains.

In the selection of copper sizes and transformer sizes for the distribution system, exact calculations of the economics are not practicable, due to a number of indeterminate factors and to the fact that the exact characteristics and distribution of the load cannot be conveniently determined either for the present or for the future. However, by making a reasonable number of simplifying assumptions and by considering average conditions in different sections of the system, average sizes can be established for low-voltage copper and distribution transformers to serve the load economically.

In establishing average characteristics of the load it is, of course, not permissible to consider the entire system in one set of calculations unless the system should be comparatively small or unless conditions should be comparatively uniform throughout. However, in most cases it is possible to select a few sections of territory in any given system throughout each of which all the determining factors will be fairly uniform. In a medium-sized town, for instance, there is usually a business section where the load is fairly concentrated and of certain particular characteristics; a high-class residential district in which the load characteristics are different from those in the business section, but nevertheless fairly uniform, and a poorer class of residential section in which the load characteristics are different from those of the two other sections.

## Size of Transformers and Conductors

A practical procedure for establishing proper sizes of transformers and secondary copper in average distribution systems is to consider separately each of two or three different districts, such as those mentioned, and to make complete calculations in each case to fix the proper characteristics.

The calculations should be based on load conditions that will exist several years in the future. Thus if transformer sizes and copper sizes determined from the method that is to be described are adopted immediately, these sizes will be somewhat larger than those theoretically correct for existing conditions, but the proper economics will be approached during the growth of load for several years until the most economical point is reached, after which the cost will again gradually exceed the theoretical minimum, but at no time during a number of years of system growth will the over-all cost be greatly different from the theoretical minimum.

After the proper copper sizes have been determined, these sizes will of course be used for extensions and replacements of secondary mains in the particular sections to which the different sizes apply. The transformer sizes determined by the economics will, of course, be used in average cases in the particular sections to which they apply, although a small proportion of other sizes can be used when required. After a number of years have passed it is, of course, desirable to make a new study of the system economics and revise the values previously obtained. The new values can then be used for extensions and replacements of the old system.

---

**The first article of this series appeared in* Electrical World *March 10, 1928. The third article will be published in an early issue.*

If, instead of increasing the transformer sizes with the growth of load, as is frequently done in the operation of distribution systems, the economical size of transformers be adhered to in all average cases and the growth of load be handled by setting new transformers of the same size at intermediate points between the old transformers, the growth of load can be handled indefinitely with the same secondary copper and with a gradually decreasing voltage drop and decreasing percentage of secondary copper loss.

It is not necessary, of course, to have a decreasing voltage drop or copper loss if the design of the system has fixed the proper values of these quantities at the start. In some measure, therefore, it is desirable to use at the start transformers somewhat smaller than those indicated by the calculations, gradually increasing the size until after a number of years, these sizes may be somewhat larger than the values indicated by the study. The tendency should be, however, toward the establishment of a more or less fixed standard of sizes and toward handling the growth of load by setting new transformers rather than replacing old transformers with new ones of larger size.

### STRAIGHT LINE FEEDS

In the following discussion the term "network feed" is used to indicate that each transformer feeds a portion of a system the secondary mains of which have a network arrangement formed by intersecting streets. The portions served by individual transformers may either be separated from each other, as in the case of a radial system, or may be interconnected to form a large network, as in the case of the so-called low-voltage multiple-feed network system.

The laws governing voltage drop and power loss in a circuit consisting of a single line without branches are well known. Where the low-voltage system consists of such a line, the load being uniformly distributed and the transformers being of equal size and uniform spacing, both the voltage drop and power loss are inversely proportional to the square of the number of transformers or directly proportional to the square of the size of each transformer.

Let $I_T$ equal the load current per leg of the transformer; $a$ equal the area of cross-section of each conductor of secondary mains in units of 1,000 circ.mil; $V$ equal the maximum voltage drop per conductor in volts; $W$ equal power loss in kilowatts per 100 ft. of single conductor; $D$ equal load density in amperes per conductor per 100 ft. of circuit. Then, if each transformer feeds current equally in each direction in the secondary mains,

$$V = \frac{0.137\, I_T^2}{Da}$$

$$W = \frac{0.0915\, I_T^2}{1{,}000\, a}$$

These two equations give volts drop and power loss per conductor in terms of the load at each transformer, load density and cross-section of copper.

In practice it is not always possible to have the transformers so spaced that the load will be equally divided between them, nor for any given section of secondary mains is it always possible to have the transformer in the exact center of the load. Therefore, due to these difficulties and due to variations in load density and variations in other system characteristics, the values of voltage drop and power loss would in practice be considerably higher than those given by the above equations.

In order to make the equations applicable to average conditions of practice in the majority of small- and medium-sized systems, the values of voltage drop and power loss should be increased about 100 per cent, which gives

$$V = \frac{0.274\, I_T^2}{Da} \qquad (1)$$

$$W = \frac{0.183\, I_T^2}{1{,}000\, a} \qquad (2)$$

The value of 100 per cent may seem at first sight to be a large proportionate increase in the constants of the equations to care for departures in practice from balanced and uniform conditions. However, when it is realized that an off-center spacing of only 25 per cent of the total length of line served by one transformer (three times as much load in one direction as in the other) will give 225 per cent of the theoretical voltage drop and 175 per cent of the theoretical power loss for perfectly balanced conditions, it can be seen that the increase of 100 per cent is a reasonable allowance for average systems in which it is not possible to maintain specialized organizations constantly to check and correct unbalanced conditions. Whereas the effect of the transformer being off center is to increase the voltage drop more than the power loss, the effect of the load being non-uniformly distributed is to increase the power loss more than the voltage drop. In practice, therefore, there is likely to be a similar increase of both quantities.

In large, thoroughly organized systems it will usually be possible to hold the values nearer to those corresponding to ideal conditions. The application of the equations given in this article to a case of this kind can be very easily corrected by increasing the value of the allowable voltage drop and decreasing the estimated unit cost of energy loss before these values are inserted in the equations. Probably in the largest and best organized systems an allowance of 50 per cent instead of 100 per cent could be made in deriving equations 1 and 2. In this case, to make the equations of economics given in the last part of this series applicable, the allowable voltage drop as estimated from service conditions should be multiplied by the factor $\frac{4}{3}$ and the unit cost of copper losses where applied to secondary mains should be multiplied by the factor $\frac{3}{4}$.

The equation for voltage drop is calculated on the basis of resistance drop only. However, in usual types of distribution systems, the power factor at the peak of the load is high, due to the high percentage of lighting load. Therefore the maximum voltage drop will usually only slightly exceed the theoretical values calculated for resistance only. A small amount of additional voltage drop due to the effect of the line reactance will usually be taken care of by the factor of safety used in equation 1.

Where the conductors are small and are spaced reasonably close together, the resistance is usually the dominating part of the impedance. Where the conductors are large and are separated by an appreciable distance, as for instance in the case of large single-conductor underground cables located in separate ducts, the reactance may be the dominating part of the impedance. In such cases, if the power factor of the load happens to be low, appreciable errors may be introduced into the calculations of economics by the fact that reactance has been neglected. However, even in such cases, the equations may be used to obtain a first approximation to the correct results, the figures obtained being then checked by actual calculation of voltage drop. If the error is shown to be appreciable by this method, very nearly correct results can be obtained by making a second set of calculations, using a value for allowable voltage drop, less than the actual value in proportion to the amount that the allowable value has been exceeded by the results of the first set of calculations.

*Economical Transformer Spacing and Copper Size.*—Upon applying certain simplifying processes the calculation of economical transformer spacing and copper size become a comparatively simple matter by the use of the above equations for power loss and voltage drop. Take first the case of a simple straight line circuit. Factors that enter into the calculations of economics are, cost of power loss in transformers and fixed charges on transformer investment, cost of power loss in secondary mains and fixed charges on investment in secondary copper.

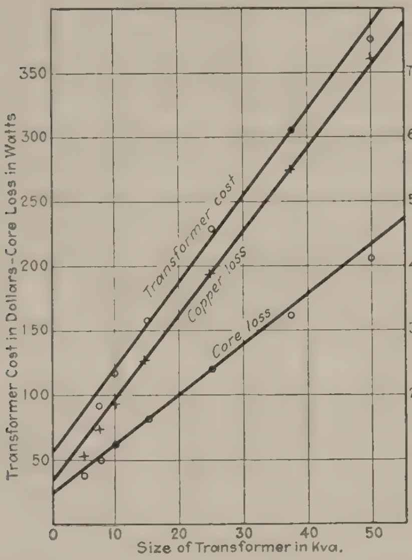

*Fig. 1—Cost and losses of 2,300-volt distribution transformers, single phase, 60 cycle*

If the investment costs of transformers are plotted against transformer sizes, the result is approximately a straight line for a limited range of transformer sizes. (See Fig. 1.) The point where this line cuts the axis of cost represents a cost that applies to each transformer regardless of its capacity. The slope of the line represents the cost per kilovolt-ampere capacity for any given number of transformers. Since the kilovolt-ampere capacity of any given system is fixed, this latter cost is fixed and therefore has no effect in determining the economics of transformer spacing. The fixed cost per transformer mentioned above, however, is a very useful quantity. If we take this cost and add to it the cost of installation, including auxiliary devices such as fuses, lightning arresters, ground connections, etc. (in the case of an underground system the cost of the transformer vault would be included), the result is a total fixed cost per transformer installation. This multiplied by a percentage figure to reduce it to fixed charges per annum gives an expression that can be used directly in computing the economics.

To this quantity, however, should be added the yearly cost of the fixed part of transformer losses. The latter can be obtained in the same manner as above by plotting losses against size of transformer (see Fig. 1) and using the values where the lines cut the axis of losses. In plotting the copper loss curve of Fig. 1 the values should correspond to the transformer loading that will be used in practice. For instance, if in order to obtain good economy it is desired to load transformers on the average of, say, 115 per cent of their rating at the system peak load, then the copper loss at 115 per cent load should be used in plotting the copper loss curve. In order to obtain the annual cost of core loss it is necessary to multiply by the total number of hours in the year, whereas in the case of copper loss the annual duration factor previously described must be used.

Let $C_1$ equal total yearly transformer costs per installation exclusive of the costs which vary with the size of transformer; $W_1$ equal copper loss in kilowatts per transformer installation taken from curves similar to those in Fig. 1; $W_2$ equal core loss in kilowatts per transformer installation; $C$ equal cost of copper loss in dollars per kilowatt-hour; $C_4$ equal the cost of core loss in dollars per kilowatt-hour; $C_5$ equal fixed charges on cost of each transformer installation including the intersecting point of the cost curve in Fig. 1 and investment in auxiliary apparatus per transformer installation. Then

$$C_1 = W_1 f C + 8760 W_2 C_4 + C_5 \qquad (3)$$

In deriving the value of $f$ for equation 3 in the case of automatic network systems where circuits may be taken out of service at periodical intervals, the actual load curves for the transformer should, of course, for accuracy be considered instead of the load curve of the whole system. This also applies to all the calculations that involve loss and voltage drop in the secondary mains. However, in cases where the system load factor is high, the practice of taking circuits out of service during light load periods has very little effect on the total losses, since the decrease in core loss is offset to a great extent by the increase in copper loss due to longer distances of feed. In such cases it is permissible to use the duration factor of the system load.

Since the number of transformers per 100 ft. of secondary circuit is represented by the expression $\frac{D}{I_T}$, we have for that portion of the yearly transformer cost per 100 ft. of secondary circuit which varies with the transformer spacing, the expression $\frac{C_1 D}{I_T}$.

In the case of the yearly cost of secondary copper, the portion of the cost that affects the economics is that portion which varies with the size of copper. For overhead systems this can be derived approximately from the cost per pound of copper delivered to the job. The remainder of the cost of overhead lines, including poles, hardware and insulators, is very nearly independent of the size of copper and therefore does not enter into the problem of economics. For underground systems a graph such as that given in the first of this series of articles, which appeared in ELECTRICAL WORLD, issue of March 10, page 501, should be used, only the slope of the straight line being taken and the fixed cost, represented by the intersection with the vertical axis, being excluded from consideration.

Let $C_2$ equal annual fixed charges on investment in secondary copper in dollars per year per 1,000 circ.mils per 100 ft. of single conductor, exclusive of installation costs and including only that portion of the cost that is directly proportional to the size of conductor. Let $n$ equal the number of current-carrying conductors in the secondary mains and $n_1$ equal the total number of conductors in the secondary mains including the neutral (neutral being the same size as the other conductors); then we have from equation 2 the total variable portion of the yearly cost of secondary mains (including losses) per 100 ft. of system equal to

$$\frac{0.183\, nfC\, I_T^2}{1{,}000a} + C_2 n_1 a \qquad \textit{(Formula a)}$$

where $a$ is the conductor cross-section in thousands of circ.mils. The first term of this expression represents the annual cost of losses, and the second term represents the annual fixed charges on investment. Differentiating this formula with respect to $a$ and equating to zero, we have

$$a = 0.01352\, I_T\sqrt{\frac{nfC}{n_1C_2}} \qquad (4)$$

This expression gives the economical size of copper in terms of load current at the transformer, number of conductors, cost of copper loss, fixed charges on investment and duration factor.

Inserting this value of $a$ in the above expression for total variable annual costs of secondary mains per 100 ft. of circuit (formula $a$), we have

$$0.02704\, I_T\sqrt{nn_1fCC_2}$$

The variable portion of the total annual cost of the whole system of 100 ft. of secondary circuit is then

$$0.02704\, I_T\sqrt{nn_1fCC_2} + \frac{C_1D}{I_T}$$

the last term being the variable portion of the annual transformer costs. Differentiating this expression with respect to $I_T$ and equating to zero, we have

$$I_T = \frac{6.08\sqrt{C_1D}}{(nn_1fCC_2)^{1/4}} \qquad (5)$$

Equations 4 and 5 give the economical size of copper and economical load at the transformer in terms of load density and the various other factors that enter into the problem. These equations are expressions for the complete economics of copper size and transformer spacing, where these quantities can be considered independent of voltage drop or current-carrying capacity of copper. Although equation 5 does not directly express the average size of transformer that should be used in practice, the latter can be easily determined from the load current $I_T$ by applying whatever factor of safety it is desired to use in the loading of transformers. This is a matter of judgment, depending upon the amount of supervision that can be maintained over the transformer loading. In general, it may be said, however, that for good economics the transformers should be loaded to safety limits.

In any given set of calculations equations 4 and 5 should be used first. After numerical values are obtained by means of them the results should then be tested to determine whether the allowable voltage drop or current-carrying capacity would be exceeded by the use of the values thus obtained. Voltage drop can be determined by the use of equation 1. The matter of current-carrying capacity is of course a question of comparing the size of copper obtained from equation 4 with one-half of the value of current $I_T$ obtained from equation 5.

Allowable voltage drop is primarily a matter of quality of service and must be determined by judgment based on operation experience. The direct result of poor voltage is the ill will of the customer but not always a physically decreased energy consumption. Attempts have been made to evaluate mathematically the loss in revenue due to decreased energy consumption caused physically by low voltage at the customer's service. However, the fallacy of such procedure is easily seen, since in the long run a certain percentage of customers will manage somehow to obtain the amount of light or power they require. If their lighting is poor due to low voltage and their complaints to the power company are ignored, they will use bulbs of lower voltage rating or higher wattage, thus bringing their power consumption equal to or above what it would be if the voltage were normal. Furthermore, in systems having primary feeder regulators of sufficient range the average service voltage can be held normal, regardless of the drop in secondary mains. In such cases the voltage drop in secondary copper can have little or no direct effect on power consumption.

The above is not intended to convey the impression that power consumption is entirely independent of the voltage regulation, but merely that there is no direct mathematical relation between the two. It is quite a common occurrence in the reconstruction of old distribution systems to have the improvement in voltage regulation bring about a noticeable increase in power consumption. However, there is usually no convenient means of determining how much of the increase is the direct result of the voltage improvement and how much is due to the increased use of energy in appliances, etc., by some of the customers resulting from the improved quality of service. At any rate there is usually little to be lost and much to be gained by providing service of high quality, and, as previously stated, the exact degree of this quality must be determined by judgment based upon experience.

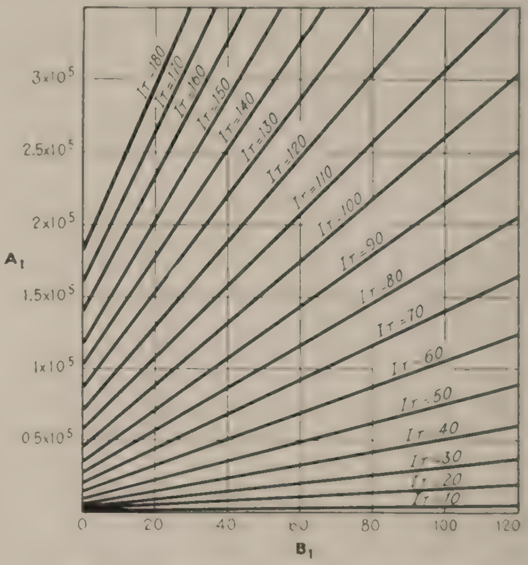

*Fig. 2—Economical load at transformer (Equation 9)*

In systems having no voltage regulators the entire voltage drop between station bus and customer's service must be taken into consideration in determining the allowable voltage drop in secondary mains. However, in systems equipped with feeder regulators the voltage at services nearest to the transformers can be maintained at values slightly above normal, allowing that at services farthest from transformers to fall slightly below normal. The maximum variation from normal voltage is then only approximately one-half the maximum voltage drop in the secondary mains. This is based on the assumption that the voltage drop in primary laterals is small enough to be neglected, which is quite often the case, as mentioned in the discussion of the primary system. Thus in many systems equipped with regulators a maximum secondary voltage drop of 4 per cent is probably a reasonable allowance, giving a variation from normal at the customer's service of approximately 2 per cent.

By normal voltage is here meant an average voltage slightly higher than the rated voltage of the lamps, since an allowance must be made for voltage drop in the customer's wiring.

If the allowable voltage drop would be exceeded by the use of values obtained from equations 4 and 5, then a new set of calculations must be made considering voltage drop as the limiting factor. An equation for this condition is obtained by inserting the value of *a* from equation 1, or

$$a = \frac{0.274\, I_T^2}{DV} \tag{6}$$

in formula *a* and adding the expression for yearly transformer costs. This gives a total variable annual system cost of

$$\frac{0.183\, DVnfC}{1{,}000 \times 0.274} + \frac{0.274\, C_2 n_1 I_T^2}{DV} + \frac{C_1 D}{I_T}$$

Differentiating and equating to zero, we get

$$I_T = 1.221 \sqrt[3]{\frac{C_1 V D^2}{C_2 n_1}} \tag{7}$$

If current-carrying capacity is the limiting factor, then the value of *a* in terms of its current-carrying capacity must be inserted in formula *a*. For overhead conductors the current-carrying capacity is very nearly proportional to the three-fourths power of cross-sectional area (see any good table of carrying capacities of copper wire), whereas for underground conductors this relation is roughly according to the square root of the cross-sectional area instead of the three-fourths power. (See paper by Donald M. Simons, *Journal A. I. E. E.*, May, 1923.) The occurrence in underground systems of a straight line feed is unusual; therefore it can be assumed that equations for straight line feeds are applicable mainly to overhead systems.

Let *b* equal the size in 1,000 circ.mil required to carry 100 amp. Then

$$a = \frac{I_T^{4/3} b}{1170} \tag{8}$$

Inserting this value in formula *a* and adding the expression for transformer cost, we have a total variable annual system cost of

$$\frac{0.214\, nfC}{b} I_T^{2/3} + \frac{C_2 n_1 b}{1170} I_T^{4/3} + \frac{C_1 D}{I_T}$$

and repeating the process of differentiating, we get an equation of the form

$$A_1 = I_T^{7/3} + B_1 I_T^{5/3} \tag{9}$$

where
$$A_1 = \frac{878\, C_1 D}{C_2 n_1 b} \tag{10}$$

and
$$B_1 = \frac{125.2\, nfC}{C_2 n_1 b^2} \tag{11}$$

Equation 9 gives the economical load at the transformer in terms of the various factors that enter into the problem. It has a somewhat complex analytical solution. Therefore, to facilitate its use, the values involved have been plotted as shown in Fig. 2. From this figure the required value of $I_T$ can be found by locating the point the co-ordinates of which are the numerical values of $A_1$ and $B_1$, then interpolating between the values of $I_T$ represented by the straight lines of the figure.

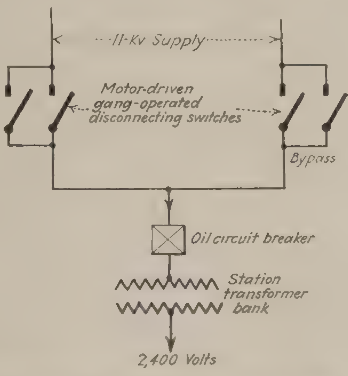
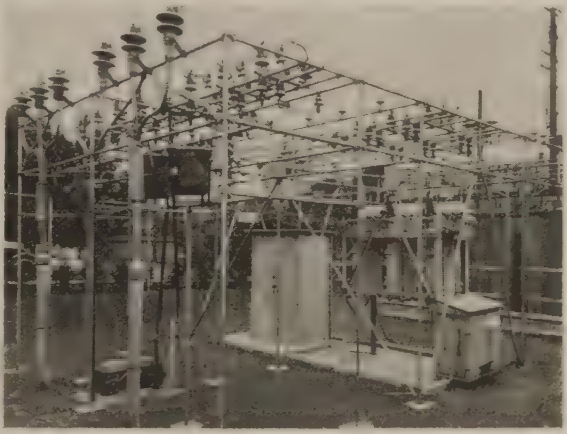
# Line-Transfer Scheme Uses Only One Circuit Breaker

By E. F. Pearson
*Electrical Engineer Northwestern Electric Company, Portland, Ore.*

Automatic selective transfer equipment is employed by the Northwestern Electric Company in substations to permit using a single 11-kv. breaker for handling two incoming supply lines to each station. Through the elimination of one heavy-duty breaker an over-all saving of approximately $3,000 per station is effected. Motor-driven air-break disconnecting switches automatically transfer a selected 11-kv. line to the circuit breaker. Connections are shown in the diagram.



*A single oil-circuit-breaker is used in this line-transfer arrangement. The disconnecting switches are motor operated*



In case of trouble on the line from which the station is operating, the sequence of operation is as follows: Relays open the oil circuit breaker, which breaks the load in case the station is not already dead. The motor-driven, gang-operated, interlocked air-break switches then transfer the oil breaker to the other line and the breaker closes and picks up the load. The complete switching operation takes place in five seconds. In case the second line is also in trouble the station will not be transferred, but will take service from the first line to be restored to normal.

The station may be transferred from one line to the other, if desired, without dropping the load by the manually operated by-pass disconnecting switches. In addition to the automatic transfer equipment the oil breaker is also controlled through a periodic-reclosing relay operating on station overload. In case of extreme overload the breaker will open and close twice, at predetermined intervals, and lock out if the trouble still exists after the last reclosure.

All motors and relays are operated with 120 and 240 volts alternating current, while release coils and circuit-breaker trip coils operate at twelve volts direct current.

To date, the first station equipped with this apparatus has transferred circuits three times during emergencies. A check on customers' equipment subsequent to the outages showed that a number of motor-driven ice machines of the meat-market type remained on the line after the transfer was made. This indicates that, in general, ice machines will resume service if the outage is five seconds or less.

## Indirect Costs on Transmission Projects

By M. J. Idail

*Electrical Engineer for F. R. Weller, Consulting Engineer, Washington, D. C.*

Careful cost records kept during the past five years on four large transmission projects show a good uniformity in the relation that the total indirect (or overhead) cost bears to the total cost. The projects studied covered widely different conditions, were for different clients, were handled with different types of construction organization and included tower lines, pole lines and large and small substations. The total cost of the largest project was $3,400,000, the smallest $500,000. Progress rates of the various jobs were such that the average rate of expenditure of money ranged from $170,000 per month to $50,000 per month.

INDIRECT COSTS INVOLVED IN TRANSMISSION-LINE AND SUB-STATION CONSTRUCTION IN TERMS OF PER CENT OF DIRECT COST*

| | Per Cent |
|---|---|
| Injuries and damages (compensation and liability insurance) | 1.0 |
| Other insurance (not including car or truck insurance) | 0.25 |
| Preliminary engineering investigation | 0.25 |
| Home office engineering and superintendence (studies, designs, supervision of construction; costs of engineering, purchasing, general accounting and treasury and legal departments) | 3.75 |
| Field engineering and superintendence (construction superintendent; general foremen; field engineering other than surveys) | 2.50 |
| Field office and storeroom (bookkeeping and cost keeping; disbursements; material receipt and issuance; field purchases of material) | 2.00 |
| Engineering fee and contractor's profit (including fees for home office purchasing, general accounting, treasury, etc., departments) | 12.50 |
| Interest during construction | 4.50 |
| | 26.75 |

* 26.75 per cent of direct cost is equivalent to 21.4 per cent of total cost

The accompanying table represents the average experience on the projects above outlined and is adjusted for differences in accounting practice. It goes without saying that differences in conditions and accounting practices may cause the reported indirect costs on other projects to be appreciably greater or less than those here given.

In preparing estimates of cost there is a tendency to fail to evaluate justly certain items which are on the border line between direct and indirect costs, to regard such costs as being cared for in the indirect cost allowance, and then to fail to make the indirect allowance sufficiently large. In actual cost keeping, many such items are easily evaluated and are charged to direct cost accounts, and to this extent the actual costs of the direct accounts exceed the estimated allowances. Examples of such items are depreciation on cars, trucks, camp equipment, office equipment, etc.; losses sustained by reason of camp not being self-supporting; local attorneys' fees and title abstract work in connection with easements on land. Field office drafting should be a direct charge against the land account. Truck and car operation, expense accounts of survey party chiefs, sub-foremen, the chief locating engineer, right-of-way men, etc., are direct rather than indirect costs.

## Employees Average 225 Lamps in Pittsburgh Campaign

A six weeks lamp sales campaign, undertaken in an effort to fill the empty light sockets throughout the territory of the Duquesne Light Company, was recently completed with sales averaging 225 lamps per salesman. A total of 116,739 lamps was disposed of by the 520 employees who took an active part in this work.

A preliminary estimate, according to George E. Whitwell, general sales manager of the company, indicated that 10 per cent of the residential lighting sockets were empty, and while this was not an exceptional condition the employee sales plan was adopted in an effort to remedy the situation because it was felt that the buying of lamps had not been made easy enough and because housewives had not been sold the idea of keeping a reserve supply of lamps on hand.

The work of the employees was stimulated by commissions on sales and the offering of additional cash prizes for those showing the best results. Sales promotional literature was furnished in connection with campaign circulars giving full information regarding the activities. Special order forms were prepared and furnished the solicitors showing various sizes of lamps and prices and employees were kept informed of progress by notations in the general sales manager's weekly bulletins and special bulletins were issued from time to time giving all details and status of the campaign.

Lamps were delivered by the company when desired by the patrons and charges were included on monthly bills for electric service. The special handy carton of assorted lamps was offered at a price of $2.47, containing two 100-watt, three 60-watt, two 40-watt and two 25-watt lamps. Although this was not the only way lamps could be purchased during the campaign, 3,383 of these special cartons were distributed. During this sale 15,683 100-watt lamps were distributed and 40 per cent of all lamps disposed of were of sizes 60-watt or larger.

Every effort was made, according to Mr. Whitwell, to assist competitive lamp dealers in increasing their lamp sales. They were kept informed of all activities in order that they might also "cash in" on the campaign. A series of advertisements was run in the newspapers, suggestions with reference to lamp buying were carried on customers' monthly bills and windows in various stores were suitably decorated. Local dealers were informed in advance of the dates on which these advertisements would appear and were also furnished with copies of reprints in advance in order that they might secure every possible help during the campaign.

# Profit vs. Volume in Pricing

Losses in business so general there must be a fundamental cause. Profit an obligation to progress. No justification for a company to operate without a profit if it fills a need

By W. L. CHURCHILL
*New York*

*A total productive capacity greatly in excess of the absorbing capacity of the market is pointed out by Mr. Churchill in this article as the basis of two companion evils: First, increased selling cost for selling effort is being expended to dispose of 100 per cent of the industry's capacity; second, price reductions are made in anticipation of a volume sale that is impossible of attainment. The net result is abnormal selling costs, subnormal selling prices and subnormal profits.*

FORTY per cent of all manufacturers are reporting deficits in their income tax returns on the average year after year; 70 per cent earns less than $5,000 net profit per year; only three firms out of five earn any profits whatever and only three out of ten earn more than $5,000 per year. The average net income of our entire manufacturing group is approximately $2,500,000,000 per year, or a little more than $20 per capita for our entire population. This is less than the amount that is being added to the investment in manufacturing enterprises year after year if the latest reports on this item from the Census Bureau are indicative of current trends. Manufacturing as an economic group does not earn enough to take care of its own expansion requirements created by our increasing population and increasing demand for manufactured products.

How accurately these figures reflect the conditions of the manufacturers engaged in the production of electrical equipment and goods would be difficult to determine. Assuming, however, that as a group it may rate well above the average of all of our manufacturing industries, it is quite obvious that profits are not commensurate with the service that is being rendered. Despite the outstanding and recognized success of prominent electrical manufacturing firms, the number of firms which are not regularly and consistently making a fair return to their stockholders and owners is altogether too large for the industry to assume any complacency over its own position in the structure of American industry generally.

### LOSSES CONTINUALLY SHIFT ABOUT

This is not a picture of a period of unusual depression. It is a picture that indicates just what occurred in 1927 and that prevailed during the prosperous year of 1926. Neither are the losses confined to small and irresponsible manufacturing firms. Deficits are reported by some of our largest and most prominent industrial enterprises that in times past have been very successful and profitable under the same management. Were it not for the fact that the losses shift about from industry to industry and firm to firm within industries, we would have a larger list of failures and receiverships than we now have.

A condition that is so general and that is not confined continuously to any product, group or class must have a fundamental cause or causes whose discovery will indicate the remedy or remedies. There is no justification for manufacturing enterprises, producing articles or products of service to society, operating without a profit. Quite the reverse is the case. Profit is an obligation, not merely to stockholders and owners but to progress. The manufacturing firm that makes no profit cannot out of its own resources conduct research, experimental and development work for improvement of its product or of its methods of production, or extend its markets. Being unable to do these things, it is unable to reduce costs or give greater values per dollar of sale, and as we cannot stand still, but must go either forward or backward, the firm that makes no profit sooner or later becomes a burden upon the community.

The opposite of this picture is that of a firm making not merely a profit but substantial profits. It is such firms that are responsible for developments and improvements in products that tend continually to lower their costs or give us greater values in the price of their products. It is the prosperous and profitable firms that improve, enlarge and add to their buildings, thus making business good for manufacturers of building materials and for the dealers, contractors, engineers, etc. It is the profitable firm that invests in new equipment, machinery and devices, that in turn employ designers and producers, all tending to increase our general business and progress. Even the cash dividends paid to stockholders become a means of stimulating all forms of business and professional services, improving our standards of living and our cultural levels.

When we recognize that to obtain products or services from worthy producers at prices that give them no profit we automatically restrict our own opportunities for business, then we will be just as insistent upon our suppliers obtaining a profit from our transactions as today we are eager to prevent it. When automobile manufacturers buy their steel at prices that mean a loss to the producers they automatically destroy a market for automobiles. This, in turn, correspondingly reduces the market for a large variety of electrical devices and equipment. This same reasoning can be followed through to suppliers of wire and other component materials, to the smelters and the mines. It takes but little imagination to see the beneficent effect upon all business derived from profits.

A few manufacturers are far-seeing enough to insist upon doing business only with suppliers who are to profit from the transaction. Others, although not taking quite so unusual a position, try to impress upon the people with whom they deal the importance of the transactions being fair to all parties; not for sentimental reasons but for purely selfish reasons. A large purchaser of public utility equipment has been known to criticise the manufacturers because the latter did not charge enough for their products. His reasoning was to the effect that the prices are so low that there are no profits with which to develop and improve the goods, so that they cost more than they would if liberal profits had been earned in the past and the product is not as advanced as it should be.

Manufacturers of electrical products have made tremendous progress in the short period during which the electrical industry as an industry has been in existence. In the earlier years it was fairly easy to obtain capital from other sources with which to start and develop electrical enterprises. It is getting to be more and more necessary that the industry find its own capital for its further development and progress from within its own sources. It must earn this capital in the form of profits or its progress will be seriously restricted. Electrical manufacturers are already making a beginning in the study of causes and the search for the remedy for existing conditions that are generally admitted to be unsatisfactory from the standpoint of profit as well as from the comparatively slow extension of markets.

### Inadequate Average Prices Chief Cause

The principal cause for both of these major conditions, low average of profits and slow development of additional markets, is that the average prices received by manufacturers of electrical (and other) products are inadequate to cover the costs of production and distribution and provide a surplus with which to pay stockholders cash dividends; to improve products so as to enlarge their demand, at the same time reducing their cost, and to enable lower prices still further to widen their demand. Simply stated, electrical manufacturers do not get enough for their goods. They do not get enough for their goods because they do not price them properly. They fail to realize that there are economic laws that must be observed in the pricing and merchandising of their products to insure their operating upon a continuously profitable basis and fulfilling their obligation to society as well as to the stockholders and owners.

As it will be impossible to deal with more than one of the several governing fundamental economic factors in this short article, I simply will touch upon one of the most important of these factors, that of the production volume upon which all costs and profits must be based for the establishment of sound selling prices for manufactured products. Most pricing of manufactured goods is done with the primary object of getting volume business. Electrical manufacturers, like all other manufacturers of established industries, have a total productive capacity greatly in excess of the absorbing capacity of the market for their products. This develops two companion evils. First, it increases selling costs, as selling effort is being expended to sell 100 per cent of the industry's capacity; second, it effects price reductions in anticipation of a volume sale that is impossible of attainment. The net result is that we have abnormal selling costs, subnormal selling prices and subnormal profits.

### Costs and Profits Based on Actual Production

To illustrate this feature, the case of the flour industry will be cited. The flour industry is chosen because of the simple nature of its product and the fact that government statistics are available in relation to proportion of production to capacity. For the year ended June 30, 1927, the flour mills of the United States (nearly 800) produced 55 per cent of their rated capacity, included in this being a considerable export production. An investigation discloses that efforts to sell 100 per cent capacity were adding to normal selling costs approximately 40 cents per barrel over and above that needed to dispose of what was produced. This investigation was necessarily limited, but if indicative of the industry as a whole would represent a needless expenditure of $50,000,000 a year that must be saddled onto the cost of the flour that is purchased and consumed. The profits of flour mills are approximately in line with those of general industry; the mills that succeed in obtaining a volume in excess of the average make some money, but the industry as a whole is no better than the average of all of our American industries. Our per capita consumption of flour is about one barrel per year. No amount of sales effort, advertising campaigns or other marketing activities can appreciably increase the consumption of flour in the United States; it is limited by the size of the great American stomach and can be increased only by displacing other products. What is true of flour is true of electrical products, except that the limitations of the American market are restricted to the size of the American dollar.

The electrical manufacturing industries, or different subdivisions thereof, may be disposing of 60, up to, in some cases, 75 per cent of their aggregate capacity, but you may rest assured they are not disposing of 100 per cent or anywhere near that on the average the year round. Figures recently compiled of representative groups of manufacturers, even in the busy period of 1927, range all the way from 40 per cent to 84 per cent. The automobile industry in 1927 operated at about 62 per cent capacity and it is increasing its capacity. A recent statement from the United States Steel Corporation was to the effect that over a period of six years it had operated at 66.6 per cent of capacity. These figures are merely cited to show that manufacturing firms which find that they have considerable idle or semi-idle capacity should first determine the relationship of their production to that of the average of the industry before spending excessive amounts merely to switch trade from some other producers to their plants. They must know upon what proportion of capacity they must build their costs and determine their profits for the purpose of establishing the selling prices before their cost systems can be used as the basis for guiding them to continuously assured profits and the perpetuation of their businesses.

Electrical manufacturers are catering to an expanding business, but productive capacity expands at an equal or greater rate, so that in effect the industry as a whole is selling to a saturated market. The limitations of this market are the limitations of the money available to invest in electrical devices, objects and equipment. Increase the dollars available for expenditure by the American public for its luxuries, conveniences and necessities and the electrical industry will get a major portion of this increase, as most of the things that we desire today either are directly connected with electrical manufacture or are produced with the use of electrical equipment. The logical means for increasing the money available to the American public is to increase the profits to the large body of American stockholders and owners. To accomplish this it is necessary that all transactions of manufacturing enterprises be conducted with the primary object of profit. When products are priced so low that it is necessary to sell an abnormal volume to insure normal profits these can be secured only by reducing profits and even creating losses for competitors whose trade is diverted away from them. This brings about retaliations; prices are met and still further reduced and normal profits cannot be sustained.

### Principle of Pricing an Individual Problem

Fortunately it is not necessary for an individual firm to wait for its competitors to accept and apply the principle of pricing its products upon a basis that will earn it a normal profit when it produces its normal quota of the offering business in order that the adoption of this principle may enable it to operate profitably. Intelligent merchandising will enable proper prices to be obtained and a sufficient quantity of goods to be sold to insure profits. If the merchandising is especially well conducted more than the normal quota of sales will be secured, but at prices that will insure greater than normal profits. On the other hand, sales may fall substantially below the normal quota of business before profits will drop to present average levels if they are subnormal.

It is useless for us to quarrel with the fact that surplus capacity exists. It does exist and in all lines. As fast as we develop business fully to absorb our operating capacity we immediately increase that capacity. Most industries find that at times they are required to utilize all of their capacity, even though it may be but for short periods. Other manufacturers are constantly seeking additional lines, often going entirely outside of their established fields to find articles to produce that will take up the slack of their idle equipment and more fully utilize their organizations. This, in turn, increases the productive capacities of the lines adopted, so that there is a tendency toward the equalization of the utilized capacities of all of our industries. There is a continual effort of adjustment of supply to demand. Our capacity to supply is greatly in excess of demand at present. It is not, however, in excess of the needs and desires of the buying public, but merely in excess of their ability to satisfy them. When manufacturing enterprises earn the profits that they should there will be a large addition to the funds now available to increase the demand.

We have seen the effect of increased wages upon business. Similar effects will follow the elevation of profits to their proper levels. There is nothing reprehensible about profits in themselves. Profits must be earned if we are to continue to progress. They are as well an obligation to stockholders and owners. This thought has been aptly expressed by the Illinois Manufacturers' Cost Association in its report on "Financial Burden in Cost." The concluding paragraph of this report states:

> From a moral, financial and sound business standpoint stockholders are just as much entitled to reasonable returns in the shape of dividends as bondholders are entitled to their returns in the shape of interest. The management of every business and industrial organization assumes a serious responsibility when it accepts stockholders' money. It should expect to meet this responsibility at all times.

To insure this result, manufacturers must adjust their prices so that these profits will be secured when they sell their quota of the offering business. There is no choice in this matter if the primary object is consistent and regular profits that will put manufacturing upon a basis that will make it a sound investment instead of a precarious speculation.

Pricing for profit instead of pricing for volume does not necessarily imply a loss of business. Intelligent merchandising will overcome the tendency in this direction and secure the profits through which cost reductions may be effected and prices lowered to the further benefit of all business. It has been estimated that American manufacturers ought to be earning at least $5,000,000,000 more profits per year than they now obtain. The electrical industry can assist manufacturers generally toward this goal by pricing for profit instead of pricing for volume.

## Invites Motorists to Plants and Emphasizes Power Resources

Travel on MAINE'S MILLION DOLLAR HIGHWAY
ROUTES 26-100
Lewiston-Auburn
The INDUSTRIAL CENTRE of NORTHERN NEW ENGLAND
Visit Gulf Island Dam - Abundant, Cheap, Hydro-Electric Power - New Industries

TOURISTS in the Androscoggin Valley of Maine are invited to visit the new Gulf Island hydro-electric plant of the Central Maine Power Company through the co-operation of the Lewiston-Auburn Chamber of Commerce and the utility, as indicated by the above billboard, which occupies a prominent place beside a new motor highway traversing this district. The attraction of industries by cheap power is effectively featured by this business organization.

## Latest Data on Farm Electrification

A VALUABLE contribution to the available information on farm electrification has just been published by the Committee on the Relation of Electricity to Agriculture in a 136-page booklet, "Electricity on the Farm and in Rural Communities." The booklet, which is issued as C.R.E.A. Bulletin, Vol. 4, No. 1, sets forth material which represents a summary of the best information at the command of the committee regarding rural uses for electricity.

In addition, it contains a review of the organization and activities of the various state and national associatons, agricultural colleges, experimental stations and the power companies working through the Committee on the Relation of Electricity to Agriculture to solve the problem of getting electric light and power service to the farms of the United States.

Among the data presented is an estimate of the number of farms in the country having electric service based on the results of a survey conducted by the rural electric service committee of the National Electric Light Association showing that 227,442 farms in 27 states had service from high lines on Jan. 1, 1927. This was an increase of 86 per cent for the same 27 states over Jan. 1, 1924. On this basis it is estimated that between 300,000 and 350,000 farms in the United States were receiving electric servce from distribution lines on Jan. 1, 1927.

It is significant with reference to the future development of rural electric service that 100 electric light and power companies report one or more men giving especial attention to this subject. Of this number 53 companies report the organization of rural electric service departments or divisions.

Other information set forth in the bulletin discusses different phases of the rural service problem, and the major portion is devoted to specific data on energy consumption of domestic and power applications of electricity on the farm. This information is given in an extensive description of the various applications and supplemented with some 80 tables and 208 illustrations.

## Uses 30-Amp., Single-Pole Blocking Switches

By C. E. Schnell

*Electrical Designing Engineer San Joaquin Light & Power Corporation, Fresno, Calif.*

Even with increasing efforts directed toward better and more positive relay protection and with constant refinements in oil circuit breaker design and application to give greater continuity of service, still there are many things which enter into the complete scheme of operation of equipment which may defeat the purpose, such, for instance, as the blocking switch ordinarily inserted in the oil switch trip circuit to render the breaker nonautomatic or when it is desired to inspect or work on relays.

Experience of the San Joaquin Light & Power Corporation has been with the use of a somewhat varied line of switches for this service. The single-pole indicating snap switch, the single-pole tumbler switch with indicating handle and the single-pole knife switch all have been used. The two first mentioned have caused trouble due to incomplete and uncertain contact as well as flimsy construction, and while the tumbler switch gives the better appearance it has been the worst offender in this regard. While perhaps not so pleasing in appearance on the face of a switchboard, but because of more rugged construction, it has been decided to use for this service 30-amp., 125-volt, single-pole, single-throw knife switches mounted on the front of the board, but with studs for rear of the board connection. These are located near the relays whose tripping circuit they control and not only make a positive contact when closed but give a very desirable visual indication of their position at all times.

Blocking switches are operated only on direct instructions from the system load dispatcher, and it is the operator's duty carefully to check his board for proper position of these switches. During system disturbances, when an important line may be out of service, it is possible by opening the blocking switches on other lines to load them in excess of their normal relay settings until the period of such emergency operation is over. This does not disturb the relay setting and the blocking switch is closed on return to normal conditions, thus again making the automatic protective features effective.

## Refractor-Plate Lighting Gives Even Window Illumination

The department store of the C. T. Sherer Company, Worcester, Mass., is reported to be the first in the country to be equipped with prismatic refractor-plate window lighting. The installation is wired and equipped for a total capacity of 500 watts per foot overhead, the use of 150 watts per foot for the foot lighting, and numerous other outlets for floods, displays, etc. The present load of the windows is 350 watts per foot, including foot lighting. Seventy-eight plates and reflectors are used in three front windows; 88 circuits are provided for these, with 50 additional circuits for five side windows. Of the former, about 60 are used for overhead and foot lighting.

The illumination equipment consists of a row of light-directing Holophane plates, each about 1 ft. square and mounted separately or in groups in walnut frames. Each frame is fitted with hinges and latches to permit easy maintenance, lamp renewals and the insertion of color equipment. Plates and reflectors for this installation are mounted at an angle, the inner edge of the plates being at the ceiling line with the edge nearest the glass dropped 15 deg. below the horizontal. In addition, the light distribution is controlled by the filament distance from the plate surface and by the offset position of the reflector to the axis of the plate. Reflectors are mounted on Curtisstrip. In this type of construction the wireway rests on blocks cut at the desired angle. The reflectors can be moved either horizontally or vertically to obtain the desired lamp position.

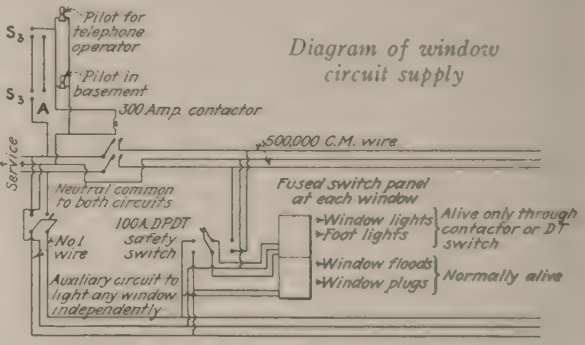

Diagram of window circuit supply
$S_3$
$S_3$
A
Pilot for telephone operator
Pilot in basement
300 Amp. contactor
500,000 C.M. wire
Service
Neutral common to both circuits
Fused switch panel at each window
100 A. DPDT safety switch
No. 1 wire
Auxiliary circuit to light any window independently
Window lights
Foot lights
Alive only through contactor or DT switch
Window floods
Window plugs
Normally alive

These windows are wired for two-point remote control at switches $S_3$, or control by clock or other switch at $A$. An auxiliary supply circuit independent of the contactor control is provided with a double-throw safety switch, enabling the major window displays to be lighted by either of the branch circuits shown.

An important feature is the use of spill light. No housing is located over the reflectors, and this light therefore is allowed to illuminate the store ceiling and, still more important, a light-toned transom curtain. Viewed from outside, there is an attractive effect of size and height along the entire store front which would be absent if everything above the window proper were left in blackness.

The foot lighting is unique in the use of 6-in. prismatic plates in place of the ordinary clear or diffusing glass. This results in improved distribution, doing away with the flux in so many other cases thrown into the eyes of passers-by. Lamps are located back of every other plate, or on 12-in. centers. As seen in the corner window, all plates appear to have about the same brightness, though differences can be noted when viewing them from inside or at comparatively wide angles. For the foot lighting 100-watt lamps are used. The foot lighting approximately doubles the background intensities at the desired heights.

At present the overhead lighting is by 200- and 300-watt lamps installed alternately along the window frontage portion of the ceiling.

For the current supply to the windows a feeder circuit of 500,000 circ.mils is installed, equipped with a remote-operated contactor. Control buttons and pilots are provided at two different points for turning all the windows on or off. The contactor method of control allows the use of any auxiliary device, such as a low amperage time clock, if desired. An auxiliary circuit also feeds double-throw switches at the switch cabinet for each window, which enable any window to be lighted independently for special occasions or during decorating and trimming work.

## *Purchasing Agent Not Concerned With Price Cutting*

*To the Editor of* ELECTRICAL WORLD:

Referring to your recent article entitled "Who Pays the Cost of Price Cutting?" I would like to speak a word for the purchasing agent. The old law of supply and demand regulates the price of the commodity, and we are only concerned with getting values proportionate to the money we pay at the time of purchase, predicated on the price of raw material at that time. Price is important with us, but we want the best material we can buy, at the best price the manufacturer can make us, without his losing money, as we know no manufacturer can thrive without making a profit.

Speaking about the methods of buying, all deceit, trickery and pitting of salesmen against one another, as mentioned in your article, should be stopped.

On all large purchases, where bids are asked for, on electrical or any other material, where specifications, blueprints, etc., are furnished, and all bidders are bidding alike, the lowest bidder should be awarded the contract. If it is stated that all bids are to be in at a specified time, then, after all bids are in, no bidder should be allowed or asked to revise his price. This is the only way to get honest competition, as the bidder knows he is getting a square deal and, if his price is the lowest, will be awarded the contract. If the purchasing agent feels that the prices are out of line and too high, all bids should be rejected and new bids asked for.

The purchasing agent is not concerned with price cutting; we want the best price, predicated on the price of raw material, and want value received for the companies we represent.

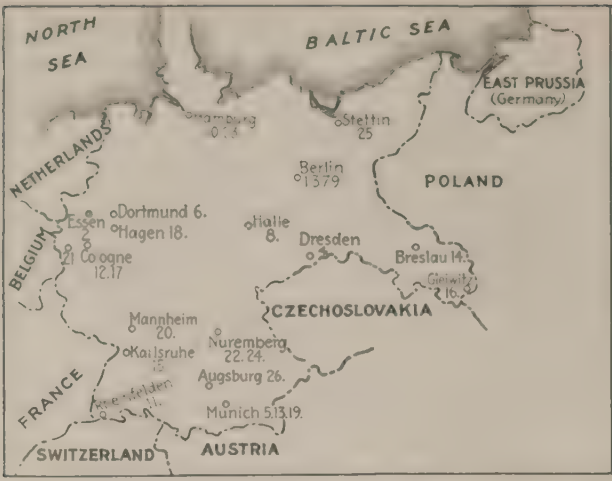
JOHN R. MCGIVNEY,
Purchasing Agent.
New Orleans Public Service, Inc.

## *How Electrical Development Is Proceeding in Germany*

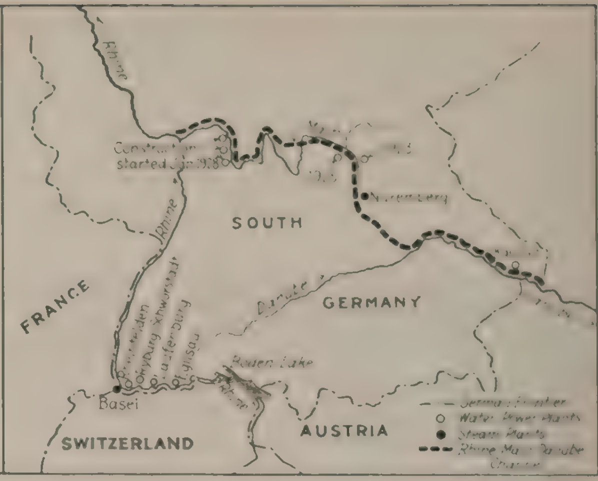
*To the Editor of* ELECTRICAL WORLD:

Official statistics published in the last half of 1927 show that at the close of the preceding year there were in Germany 26 generating stations, devoted mainly to the public supply of electric light and power, each of which sold more than 100,000,000 kw.-hr. in 1926. Two of these stations disposed of an output exceeding 1,000,000,000 kw.-hr. The table shows the capacity and the sales of these plants. With these figures as a background, the latest undertakings in Germany in connection with the supply of electricity stand out in their proper significance.

The undertaking of the Rhine-Main-Danube Company, founded in 1922 to build a waterway connecting the River Rhine—rising in the Alps and running through west Germany—with the Danube, which flows through the southern part of Germany before crossing Austria, Hungary and the Balkan countries on its way to the Black Sea, is on its way to successful completion. The project involves a wide channel navigable by boats of 1,500 tons, but its importance from the electrical point of view lies in the water-power sites developed concurrently with the improvement in navigation. These will, when completed, deliver to 35 power stations nearly



*Cities in which the largest German light and power companies have headquarters*



*Rhine-Main-Danube Channel and hydro-electric plants on the upper Rhine*

(The numbers refer to the table)

1,500,000,000 kw.-hr. a year, the average aggregate load of the stations being estimated at 250,000 hp.

The waterway is to run from the Rhine to the Main, crossing the Jura Mountains and descending again to the Danube. The power plants are built on sluices supplied from the main canals. The first plant was opened in 1923 with 4,350 hp., the second in 1925 with 4,800 hp. The largest plant yet built, not far from the point where the Danube leaves German territory, was begun in 1922 and went into service in the last months of 1927. It is rated at 75,000 hp. and generates nearly 275,000,000 kw.-hr. annually. Energy from it is distributed by the Betriebsgemeinschaft Kachlet-Franken, which, besides this enterprise, leases at Nuremberg, Bavaria, the 80,000-hp. plant of the Grosskraftwerk Franken.

Construction of the Rhine-Danube waterway has been made possible only by its power-generating features, the income of the power stations being charged with 90 per cent of the cost of the scheme. As utilization of the energy grew slowly in extent, construction of hydro stations was suspended for a few years, but in January last three additional ones were begun under contract with the Bavarian State, and everything now indicates that the project will be carried out in its entirety.

On the upper reaches of the Rhine also construction of a large hydro-electric station, to be known as the Ryburg-Schwörstadt, has recently begun. The Upper Rhine has a fall of 500 ft. between Boden Lake and the town of Basle, 104 miles distant. A channel for large ships is to be built through the rapids. As the Rhine at this point forms the boundary between Germany and Switzerland, these two nations will share in developing the sixteen sites selected. The existing power stations on this part of the Rhine are rated as follows: Kraftübertragungswerke Rheinfelden (German), 48,400 hp.; Laufenburg (Swiss), 69,000 hp.; Eglisau (Swiss), 42,000 hp. The new station, a few miles above Rheinfelden, will have four Kaplan turbines, with a total capacity of between 40,000 hp. and 120,000 hp., according to the flow. A possible development of 500,000 hp. is indicated. The output will average 650,000,000 kw.-hr. a year. Four shareholders have an equal interest in the undertaking—the Swiss government, the German state of Baden, the Kraftübertragungswerke and the Swiss company "Motor-Columbus," which owns the Laufenburg development. The plant will cost 60,000,000 Swiss francs (about $11,500,000), and energy will be generated, it is estimated, at a primary cost of about 0.3 cent a kilowatt-hour. GERHARD DEHNE.

Berlin, Germany.

# Digest of Electrical Literature

## *Transmission, Substations and Distribution*

*Kelvin's Law for High-Voltage Transmission Lines.*—R. Roberts.—An exposition of the fundamental characteristics of the economic law for electrical power transmission developed many years ago by Lord Kelvin and adapted to the requirements of modern practice, with particular reference to conditions in Australia. It is stated by the author that while the law remains fundamentally correct in principle it is, when applied to modern high-voltage transmission lines, not the simple relationship it was once thought to be. In this discussion the formulas and load charts necessary for the development of the idea and a critical discussion of the values involved are offered. As a result of this investigation it is concluded that it is in general desirable to have synchronous condensers distributed over large transmission systems, but placing the centers of gravity at the loads; induction regulators should be used for particular feeders emanating from generating or substations, and that as there is an economic section of transmission line conductor, it is apparently preferable to use this economic section and to control the line pressure by devices located where necessary, although large copper sections for regulation purposes only are economically unsound.—*Electrical Times (Australia)*, Jan. 27, 1928.

*Problems in Connection with Three-Phase Star Loads.*—Alexander Russell.—The discrepancy between the value of the power factor of a balanced three-phase load obtained by the two-wattmeter and the three-wattmeter methods is mentioned by the author, as is the deviation in the ratio of the mesh voltage from the star voltage to earth from the theoretical value of the square root of 3. The author investigates the reasons for these variations and with the help of solid geometry develops a pictorial method of considering the problem. It is proved that the square root of 3 is the maximum value of the ratio of the mesh voltage to the potential difference between a terminal and earth. It is also indicated that a star inductive load only has an equivalent mesh load when the time constants of the arms of the star load are all equal.—*Journal of the Institution of Electrical Engineers (England)*, February, 1928.

## *Units, Measurements and Instruments*

*Determination of the Moment of Inertia of an Electrical Rotor.*—T. F. Wall.—Several methods of measuring the moment of inertia of rotating parts by means of the principle of oscillations are offered by the author and numerical values obtained by these measurements for specific machines are offered and compared. It is stated that the calculation of the moment of inertia of a composite structure like the rotor of an electrical machine is a very laborious process and cannot be expected to give accurate results without a great deal of arithmetical work. The methods considered include: The rotor removed from its bearings and arranged with its shaft supported on horizontal knife edges; the rotor suspended by means of ropes and wires and oscillated under gravity control; the rotor suspended by a single steel wire and allowed to oscillate torsionally about the axis of the shaft; the rotor caused to oscillate in small bearings about its shaft axis. The values obtained by these methods are useful in securing actual quantities for the measurement of the losses of the machine. It is stated that the performance of alternators in parallel is largely dependent on the magnitude of the moment of inertia of the rotating members of the respective machines.—*Engineering (England)*, Feb. 24, 1928.

*Extensometer for the Determination of Young's Modulus for Concrete.*—V. C. Davies.—The author has devised an extensometer particularly adaptable to the measurement of concrete test specimens. In the design particular efforts were made to secure an instrument which might be placed on the specimen while the latter is in position in the testing machine and which would be able to take specimens up to 4½ in. square. Previous experience on delicate extensometers has shown the necessity of securing a device which can be calibrated when fixed in position for test. The method of calibration employed is identical with that used in the well-known Ewing extensometer. The actual measuring device is arranged to measure the relative movement of a hardened steel screw fixed in the bottom frame and the flattened face of a cylindrical rod fixed in the top frame. The end of the calibrated micrometer is made hemispherical and this makes contact with the hardened steel cone fixed in the top frame. A bell-crank lever is pivoted to the framework so that the motion of the hand is magnified through a contact point by about 5 to 1. The end is provided with a jewel end-stone, making contact with the hardened steel point projecting from the frame of a swinging mirror. The movement of the bell crank is resisted by a long light cantilever spring, while contact between the point on the mirror frame and the end of the frame is maintained by means of a hairspring placed on the pivot arbor of the mirror. Both bell-crank lever and mirror frame are carried on cone pivots fitting into conical holes in the ends of small hardened steel screws.—*Engineering (England)*, Feb. 3, 1928.

## *Heat Applications and Material Handling*

*Industrial Electric Heating.*—The results obtained with specific installations of industrial electric heating in several British manufacturing plants are covered by this article. Operating costs developed as a result of several investigations indicated that the cost of maintaining an electrical industrial heating device was no higher than that for any other apparatus and that the same statements might be applied to operating costs giving in many cases a total cost much lower than that when other forms of heat treatment are used.—*Electrician (England)*, Feb. 3, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*Modern Research on the Structures of Metals.*—Wheeler P. Davey.—Research and development work with X-rays has been the special consideration of the author in this report of the activities of industrial research laboratories. The problems have been divided into several classifications, including, getting the factory out of manufacturing difficulties; development of new products and processes, and search for new scientific principles which may be applied to industry. It is stated that it is in the discovery of new facts or hitherto unknown ones upon which the future factory processes may be developed that the greatest usefulness of X-ray investigations is found. Practically all work of this sort depends upon the measurement of inter-atomic distances. These distances are so small that they cannot be measured directly. By the use of X-rays of known frequency in conjunction with the application of an X-ray defraction apparatus as a micrometer, these extremely small distances may be evaluated. Mention is also made of the method by which study may be undertaken of the mechanisms of melting which serve to correlate the melting point with the total expansion of the metal from absolute zero to the melting point. It is said to have been possible to prepare wire of certain alloys in a state of extreme purity by never permitting the metals to become melted even when making the alloy. Reasons for variations in physical properties are given.—*Journal of the Franklin Institute*, February, 1928.

*The Effect of Impurities on the Corrosion of Metals.*—Colin J. Smithells.—The prevention of corrosion is one of the most important problems confronting engineers and metallurgists at the present time and the enormous saving which results from each advance in this direction constitutes an important step in present-day engineering practice. Among the factors which influence corrosion the composition of the material is one of the most important. In this article the effect of impurities in metals is discussed in relation to the modern electrochemical theory. It is stated that the main factors which determine the influence of impurities on corrosion are electro-potentials of the metal and the impurity, the hydrogen ion concentration, the over-potential value of the impurity and the character of the corrosion product. Specific considerations for the more common metals and for the product formed by their destructive corrosion are offered in connection with the discussion. In conclusion, the author states that while the electrochemical theory leads to an expectation that corrosion resistance will be closely related to the constitution and structure of a material, the examples given indicate that it may also be applied to those small variations in composition which naturally occur in manufacture. Comparatively small changes in composition or the introduction of impurities to the extent of less than one part in ten thousand may materially modify the ability of an alloy to withstand corrosion in service.—*World Power*, February, 1928.

## *Illumination*

*Lighting in Industry.* — DUGALD C. JACKSON.—The problems involved in industrial lighting have been reduced largely to a research basis in this discussion. The subject is stated to involve three branches of science—physics of light, psychology, and physiology. The research was divided into a study and analysis of the scientific and industrial literature to determine previous accomplishments and a sound basis on which to start on a new investigation; experimental work by psychologists to supply certain information regarding sensitivity, discrimination, acuity, and fatigue that seem to be important in such an investigation; experimental work of a laboratory nature or under controls corresponding to those of a laboratory for the purpose of securing an understanding of the relation of scientific investigation of the conditions under which the conclusions may be applied when they are carried out in industry, and co-ordinated research in the study of factory workers, measurements of factory production, under different conditions of illumination, surveys of eye strain and general fatigue, and the adaptation of conclusions and inferences secured in the other branches of the investigation to application in the procedure, observation and conclusions of this branch, along with suitable verification of the soundness of the conclusions regarding "workers' efficiency." This discussion, the author of which is chairman of the Committee on the Relation of Quality and Quantity of Illumination to Efficiency in Industry, has resulted in a number of interesting recommendations and determinations. — *Journal of the Franklin Institute*, March, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*The Measurement of Acoustic Impendance and the Absorption Coefficient of Porous Materials.* — E. C. WENTE and E. H. BEDELL.—Various ways of determining the acoustic impedance and the absorption coefficient of porous materials from measurements on the standing waves in tubes are discussed. In all cases the material under investigation is placed at one end of the tube and the sound is introduced at the other end. Values of the coefficient of absorption of a number of commonly used damping materials as obtained by one of the methods are given. Several types of built-up structures are shown to have a greater absorption coefficient for low frequency sound waves than is conveniently obtainable by a single layer of material.—*Bell System Technical Journal*, January, 1928.

*Methods, Formulas and Tables for the Calculation of Antenna Capacity.*—FREDERICK W. GROVER.—The calculation of the capacity of an antenna has been developed upon the assumption of a certain charge upon the antenna and from which the resulting potential may be calculated. As the law of the distribution of the charge is not known difficulties are encountered in this method. The assumption has been made that sufficient accuracy is attained if at first a uniform distribution of charge is supposed to exist and the potential calculated at various points of the antenna, the average of these potentials being taken as the final equilibrium potential, but as the discrepancies between the values obtained by this method and the published values for the same antennas by the inductance method differ a factor of uncertainty is involved. The author demonstrates that if appropriate inductance formulas are employed the two methods will agree. Formulas are given for the common types of single and multiple wire antennas in a form convenient for numerical computation, together with tables of constants which will be found useful in such calculations. In addition tables of capacities of both horizontal and vertical single-wire antennas and horizontal two-wire antennas have been included which should render all calculation unnecessary in many important practical cases. —*No. 568 Scientific Papers of the Bureau of Standards.*

*The Attenuation of Wireless Waves Over Land.*—R. H. BARFIELD.—A description of a series of experiments undertaken to determine the attenuation of wireless waves over land. The intensity of the signals from the London broadcasting station 2 LO was measured along a number of radial lines in seven different directions up to a maximum distance of 100 miles. As a result of these measurements curves were prepared of the over-all attenuation, and derived curves showing only the surface absorption effect were produced. The experimental results were then compared with those obtained in accordance with the theory of Sommerfeld. The results indicate that the effects are not the same in all directions, the difference being quite important and considerably greater than that to be expected from previously determined values of the earth's conductivity. The conclusion of the author was that the greater part of the discrepancy between Sommerfeld's theory and experiment could be ascribed to the effect of trees, and also that the same agency offered a satisfactory explanation of the difference of attenuation observed in different directions—the greatest attenuation corresponding to the most-wooded regions, and vice versa.—*Journal of the Institution of Electrical Engineers (England)*, February, 1928.

## *Miscellaneous*

*Light Metals and Alloys—Aluminum, Magnesium.*—The physical and mechanical properties of aluminum and magnesium and their light alloys and the variation in properties caused by changing the composition of the alloy, by the presence of impurities, by mechanical working, by changes in conditions of manufacturing operations and by heat treatment, are given. The selection of the data available has been made and the data have been checked by representatives of the light-alloy industries in order to present reliable information. Equilibrium diagrams for the important alloy systems are presented, and the metallography, corrosion resistance and methods of protection against corrosion, the theory of heat treatment and the application of the alloys to industry are likewise discussed.—*No. 346, Publications of the Bureau of Standards.*

*An Electric Suction Dredge.*—An electrically operated suction dredge receiving power on board the vessel at a potential of 11,000 volts has been installed in a government development scheme in New Zealand. Power is taken from an 11,000-volt, three-phase transmission line at such points as may be nearest the section of the river to be dredged. An overhead line is run from there to the river bank and is carried in each direction for 1½ or 2 miles. A cable may also be laid across the river and other lines have been erected for same distance on the opposite side. The tap line is protected on the pole nearest the transmission line by an air-break switch, an oil switch with over-load trips and similar equipment. Air-break switches are erected at intervals on the river bank to enable the dredge engineers to isolate part of the line they are working on without the necessity of going to the extreme end of the tap line to do so. While the dredge is operating on one section the lines erected in a previous section are taken down and re-erected as desired. From the high-potential compartment a three-core cable is taken to a 300-kva., 11,400-volt, oil-cooled transformer and from there to a low potential compartment with distribution to the main pump motor control panel. — *Electrical Review (England)*, Feb. 24, 1928.

# News of the Industry

## Johnson Submits Boulder Dam Report

### California Senator Argues that the Bill Is Well Considered and Sound—House Committee Preparing New Measure on Muscle Shoals—Trade Commission Questionnaire

SENATOR JOHNSON of California on March 21 submitted to the Senate the majority report on the Boulder Dam bill. The report covers 31 printed pages. The amendments are discussed and the general project is outlined. Reasons are advanced to show why the project should be financially attractive to the government. Another section attempts to prove that the project has been fully investigated and that the federal government is the proper agency to undertake the development. A chapter is devoted to the Colorado River compact, and arguments are advanced in an effort to show the urgent need for flood control. Still another part of the report deals with the feasibility of the all-American canal and tries to show that there is not sufficient water for all. A chapter is devoted to power and an effort made to demonstrate that the project is financially sound. In conclusion the report says:

> The people of the Southwest are not asking of the government this great public improvement as a gift. All they ask is that the government lend its good offices to make this development possible. Established communities and responsible agencies will bind themselves to return to the government all moneys expended. The varied interests concerned with the development make a centralized agency necessary. The government is the logical agency. The beneficiaries assume all the financial obligations. Nor is this quite all. After the development is paid for the government still will retain ownership and control of the dam for such use as the Congress may deem wise and just. It is a great constructive improvement, not experimental, sound financially, well considered, shaped in the public interest, one the consummation of which will be a source alike of national pride and advantage.

Representative Douglas of Arizona has submitted a minority report from the House committee covering 45 printed pages. In it he says that he is opposed to the measure because of its unsound economic nature and not because he represents Arizona. He emphasizes particularly the contention that the project is not one for flood control, irrigation, domestic water or navigation, but does look to the development of the largest power project ever owned and operated by a government.

#### ANOTHER MUSCLE SHOALS BILL

After voting down the Norris Muscle Shoals bill (transmitted from the Senate), the Madden bill and the Morin bill, the House committee on military affairs has plunged into an effort to bring out a bill of its own. This bill is expected to set up a hundred-million-dollar government corporation to operate the property, make fertilizer and sell the surplus power. It is a radical departure from the Senate's plan and is not likely to meet approval there.

The House committee was not satisfied with the Norris bill because of its infringement on the rights of the states in the matter of control of rates and because the members did not regard the plan for fertilizer as a practical one. The Madden bill was even less acceptable. Some members of the committee feel that it is a gesture toward fertilizer production with the real intent of obtaining the power. The fertilizer guarantee was not satisfactory. The fact that the bidder for the property was not willing to turn it back if the fertilizer production should not succeed is cited as evidence strengthening the committee's impression. The refusal of the bidder to increase the offer when it was established that the Cove Creek dam and dam No. 3 would cost more than had been estimated also had influence.

The House committee regarded the Norris bill as a hodgepodge measure, interlocking the responsibilities of two executive departments in an impracticable fashion and complicating rate regulation. There was objection to additional installation on the ground that that depreciation would more than offset the limited use which could be made of the additional equipment. The fact that this machinery would use only secondary power would render it of small value unless the plant were a part of a large system.

Another suggestion which has been put forward is that the President be empowered to lease the plant. Should he fail to receive offers satisfactory to him, he is to be empowered to operate the plant until such time as a satisfactory offer may be forthcoming.

#### TRADE COMMISSION QUESTIONNAIRE

An eleven-page questionnaire has been sent to all electric and gas public utility companies by the Federal Trade Commission in connection with its inquiry into the conduct of those activities. The principal information requested follows: State of incorporation; date of incorporation; production; purchases and sales; distribution within state; distribution in other states; production within state; production in other states; companies from which purchases were made since Jan. 1, 1927; location and capacity of plant; names of companies with which interconnected; states in which transmission and pipe lines extend; gross earnings for 1927; net earnings from operations; number of shares, par value and book value, common and preferred stocks as of Dec. 31, 1927; amount of bonds and other long-time obligations; surplus; surplus reserves; persons or companies owning 1 per cent or more of voting stocks; ownership of stock in other companies; names of directors and chief officers; names of companies performing management, engineering, financing, construction, purchasing or other services.

A favorable report on the bill authorizing the Federal Power Commission to employ its own personnel has been made to the House by the committee on interstate and foreign commerce.

## Senators Find Fresh Fault with Utility Companies

Charges against the public utility industries continue to be made by United States senators. On Wednesday Senator Johnson of California read a photostatic copy of a letter which he said had been broadcast by Milton W. Harrison, president of the National Association of Owners of Railway and Public Securities, to holders of such securities, urging them to unite for protection "against unsound public discussion and unwise legislation" and to contribute $1 apiece to that end. The California Senator declared that if every stenographer, clerk and employee of corporations who had purchased a share of stock in them were to make a contribution, the collection would rival any fund ever collected.

At the same time Senator Walsh of Montana charged that public utility associations were "subsidizing lecturers and professors in colleges to instill in the minds of the youth of the land their peculiar views of public questions." Senator Norris of Nebraska wants a Federal Trade Commission investigation into newspaper purchases said to have been made or to be pending by Ira C. Copley, a former member of the House of Representatives and well-known utility man in the Middle West.

## Radio Bill Passes House

The conference report on the bill extending the life of the Federal Radio Commission for another year and embodying the new plan of distributing wave lengths and power was adopted by the House of Representatives on Wednesday, almost without opposition. Indications are said to be that the report will be accepted by the Senate and approved by the President.

## Engineering Section, N.E.L.A., Adopts Objectives

At the meeting of the executive committee of the Engineering National Section of the National Electric Light Association held at Louisville this week definite objectives were approved for the engineering committees to work toward. These objectives, as stated by Chairman E. C. Stone, are: More system capacity per dollar of investment, more kilowatt-hours per kilowatt of system capacity, a definite advance planning of system development and co-ordination of adjacent systems, comprehensive research in fundamental engineering problems of the industry co-ordinated through the committees, better conduct and wider distribution of serial reports, study of (and when desirable reports on) national engineering issues affecting the industry, constructive co-operation in the national movement for standardization, and greater engineering service to the industry through closer co-operation with the other national sections of the N.E.L.A. These objectives were approved with enthusiasm by the section members.

The various committees of the section met to discuss current work and to plan future work. The desire to realize more from investment dollars was evident in all the meetings, and much work was discussed or planned to bring about this result. Layouts for power stations, transmission systems, substations and distribution systems were analyzed to ascertain the best way to get acceptable service with a maximum simplicity in layout and a minimum investment. The use of automatic devices to reduce labor charges and improve performance was measured in terms of relative capital and operating costs in power stations. The prime movers committee discussed recent designs in terms of operating performance in an attempt to reach conclusions which would lead to maximum investment efficiency in the generation of energy. The overhead systems committee dealt largely with standards for wires, cables and construction whereby investment savings might be realized and better service rendered. Much was done to co-ordinate test work by utilities on such apparatus as oil breakers, lightning arresters and cables.

Technical discussions on metering, cable research, bin and unit pulverized-fuel systems, system frequency and load control and oil breakers took place in committee, and serial reports were presented and discussed which dealt with important engineering subjects. Accident prevention and inductive co-ordination committee activity was along constructive lines. General discussion showed a consensus of opinion against the proposal to merge the Safety Code and the Electrical Code.

Inspection trips were made to the hydro and steam stations in the vicinity and to Mammoth Cave.

# Collapse of St. Francis Dam Unexplained

### State, City and County Engineers Have Differing Opinions—Southern California Edison Gains Credit—City's Resumption Plans—Mead Will Head Investigators

ALTHOUGH agreed in discounting any theory that the St. Francis Dam disaster resulted from dynamiting or other sabotage, widely diverging opinions as to what caused the structure in San Francisquito Canyon to collapse and spread death and destruction throughout the Santa Clara River Valley have been expressed by engineers on the ground.

Edward Hyatt, Jr., State Engineer, blames foundation weakness in the abutments of the dam, refusing to express an opinion on whether the collapse was due to engineering mistakes or to causes over which man has no control.

William Mulhollan, chief engineer of the Los Angeles Bureau of Water and Power, under whose supervision the dam was built as a unit of the city's water system, declared his belief that a series of landslides above the dam caused the collapse. Other Water and Power Bureau engineers reported finding evidences of three slides.

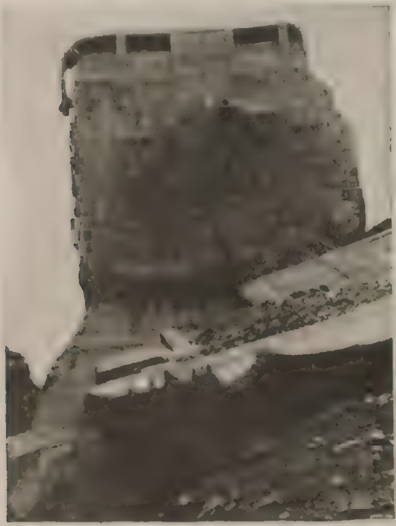
Charles Petit, county engineer of Ventura County, sharply criticised the foundation rock on which the sides of the dam were built. "It is my opinion," Mr. Petit added, "that a dam never should have been constructed at this point. The rock all seems to be largely of the same type."

As the illustrations below show, not only is the center part of the dam still erect but the two generators remain in the canyon firmly resting on their foundations, although the power house itself has been swept completely away.

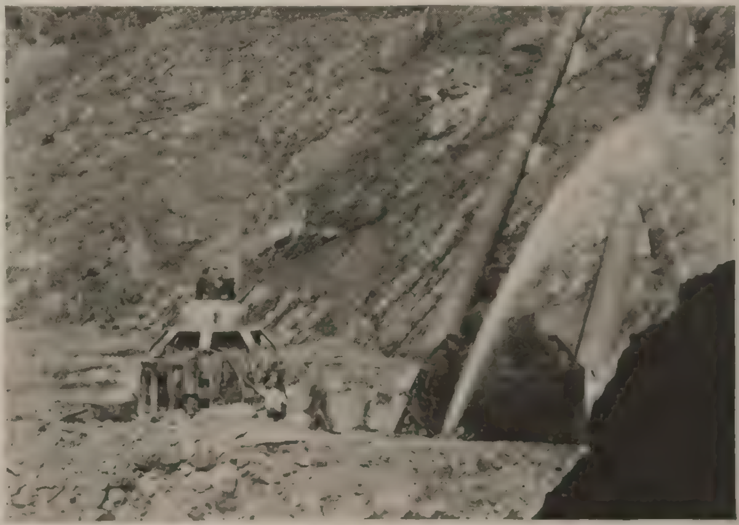
The outstanding feature of the situation is the remarkable manner in which the Southern California Edison Company came to the rescue and made up the deficiency in the city's supply of energy caused by the cessation of service from the city plants. It is a feather in the cap of the company and a proof of the wisdom of large steam reserves in metropolitan centers that ordinarily depend on water power.

From the Southern California Edison Company the following specially prepared account of the first warnings of the disaster and the way in which the company came to the rescue has been received by the ELECTRICAL WORLD:

The first warning of the impending disaster reached the Edison company dispatcher's office at 11:58 p.m., March 12, when one of the company's 60-kv. lines between Saugus and Lancaster went out. Trouble developed at the Saugus substation, and the entire Saugus substation crew was called immediately, which undoubtedly saved the lives of the operators at this substation.



*Center section of dam as it now appears*



*Where plant No. 2 stood—Generators still intact*

*Long Beach steam power house of Southern California Edison Company saves the day*

At 12:02 a.m. both of Los Angeles City's 110-kv. lines went out. At 12:04 a.m., just two minutes later, the Edison company picked up the total city load. At 12:39½ a.m. one of the Edison 220-kv. Big Creek-Los Angeles lines short-circuited. At 12:41 a.m. the second of these lines followed suit.

Up to this time neither the city of Los Angeles nor the Edison dispatcher's office knew what was causing the difficulty. A little before 1 o'clock an assistant patrolman of the Edison company on duty near Saugus called the dispatcher's office over the regular telephone lines and told what had occurred. He had been caught in the edge of the onrushing waters, but managed to escape and reach a telephone so as to get the warning in. Immediately the Edison dispatchers sensed the danger which this onrushing flood offered to the cities and towns in Santa Clara Valley, and calls were put through for all Santa Clara Valley substations.

Casitas substation, just north of Ventura, was the first one in the line, and the story was relayed to the operator in charge with the request that he immediately take steps to notify the chief of police in every one of the cities and towns in the Santa Clara Valley and then notify the Edison district managers in the territory affected. This man called the operators in the Saticoy switching station and other stations throughout the valley, and the story of the impending danger was spread. Undoubtedly many lives were saved by this timely action on the part of the Edison company dispatchers.

### City Orders Generator

Plans of the city of Los Angeles to restore its service are revealed by the fact that the Allis-Chalmers Manufacturing Company at Milwaukee has received a rush order for a generator, waterwheel and transformer to develop 30,000 hp. and to be placed in plant No. 1, located above the St. Francis Dam and not damaged by the flood. The equipment will be ready for shipment in about five months.

Dr. Elwood Mead, the Commissioner of Reclamation, has accepted the chairmanship of a special committee of engineers which will investigate the cause of the failure of the St. Francis Dam. The Secretary of the Interior has extended to Dr. Mead the necessary leave of absence.

## Manufacturing Executives at N.E.M.A. Meeting

Executives of the Policies Division of the National Electrical Manufacturers' Association gathered at the Edgewater Beach Hotel, Chicago, for group and general meetings extending from Wednesday afternoon to Friday morning of last week. Vice-president Clarence L. Collens, who is president of the Reliance Electric & Engineering Company, presided. It was announced that the membership had increased since the last meeting in September from 285 to 310 companies engaged in various branches of electrical manufacture. A code of ethics and sound merchandising principles introduced by N. A. Wolcott, president of the Packard Electric Company, was approved and referred to the board of governors for adoption.

R. J. Russell, president of the Century Electric Company, presented an analysis of present practice among manufacturers in terms of payment, showing the wide diversity in the use of the cash discount both as to the size of the discount allowed and the period taken and also the demoralizing influence of loose methods in regulating payments for goods sold. In a paper on the subject of minimum standard of performance for electrical products, W. S. Rugg of the Westinghouse Electric & Manufacturing Company recommended a minimum standard of performance as one way in which an industry can well serve its customers. Such a standard would be obtained by striking a balance among all the involved elements, such as lowest cost of manufacturing and distribution, greatest adaptability to the purpose for which the apparatus is to be used, greatest durability, lowest cost of maintenance and lowest cost of power to operate it.

The meetings were largely given over to the discussion of various phases of the manufacturing problem, embracing costs and channels of distribution, the possibility of changes in tariff schedule and administration, the need for more comprehensive industry statistics and the purpose of the Electrical Industry Sales Conference.

It was announced during the sessions that eighteen sections of the N.E.M.A. are now regularly collecting statistics on various classes of products and that four more are about to start. The next meeting of the Policies Division will be held at Association Island from July 29 to Aug. 1.

## Savings-Bank Bills Signed by Governor Smith

Governor Smith of New York on Wednesday approved the four bills introduced by the special legislative committee on savings-bank investments, commenting on their importance as he signed them. Among these bills is the one authorizing investments in the bonds of certain electric, gas and telephone companies whose passage by the Legislature was recorded in the ELECTRICAL WORLD last week.

The New York Assembly on Tuesday night passed and sent to the Senate without debate the Sargent water-power bills which carry provisions designed to insure to the state an adequate financial return for whatever private water-power development takes place on the inland streams. The first of these bills provides for the appointment of a commission of three members to be named by the Governor, the Speaker of the Assembly and the President pro tempore of the Senate. The commission is authorized to hold hearings to determine what would be a fair return to the state from private power development on the inland streams. The second of the bills is designed to give protection to the Adirondack resorts chiefly through specifically forbidding the proposed Oxbow reservoir near Tupper Lake, a provision which has been particularly demanded by Saranac Lake and near-by communities.

The proposed commission is required to report to the Legislature what it believes to be a fair rate of return from the private power development. If the rate is approved by the next Legislature, the way will be opened for the development of approximately one-third of the undeveloped hydro-electric power in the state, it is asserted.

The Sargent bills were passed by the Senate in the last-hour rush before adjournment on Thursday and sent to the Governor. His approval, although hoped for, is not yet certain. A premature press report reprinted in these columns last week indicated wrongly that the bills had already been passed and signed.

## Northwest Engineers Meet

*Distribution, Transmission, Lightning and Cable Terminal Failures Chief Problems Discussed at Spokane Gathering*

MEMBERS of the Engineering Section of the Northwest Electric Light and Power Association gathered for their fifth annual midwinter meeting in Spokane, Wash., March 8 and 9. The section, under Chairman O. L. LeFever, has had an active year, and a number of excellent papers were presented. One by M. T. Crawford on the overhead distribution network in Seattle dealt with the experience of the Puget Sound Power & Light Company with a common primary and secondary neutral system. Little trouble has been experienced with transformer outages due to cascading as long as the size of wire in the secondary network has not exceeded No. 4; on the contrary, better voltage regulation, greater economy and more reliable service have resulted, with little inductive interference with telephone service.

The work undertaken by A. O. Austin, Ohio Insulator Company, on high-voltage insulation and lighting was reviewed by H. V. Carpenter, Washington State College, who brought out the fact that Mr. Austin has shown greater economy and better insulator operating characteristics by the use of wooden poles, crossarms and pins and removal of the ground connection from pins than obtains where all-steel construction is used. An illustrated lecture on the Chelan development of the Washington Water Power Company was presented by the hydraulic power committee in which the advantages of the Wahlman gathering intake tube were brought out.

E. C. Stone, chairman Engineering National Section, held that the problem now before engineers of the industry is to secure more system capacity per dollar of investment and stressed the importance of the N.E.L.A. committees as a medium through which to work. A paper on lightning-arrester practice in the Northwest by Richard McKay of the apparatus committee showed little trouble from lightning when arresters are properly applied. The tendency is for bus as well as line protection. Discussion showed that protection resolves itself into a question of proper economic balance between line insulation, apparatus insulation and the cost of protection.

The most important contribution of the underground systems committee was the presentation of results of an investigation which disclosed the cause of failure in certain types of outdoor cable terminals. S. B. Clark showed that terminal failures experienced by one operating company were in large measure caused by internal flashovers caused by unfilled air spaces in vital parts of the terminal subjected to high voltage stresses and into which humid air is breathed. A paper on metal-tank mercury-arc rectifiers for 1,300-volt railway service by John Bankus indicated satisfactory operating results on a 1,500-kw. installation in Portland and greater economy than could be secured by synchronous converters. Success of gaseous rectifiers for railway service seems to presage a much wider application of this system of rectification and its extension to lower voltages.

Through the courtesy of the Washington Water Power Company those attending the meeting were afforded an opportunity to visit power plants and substations and other points of engineering interest in and around Spokane. Trips to the Lake Chelan development were also arranged.

## Arc-Welded Steel Frame

*General Electric Company's Use of This Method in an Addition, Nearly Complete, to Its Philadelphia Plant Described at Engineers' Meeting*

BEFORE a meeting of the American Society of Civil Engineers held at the Engineers' Club, Philadelphia, on March 14 Prof. Frank P. McKibben described the welded steel-frame factory building now being completed by the General Electric Company as an addition to its new plant in Philadelphia.

*Arc-welding a steel-frame building*

The structure is approximately 140 ft. wide, 600 ft. long and 50 ft. high and is erected at Sixty-eighth Street and Elmwood Avenue, Philadelphia. Across the Elmwood Avenue end and connecting to an adjoining building is a high bay or transept spanned by seven of the new welded roof trusses, each having a span of about 72 ft. The main wing of the building has a crane bay over which are twenty of the new trusses, each having a span of about 58 ft. There is also a gallery in an adjacent wing, over which there are twenty welded trusses, each of about 80-ft. span.

The large trusses used to support the roof on the new building are of particular interest because they involve new ideas in truss design. Each truss consists of two parallel lengths of metal latticed together by a system of tension and compression members. The common practice was to construct the trusses with angle iron, but in the new truss the two parallel members or chords are made of H-beams, the tension members are of channel iron and the compression members are H-beams.

The General Electric Company, in order to determine the relative holding values of welded joints, conducted many tests on welded and riveted joints. In one series of tests welded specimens were made by the company and the actual tests were conducted under the direction of Prof. T. R. Lawson of the Rensselaer Polytechnic Institute, Troy, N. Y., in the laboratory of that institution. These tests showed that a ¼-in. fillet will stand a safe allowable load of 2,600 lb. per lineal inch, using four as a factor of safety. Corresponding values for 5/16-in. and ⅜-in. fillets were 2,900 lb. and 3,200 lb. A ¾-in. rivet, the standard size, is estimated to stand a shearing load of 4,500 lb.

In his talk at the Engineers' Club Professor McKibben said that the use of welding resulted in a considerable saving of steel and a consequent reduction in the cost of the steel frame, in the elimination of noise due to riveting and in promoting the electrical industry.

The majority of the welding was done with ⅜-in. fillet welds, 5/16-in fillets being used to some extent at various times. The work is being carried on by the U. G. I. Contracting Company of Philadelphia, general contractor. Harris & Richards, architects of Philadelphia, designed the structure.

## Would Substitute Conferences for District Convention

Subject to the approval of the light and power companies of Minnesota, North Dakota and South Dakota, the executive committee of the North Central Electric Association, which is the geographic division of the National Electric Light Association comprising the three states named, has recommended that the annual convention be superseded by four conferences—accounting, commercial sales, engineering and managerial. This change has been contemplated for some time, and a tryout of two-day conferences was made last year in accounting, commercial sales and engineering. These three sessions drew an attendance of 309, and the response to the new plan was very favorable. Sectional meetings at various points in the district have also been well attended, more than 1,100 taking part. It has been suggested that the association conduct a convention only once every two or three years. A conference of executives and managers will be held at Breezy Point, near Pequot, Minn., June 15 and 16.

The South Dakota electrical conference of the North Central Electric Association was held March 21 at Sioux Falls with much success, speakers from Chicago, Minneapolis and Sioux Falls dealing with engineering and commercial subjects.

## Purchases and Mergers

*Washington Water Power Company Formally Taken Over by American Power & Light—Expansion in Pennsylvania and Other States*

CONTROL of the Washington Water Power Company by the American Power & Light Company of New York was taken over at the annual meeting of the Washington Water Power Company at Spokane last week. Several of the former members of the board were retained, including the executive officers, President D. L. Huntington, General Manager M. W. Birkett and General Counsel Frank T. Post. Sidney Z. Mitchell, president Electric Bond & Share Company, New York, heads the list of trustees and the executive and finance committees. (See ELECTRICAL WORLD, Jan. 21, page 166.)

Applications have been heard before the Pennsylvania Public Service Commission from the Glen Rock Electric Light & Power Company for permission to acquire the East Hopewell Township Light, Heat & Power Company, the Cross Roads Light, Heat & Power Company and the Manheim Township Light, Heat & Power Company, and from the Edison Light & Power Company for permission to acquire the Chanceford Light, Heat & Power Company, the Winterstown Light, Heat & Power Company and the North Hopewell Township Light, Heat & Power Company. All the companies sought by the two would-be purchasers are "paper" concerns, and what is really sought is permission to extend lines over territory contiguous to that now served.

Purchase of seven smaller companies by the Scranton Electric Company has been approved by the Department of State at Harrisburg, Pa., following the Public Service Commission's sanction. The companies purchased are the Carbondale Township Electric Company, Clifford Township Electric Corporation, Greenfield Township Electric Corporation, Laflin Electric Company, Newton Township Electric Corporation, Ransom Township Electric Corporation and Scott Township Electric Corporation.

The St. Lawrence County Utilities, Inc., and the Antwerp Light & Power Company have made a joint application to the New York Public Service Commission for consent to the transfer of the works and system of the latter to the former. The New York Power & Light Corporation has made application to the Public Service Commission for authority to acquire 155 of the 160 outstanding shares of the common stock of the Ticonderoga Electric Light & Power Company. The petition states that the New York company and its subsidiary, the Port Henry Light & Power Company, operate in a territory contiguous to that served by the Ticonderoga company.

An unusual situation has developed as the result of the purchase of 54 per cent of the stock of the Hammond (N. Y.) Light & Power Company by the St. Lawrence County Utilities of Potsdam, N. Y., and of the minority interest by Michael Doyle of Rochester, representing the Oswegatchie Light & Power Company of Gouverneur, N. Y. The minority stockholders, it is reported, gained control of a meeting following the sale, elected the directors and indorsed an expansion program favored by Mr. Doyle, and so far their action has not been reversed.

The Western United Gas & Electric Company, Aurora, Ill., has been authorized to purchase the Western Public Service Company, serving communities along the Burlington Road.

The light and power system at North Lewisburg, Ohio, has been sold to Cleveland capitalists by Frank A. Jordan for $20,000. The purchasers have incorporated as the North Lewisburg Light & Power Company.

The Consumers' Public Service Company, a new corporation with headquarters in Brookfield, Mo., has purchased and merged several utility companies in northern Missouri, including the Browning-Purdin Electric Company, the Laclede Electric Company, the Powersville Electric Light & Power Company and the Rothville-Sumner Electric Company.

Negotiations for the purchase of the Harford County property of the Northern Maryland Power Company by the Consolidated Gas, Electric Light & Power Company of Baltimore have been held up until certain figures shall be verified. Consummation of the deal, however, is expected within a month, according to President H. A. Wagner of the Baltimore utility.

As the result of a unanimous town election, the Southern Public Utilities Company will take over operation of the Walnut Cove (N. C.) electric light plant on June 1.

The Northern States Power Company at Sioux Falls, S. D., has increased its offer of $7,500 for the Canistota (S. D.) municipal electric light and distribution system to $10,000, and the Council will again submit the proposal for sale of the plant at a special election in April.

Milton, Fla., is to vote soon on the ratification of the sale of the town plant to the Gulf Power Company.

Fort Collins, Colo., will probably hold an election on April 3 to decide whether the city shall own and operate its own electric and gas plants. Electricity is now supplied by the Public Service Company of Colorado.

---

## Portland Merger Election Set for April 9

In response to the formal request to the Portland (Ore.) City Council to provide for a special election at which an ordinance will be submitted to the voters on the proposed sale of the Northwestern Electric Company to its competitor, the Portland Electric Power Company, the date of the election has been set as April 9. As a part of the ordinance a new residential schedule is offered to the people of Portland which will bring about an average reduction of 11 per cent in domestic rates. Reduced rates, according to officials, are contingent upon operating economies to be effected through the unification of the companies and will become effective only in the event that the proposal is approved by the voters. As a protection to the public against any increase in rates the ordinance contains a clause stipulating that no increase in rates shall be contemplated or requested during a period of five years. A promise is further made that, if the unification is approved, steps will be taken immediately to establish lower rates for commercial lighting and power and that the maximum rate for commercial lighting shall not exceed 5 cents per kilowatt-hour as against the present top rate of 7 cents.

Following is the new domestic schedule: First 38 kw.-hr. per month, 5 cents per kilowatt-hour; next 32 kw.-hr., 2.8 cents; excess, 1.9 cents. For an installation of 600 watts or less 38 kw.-hr. will be charged for at 5 cents per kilowatt-hour and one additional kilowatt-hour will be sold at 5 cents for each 30 watts of installation in excess of 600 watts. Lighting only will be considered in the determination of the demand. The minimum charge will be $1 per month for lighting customers and $2 per month for cooking and heating customers having a connected load in excess of 2 kw.

---

## Illinois Men Convene

*State Electric Association Takes Part in Two-Day Meeting at Springfield Embracing Three Utility Bodies—Street-Lighting Business a Topic*

GOVERNMENT ownership was characterized as an attempt to transform the state into a benevolent Santa Claus, "doing everything for everybody at no cost to anybody," by Henry Swift Ives, vice-president of the Casualty Information Clearing House, Chicago, who addressed the opening session of a two-day annual convention of the Illinois State Electric, Gas and Street Railway associations held at Springfield on March 14 and 15. He warned the utility delegates that the "old feudal doctrine that the government should support the people" is having a remarkable revival in this country.

Further addresses and discussions in the two morning general sessions of the convention by J. P. Barnes, Oscar H. Fogg, B. J. Mullaney, George R. Jones, Mrs. Marc J. Fowler, Jay G. Mitchell, Charles N. Wheeler, F. S. Armstrong, E. R. Dillavou and others were devoted to considerations of public policy, domestic utilization of utility services, telling the utilities' story to the public, accident prevention and the terminable permit idea. The record of accomplishment of the Illinois Committee on Public Utility Information during the nine years of its life, presented by Mr. Mullaney, showed conclusively that such work is worth while.

The Illinois State Electric Association held its sessions on Wednesday and Thursday afternoons. The report of the industrial relations committee, by W. J. McPherson, summarized the better adjustment of this important factor. R. J. Malcolmson dealt with "Street Lighting as a Source of Revenue." His view of the possibilities of this class of business where there is aggressive sales effort brought out an animated discussion. The paper emphasized the necessity for high-intensity lighting since the fixed-investment charges on any installation are only slightly affected by lamp sizes.

The status of and market for residential refixturing was covered by R. G. Raymond. Methods used and results obtained from fixture sales campaigns by the Ohio Public Service Company and in Chicago by the Electric Association were detailed.

Prof. E. W. Lehmann, who is director of the Illinois project on rural electrification, made his final report, presenting definite data on costs of equipment and energy. The view that rural electric business should be treated separately from other classes was taken by J. Paul Clayton, who pointed out that methods of distribution, rate forms, accounting practices and sales efforts for rural business are different from those for ordinary urban business. A paper by F. B. Sans on progress in connection with superpower transmission in Illinois closed the sessions.

The total convention registration, including all groups, was more than 800, and approximately that number attended the convention dinner, at which Colonel Sidney Storey spoke on the necessity for an American merchant marine.

## Best Oklahoma Meeting

*Manufacturers and Suppliers Have Exhibit—Local "Good-Will" Gatherings to Be Extended Because of Success at Okmulgee and Lawton*

WHAT was declared the most successful convention in the history of the Oklahoma Utilities Association closed at Tulsa on March 15. Besides the events briefly noticed last week (page 573), notable addresses at the general sessions were made by Alexander Forward, managing director American Gas Association; E. K. Hall, vice-president American Telephone & Telegraph Company; J. W. Welsh, general secretary American Electric Railway Association, and others.

The importance of maintaining the public relations and public speaking program was emphasized by W. S. Vivian of Chicago, director of public relations, Middle West Utilities Company. H. S. Bennion, director of engineering of the National Electric Light Association, gave some interesting information on "Interstate Power."

Papers presented in the Electric Light and Power Division were on refrigeration, by R. W. Curran, Bartlesville; rural electrification, by Edwin Kurtz, A. and M. College, Stillwater, and L. S. Reagan, Oklahoma City; developing the small industrial load, by S. I. McElhoes, Oklahoma City; safety methods, by C. H. Meyer, Tulsa; developing power load in the oil fields, by O. A. Jennings, Oklahoma City; rates, by George Mills, Dallas, Tex., and decorative lighting, by A. E. Warner, Oklahoma City.

Five hundred and fifty persons attended the banquet and entertainment on March 14—200 more than last year. Congressman Eaton's address, in which he attacked tendencies to state socialism, as evidenced by endeavors to bring utility companies under public ownership, and defended the utility industries was well received.

Twenty manufacturers and suppliers had exhibits at the convention, almost the entire fifteenth floor of the Mayo Hotel being devoted to this purpose. Establishment of a safety, claims and accident prevention committee to operate within the Public Relations Division of the association was authorized by the executive board. This division announced that it will be more active during the coming year than ever and will continue and extend "good will" meetings like those held recently at Okmulgee and Lawton, where there was a larger registration of outsiders than of public utility men.

New officers to serve until March 14, 1929, are: President, L. W. Scherer, Yale, president of the United Telephone Corporation; first vice-president, H. L. Montgomery, Bartlesville; second vice-president, T. H. Steffens, Sand Springs; treasurer, W. R. Emerson, Oklahoma City; manager (re-elected), E. F. McKay, Oklahoma City. Frank J. Meyer, Oklahoma Gas & Electric Company, was elected chairman of the Electric Light and Power Division, and L. P. Arnold, Public Service Company of Oklahoma, chairman of the Public Relations Division.

## Briefer News

PORT ANGELES, WASH., PLANS CITY POWER PLANT.—Port Angeles, Wash., has filed application for 650 sec.-ft. of water from the Elwha River for a proposed city power and light project capable of developing 10,000 hp. and to cost $750,000.

CENTRAL STATES ELECTRIC COMPANY TO BUILD 100 MILES OF LINE.—Besides increasing the capacity of its Iowa Falls and Armstrong stations, the Central States Electric Company of Cedar Rapids, Iowa, will this year, Vice-president John A. Reed announces, build 100 miles of 33,000-volt, three-phase line, extending from Havelock to Fenton, from Iowa Falls to Eldora, and from Blairsburg to Duncombe and Stratford.

TOKYO CENTRAL-STATION COMPANIES TO BE MERGED ON APRIL 1.—Announcement comes from Japan, where unrestrained competition has prevailed to a large degree in the electric light and power business, that the Tokyo Electric Light Company and the Tokyo Electric Power Company will be merged on April 1. This is regarded as a first and very important step toward establishing the industry in that country on the basis of regulated monopoly.

NORTHWESTERN ONTARIO WILL SOON HAVE 56,000 HP. ADDITIONAL AT SPRUCE FALLS.—Excellent progress on the hydro development of the Spruce Falls Power & Paper Company at Smoky Falls on the Mattagami River, 50 miles north of Kapuskasing, Ontario, is reported, and the plant may be completed by the middle of April. It comprises a power development of 75,000 hp., 50 miles of transmission line and the same length of standard-gage railway between the 600-ton mill and the power site. Four generating units will eventually be installed, of 18,750 hp. each, under a head of 114 ft. The present installation includes three of these.

SAN JUAN RIVER HAS POTENTIAL WATER POWER OF 280,000 HP.—According to the Geological Survey, the San Juan River, called the second largest tributary of the Colorado, has unused resources sufficient to sustain a large development in agriculture and water power. The present power demands are small and are supplied by less than 7,500 hp., generated in four plants. The undeveloped power resources consist of ten power sites capable of yielding, with storage, about 280,000 hp. The report was made by E. C. LaRue.

MOBILE DESIRES TO IMPROVE STREET LIGHTING.—Engineering estimates totaling approximately $270,000 have been compiled and submitted to the Board of City Commissioners of Mobile, Ala., on a proposed extensive ornamental "white-way" street-lighting system for the city. The plan embraced in the survey would require approximately 490 12-ft. standards and 825 10-ft. standards. It would equip practically all the principal streets of the business district with "white-way" lighting and would include about three miles on Government Street, a leading residential thoroughfare.

DUKE COMPANY PLANS STILL ANOTHER CATAWBA RIVER DEVELOPMENT.—With the approaching completion of the Duke Power Company's 56,000 hp. hydro-electric plant at Oxford Shoals, N. C.—the twelfth on the Catawba River—comes a report that the company has already begun preliminary work incident to still another plant on this stream. Details of the project have not been made public, but it is believed that the plant will rank with the largest yet constructed by the company. It will be built just above the Mountain Island plant, near Castonia, completed two or three years ago. No estimates of costs have been announced.

UPSTATE NEW YORK COMPANY PLANS SUBSTANTIAL CONSTRUCTION. — The New York State Gas & Electric Corporation expects to spend $1,672,418 for construction and improvements to its system during 1928. The program includes a 7,500-kw. turbine installation at Ithaca, a 33-kv. transmission line between Liberty and Jeffersonville, a waterwheel at Colliers, an extension from Mount Upton to Gilbertsville and Morris, a transmission line from Walton to Cannonsville and Hancock, substation and substation additions at Walton, Deposit and Hancock, and minor equipment at Delhi.

NEW KENTUCKY TRANSMISSION LINE COMPLETED.—The Kentucky Utilities Company placed in service on March 15 its new 66,000-volt, 36-mile, double-circuit, steel-tower transmission line connecting Morganfield and Earlington, in western Kentucky. The line, which cost nearly $300,000, has transformer substations at both ends and took six months to build. It forms an important link in a transmission loop to be completed in the coming summer, which will include the Earlington, Graham and Paducah generating stations of the Kentucky Utilities and the Grand Tower and Muddy stations of the Central Illinois Public Service Company.

Electric Drills Seek More Oil 7,600 Ft. Beneath Surface.—What is pronounced the most remarkable test yet made of the use of electricity in oil-well drilling is that of the Texas Oil & Land Company on land owned by the University of Texas in the Big Lake field. When the report was received this well was past the 7,600-ft. mark and was being sunk still deeper. But for the adaptability of electric motors in handling the drilling tools it would have been impossible to drill the well to so great a depth, it is asserted. The electric motors are so efficient that the tools can be raised, the bailer run twice and the tools run back on bottom in one hour and thirty minutes.

Three-Cornered Agreement Over Delco-Remy Service Adopted. — The difficulty noted on Feb. 11 (page 324) over additional power and standby service for the Delco-Remy plants at Anderson, Ind., which employ seven thousand persons, has been adjusted by a six-year contract with the Indiana General Service Company for all power in excess of what the municipal plant can furnish. The power company will build a 132-kv. transmission line to the east edge of the city and erect a substation, while Anderson will build lines from the corporation limits to the Delco-Remy plants and also to the municipal plant. Whenever the city takes energy from the Indiana General Service Company the latter will be repaid from the municipal plant.

Montreal Investigates Power Possibilities of Aqueduct and of Garbage Incinerators.—The possibility of utilizing the aqueduct in Montreal, where electric pumping has been substituted for steam, to furnish light and power is being investigated. The city spends annually more than $750,000 for electrical energy and the indicated saving is thought worth while. The aqueduct is about seven miles long and the installation of a city power system would not only provide power for it but also for the sewer department, street lighting and civic building. Engineers are also estimating the available power development from the combustion of garbage at incineration plants which the city expects to erect this year.

Illuminating Engineers of the World to Tour American Cities.—An International Congress on Illumination, to bring together leaders in the field of lighting from all parts of the world, is to be held in the United States in September. The event will open on Sept. 7 with a tour by the foreign delegates to various American cities, will include the twenty-second annual convention of the Illuminating Engineering Society at Toronto on Sept. 17-20 and will close with the eighth session of the International Commission on Illumination, to be held at Saranac Inn, N. Y., from Sept. 22 to 28. The arrangements are being made under the auspices of the Illuminating Engineering Society and the United States National Committee of the International Commission on Illumination. John W. Lieb, vice-president New York Edison Company, is serving as chairman of the reception committee. Julius Daniels, Edison Electric Illuminating Company of Boston, is chairman of the executive committee in charge of arrangements.

Sixty Thousand Visit New Orleans Electrical Exposition. — Almost sixty thousand persons visited the electrical exposition sponsored by the Electrical League of New Orleans and held at the Delgado Trades School early this month. Many manufacturers and electrical companies had booths, and the lighting was an especially attractive feature. Credit for the success scored is due in large part to the arrangement committee, of which W. E. Clement, commercial manager New Orleans Public Service, Inc., was general chairman. The illustration shows the booth of the company just named.

Application to Missouri Commission for Bagnell Site Temporarily Withdrawn. — The Missouri Hydro-Electric Power Company on March 13 withdrew for the present its application for an extension of the certificate of convenience and necessity granted it by the Missouri Public Service Commission two years ago to construct a dam and power plant on the Osage River near Bagnell. Protests against the project were made by residents of Camden and Benton Counties, and especially by citizens of the village of Linn Creek, which, it was said, would be obliterated. It was stated that the federal license issued to Walter Cravens, former head of the company in Deecmber, 1925, had been transferred to the company. The estimated cost of this project is $19,000,000, and, as stated on Feb. 18 (page 369), Stone & Webster and the Union Electric Light & Power Company may possibly become actively interested in it.

A.S.M.E.'s Tentative Plan for Fuel Research.—A preliminary plan for research in fuels, as approved by the main research committee of the American Society of Mechanical Engineers, has been issued. This research is to be carried on as one of the society's activities, and the chairman of the special committee having the research in charge—F. R. Wadleigh, 1 Broadway, New York—solicits suggestions and assistance from all interested. A booklet, "Research Activities," issued by the society, is available.

Municipal Ownership in Missouri.—Voters of Kennett, in southern Missouri, with but nine dissenting votes, on March 14 decided to build and operate a municipal light and power plant and distribution system, although on the day before the election the Arkansas-Missouri Power Company, which has been serving the town, announced a substantial reduction in its rates. The town has three proposals under consideration, several plant-equipment concerns having offered to install equipment and accept payment out of the plant's profits if the town will furnish the building. Trenton, in the other end of the state, has a municipal plant under consideration, its estimates being based on the cost of the one in Chillicothe, Mo.

Extension of Bureau of Standards' Control of Weights and Measures Opposed.—The American Institute of Weights and Measures is out in opposition to a bill now before a committee of the House of Representatives and designed to empower the Bureau of Standards to approve or disapprove all weighing and measuring devices or mechanisms used in the country. The American Institute of Weights and Measures recommends that every one concerned take steps to inform himself regarding the provisions of this bill. It accuses the Bureau of Standards of seeking authority to police every conceivable kind of device in use for producing articles dimensioned in terms of the standards of weight and measure. Micrometers, gages and meters of every kind are mentioned among the apparatus which the protesters think would automatically be included in the provisions of the bill.

American Electrochemical Society's Spring Program at Bridgeport. —Dr. George W. Vinal of the Bureau of Standards will be in charge of the first session of the American Electrochemical Society's spring meeting at Bridgeport, Conn., on April 26-28, the symposium subject being "Chemical Production of Electricity" and covering electrolytic rectifiers, storage batteries, gas cells, dry cells and standard cells. The evening will be devoted to an illustrated lecture on the "Refraction of X-Rays in Elements and Compounds," by Prof. Bergen Davis of Columbia University. On Friday morning a discussion on industrial electric heating, held jointly with the National Electric Light Association, will be participated in by R. M. Keeney, John L. Christie, R. E. Talley and others. A new film on "Electric Heat in Industry" will be presented. Dr. B. D. Saklatwalla, chairman of the electrothermic division, will preside at an informal round-table discussion on refractories for electric brass melting. Saturday morning's session, in charge of Prof. E. M. Baker, will deal with the plating of silver, nickel, brass and chromium.

## *Coming Meetings*

[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]

Southwestern Division, N. E. L. A.—Edgewater Gulf Hotel, Biloxi, Miss., April 3-5. S. J. Ballinger, San Antonio Public Service Company, San Antonio, Tex.

Nebraska Section, N. E. L. A.—Omaha, April 4 and 5. T. E. Browne, 1527 Sharpe Bldg., Lincoln.

Southeastern Division, N. E. L. A.—Miami, Fla., April 11-14. C. M. Kilian, 207 Bona Allen Bldg., Atlanta.

American Institute of Electrical Engineers — Baltimore regional meeting, April 17-19; New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities—Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A.—Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

# Commission Rulings

Condemnation of Land by Public Utility Includes Coal and Fireclay Beneath It.—The Duquesne Light Company in condemning a parcel of ground on which to erect a substation was refused permission by the owner to acquire coal and fireclay underlying it. In view of the danger of subsidence of the plant if the underlying strata were removed, the company appealed to the Public Service Commission of Pennsylvania, which sustained its claim to the subsurface as well as the surface of the plot.

Nebraska Commission Limits Bond Issue.—Passing on an application from the Central West Public Service Company of Nebraska for approval of an issue of 6 per cent 30-year bonds in the sum of $500,000, the Nebraska State Railway Commission holds that no bonds should be issued in excess of 75 per cent of the present value of the property offered as security and that in ascertaining the basis of such valuation there must be eliminated the working capital and going-concern value as well as any value placed on a water right acquired by purchase. It, therefore, declined to approve any issue in excess of $400,000. All the company's stock is owned by the Central West of Delaware. None of the bonds is to be sold to the public, but they will be substituted for stock now used as collateral for a mortgage of the parent company.

Georgia Commission on Supreme Court Valuation Dicta and on Combination Companies.—In handing down a decision in a street-railway fare dispute involving the Georgia Power Company, the Public Service Commission of Georgia said: "The Supreme Court of the United States, to our mind, has not been as definite in prescribing rules as a guide for arriving at a fair value as a proper rate base as we believe should have been the case. However, considering its expressions on this subject as a whole, it is very clear that it leans more to the reproduction-cost theory than to any other method. It is our belief that a strict adherence to the reproduction-cost theory would not be best for the company or the citizens it serves. Conditions could happen, as they have happened in the past, which to apply to such a method would work disaster for the company as well as hardship on the public. Such a theory if applied in the last half of 1914, 1915 and 1916 would have bankrupted most of the companies throughout the country. . . . The commission has consistently held that where different classes of utility service are being rendered by one company, as far as practicable these properties should be segregated and the patrons of each class should bear their part of the burden of producing a return on the fair value of such property as is devoted to their use. To do otherwise would have the effect of creating discriminations between the different classes of patrons of the company. In the instant case it is true that many car riders do not use electric light or gas, whereas, on the other hand, many patrons of the gas and electric departments rarely if ever use the street-car service. It therefore follows that if the street-railway department is not earning a reasonable return on the fair value of its property, it would be a discrimination and unfair to the users of gas and electricity to require them to pay excessive rates to make up losses in the railway department. . . . If the street-railway property is to be treated in conjunction with the gas and light and power property, people throughout the state would be called upon to contribute to the support of the street-railway property, although comparatively few would ever have need for its use. Such a theory is fundamentally unsound."

Petition by Consumers for Increased Monthly Charge Dismissed.—The Indiana Public Service Commission has dismissed a petition from most of the customers of the Madison Light & Power Company asking that the minimum monthly charge be increased as an offset to a reduced lighting rate offered by the company. The commission said that the expense of the hearing required by law would be greater than the relative advantage that the customers were seeking.

# Recent Court Decisions

Railroad Found Liable to Power Company for Bridge Constructed by Latter.—The United States Court at Charlotte, N. C., has decided that the Southern Railway owes the Blue Ridge Power Company $260,000 as reimbursement for expenses growing out of the construction of a bridge across Green River just above Saluda on a division of the Southern Railway. The power company, the decision explains, replaced a wooden trestle by a concrete bridge after it had asked for permission to construct a dam that would end the usefulness of the former trestle. The court found that the new bridge had benefited both companies equally and that the railway should reimburse the power company. Appeal will be taken.

Utility Confined by State Commission to Certain Part of Divided Territory Not Deprived of Property Without Due Process of Law.—In sustaining the decision of the New Jersey Board of Public Utility Commissioners fixing a territorial boundary in the borough of Spring Lake for the observance of rival light and power companies (Electrical World, Feb. 18, page 374), the New Jersey Supreme Court said (Eastern New Jersey Power Company vs. Board) that it could find no merit in the contention that the order deprived the plaintiff of property without due process of law. "It is manifest," said the court, "that an electric light company which undertakes to furnish a municipality with lighting for its streets or public buildings and enters into a contract with such municipality, for either a short or long term of years, to that end necessarily takes into consideration the cost of furnishing adequate equipment for the purpose designed and that a time will come when the term of the contract will expire and the municipality may not see fit to renew the contract. . . . Neither of the companies has a right in perpetuity to furnish the electric lighting for the borough. . . . We can discern nothing in the order of the board which attempts to do anything more than to regulate how the two electric light companies shall exercise their franchises." (140 At. 258.)*

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

# News About Men of the Industry

C. W. Wallace has been elected a director of the Toledo Edison Company.

J. E. Webster has been appointed chief plant engineer of the Westinghouse Electric & Manufacturing Company at East Pittsburgh, Pa.

G. D. Horne, district operating supervisor of the Central Hudson Gas & Electric Company at Beacon, N. Y., has been transferred to Poughkeepsie as division engineer.

J. M. Bennett has been appointed manager of the department of public relations recently organized by the Philadelphia Electric Company for the handling of all matters relating to publicity and advertising.

P. C. Brooks, president of E. & T. Fairbanks & Company and vice-president of the Canadian Fairbanks-Morse Company, Ltd., has been made a vice-president of Fairbanks, Morse & Company, Chicago.

Sebastian L. de Ferranti, past-president of the Institution of Electrical Engineers of Great Britain, a pioneer in high-tension transmission and well known in this country and throughout Europe, has been elected a fellow of University College, London.

H. C. Blackwell, president of the Union Gas & Electric Company, Cincinnati, has been named chairman of the Cincinnati Safety Committee organized by the Industrial Commission of Ohio. Mr. Blackwell has long been active in civic affairs in Cincinnati, at the present time being president of the Cincinnati Chamber of Commerce.

Lewis Buckley Stillwell of New York has been re-elected chairman of the Engineering Foundation, the research organization of the national engineering societies. Mr. Stillwell, who enters upon his fourth term, is past-president of the American Institute of Electrical Engineers and the American Institute of Consulting Engineers. He is a native of Pennsylvania and a graduate of Lehigh University.

Frank Milhollan, chairman of the Board of Railroad Commissioners of North Dakota, has resigned, effective April 1, to become president and general manager of the Central West Public Service Company. Ben Larkin, who has been a member of the board for more than two years, has been selected by Governor Sorlie to succeed Mr. Milhollan.

Edward B. Myers, formerly assistant to J. T. Hutchings, vice-president in charge of engineering development of the United Gas Improvement Company, Philadelphia, has been named assistant to the president. Mr. Myers has been associated with the U.G.I. or its subsidiaries for 24 years, starting as a cadet engineer with the city district of the Philadelphia Gas Works in 1904. In 1911 he became associated with the engineering department of the Northern Indiana Gas & Electric Company, South Bend, Ind., returning to Philadelphia two years later.

## *Ballard Now President of Southern California Edison*

Russell H. Ballard, executive vice-president and general manager of the Southern California Edison Company for the past eight years, was elected president of that company at the recent meeting of the board of directors, in succession to John B. Miller, who retains the chairmanship of the board. The selection of Mr. Ballard is the logical and expected result of his services to the company in the years during which it has grown from the status of a comparatively small organization exploiting the water-power resources of southern California to one of the greatest metropolitan central stations in the land, with immense steam plants supplementing its hydro installations and with reserve steam equipment capable of picking up the 93,000-kw. load dropped by the municipal plants in the recent disaster. With experience in commercial and financial work for power companies in the East, South, Middle West and Mountain States, Mr. Ballard became auditor of the Southern California Edison Company in 1904 and progressed steadily to the posts of assistant general manager, vice-president and assistant general manager, and vice-president and general manager. The last-named office he assumed in 1920.

*R. H. Ballard*

Mr. Ballard's sphere, however, is not merely territorial. His election to the presidency of the National Electric Light Association in 1919 brought him into national prominence in the light and power world, and the outstanding services he rendered during his occupancy of that office have had lasting results. With the able assistance of M. H. Aylesworth, whom he installed as executive manager, he remodeled the structure of the association, giving it the form it still retains. By extensive speaking tours and participation in the conventions of the geographic divisions he reawakened the interest of industry executives in association activities, and the methods adopted in his term are still in favor at headquarters Mr. Ballard's own interest and participation in national work continue unabated.

D. B. Ranno has been named superintendent of the Schuylkill division of the Philadelphia Suburban-Counties Gas & Electric Company with headquarters at Norristown and R. R. Daniels has been appointed superintendent of electric production of the Schuylkill division.

John F. Carney has resigned as treasurer of the Utica (N. Y.) Gas & Electric Company after 26 years of service to become affiliated with Stone, Seymour & Company, Inc., investment brokers of New York. Mr. Carney will continue to reside at Utica.

Lee J. Ruf has been appointed power plant superintendent of the Nebraska Power Company to succeed the late Edward McDonald. Mr. Ruf formerly was identified with the Omaha Electric Light & Power Company before that property was taken over by the Nebraska Power Company.

J. M. Flanigen, who was appointed division superintendent of the Georgia Power Company in Rome last December, has been recently transferred to the company's office in Atlanta. Mr. Flanigen was formerly connected with the Alliance division of the Ohio Public Service Company.

M. H. Montross has been appointed general superintendent of the Wisconsin Valley Electric Company, Wausau, Wis. Mr. Montross was formely divisional manager at Stevens Point and prior to his connection with the Wisconsin Valley Electric Company he was associated with the Gary (Ind.) Heat, Light & Power Company and the Toledo Edison Company.

Richard Lincoln has been appointed superintendent of the appliance department of the Edison Electric Illuminating Company of Boston, succeeding C. Ernest Greenwood, who recently resigned to become commercial manager of the National Electric Light Association. Mr. Lincoln's early career began in the electric railway construction field in Massachusetts and Virginia. He entered the collection department of the Boston Edison Company in 1909, was transferred to the sales department in 1916 and for three years was in charge of merchandise sales in the Framingham district. In 1919 he was promoted to be assistant superintendent of the appliance department, and will now be in charge of all merchandising activities of the company. He is a past chairman of the merchandising bureau of the Commercial Section, New England Division, N.E.L.A.

W. C. Gilman, formerly connected with the commercial department of the Central Hudson Gas & Electric Company, Poughkeepsie, N. Y., is now identified with the Carolina Power & Light Company at Raleigh, N. C.

Robert J. Deneen and Frederic Attwood were elected vice-presidents of the Ohio Brass Company at a meeting of the board of directors held Feb. 7, 1928. Mr. Deneen is in charge of the company's sales activities in the Chicago district, while Mr. Attwood is in New York in charge of the Eastern sales district.

Robert W. Purchas, formerly purchasing agent for the Northern States Power Company in Minneapolis, has been appointed assistant to Vice-President H. W. Fuller, head of the engineering and construction department of the Byllesby Engineering & Management Corporation, Chicago. Mr. Purchas served as purchasing agent of the Northern States company for eight years.

R. H. Denman has been assigned to the Albany district of the New York Power & Light Corporation in the capacity of rural expert. Mr. Denman's duties will include the extending of electrical service on the farms in the Albany district. Mr. Denman is a graduate of Cornell University in agricultural engineering.

A. E. Kaiser, who has been associated with the Westinghouse Electric & Manufacturing Company since 1895, has been appointed director of production for all works. During his period of service with the company he had a wide range of experience. After serving in various departments, he was appointed assistant director of production in 1912 and in 1919 he was promoted to be director of production of the East Pittsburgh works. Later he was made assistant works manager of the East Pittsburgh works.

Guy P. Norton, a vice-president of the Miller Company, Meriden, Conn., was elected a director of that company at a meeting of the stockholders held March 8. Mr. Norton first became engaged in the manufacture of lighting fixtures in 1898. He helped perfect the first Duplex-a-lite organization, which became the Duplex Lighting Works of the General Electric Company in 1918. In 1924 this company was sold to the Miller Company and a year later Mr. Norton was made a vice-president of the company and placed in charge of Duplex-a-lite sales.

Leon M. Brockway has affiliated himself with the New England Power System, Worcester, Mass., where he will co-ordinate the office and field engineering with the hydraulic development construction work. Seventeen years ago Mr. Brockway was identified with the New England system as resident engineer on the Shelburne Falls Development, but he left in 1913 to enter the employ of the Electric Bond & Share Company. Subsequent connections followed with the Ontario Power Company, the Power Construction Company, the Atlantic Loading Company, and Conway & Reid, general contractors, before he returned to the New England Power System.

E. S. Zuck, formerly rate engineer of the Penn-Ohio System, is now power engineer of the United Gas Improvement Company, Philadelphia. Mr. Zuck's resignation brought to a close an association which covered a period of nine years, during which he served as power salesman, power sales engineer and finally as rate engineer. Before affiliating himself with the Penn-Ohio System Mr. Zuck had been connected with the Western Electric Company at Cleveland, the Electric Furnace Company at Salem and the Westinghouse Electric & Manufacturing Company at East Pittsburgh.

Earl L. Carter has resigned as chief engineer of the Indiana Public Service Commission effective April 1, in order to enter private consulting work. In his position as engineer for the commission, one of his principal duties was to fix valuations of utilities for rate-making purposes. He entered the service of the commission in 1917 as assistant engineer and became chief engineer six years ago. He graduated from Purdue University in 1914 and received a master's degree in 1918. Harry V. Wenger, formerly a member of the engineering staff of the commission, has been selected as Mr. Carter's successor. Mr. Wenger took a position with the commission in 1917 and also is a graduate of Purdue. He served on the commission engineering staff about three and one-half years. He left in 1923 after having been elected chief engineer of the railroad commission of South Dakota. Later he returned to Indianapolis and has engaged in private engineering work since that time.

## Obituary

R. D. Pike, general purchasing agent for the Pennsylvania-Ohio Power & Light Company, died at his home in Youngstown, Ohio, March 12. Mr. Pike had been with the company for fourteen years. He was 44 years of age.

Clifton H. Dwinnell, president of the First National Bank of Boston, died at his residence in that city March 13. He was 54 years of age and was graduated in electrical engineering in 1894 from the Worcester Polytechnic Institute, of which corporation he was a member.

Dr. Thomas B. Freas, noted inventor and professor of chemistry at Columbia University, New York, died at Lenox Hill Hospital, after a short illness, March 15. Professor Freas was recognized as an authority on thermodynamics and had invented thermostats, ovens, ventilating apparatus and other laboratory necessities. He was a member of the American Electrochemical Society, the American Association for the Advancement of Science and other technical societies.

L. W. Llewellyn, president of the Walsh & Weidner Boiler Company, Chattanooga, Tenn., died March 18. Mr. Llewellyn had been incapacitated, due to heart trouble, since August, 1926. Besides being president of the Walsh & Weidner company he was also president of the Chattanooga Implement Manufacturing Corporation, treasurer of the Provident Life Insurance Company of Chattanooga and a member of the board of directors of a number of prominent enterprises around Chattanooga.

Conrad Hubert, chairman of the board of directors of the Yale Electric Corporation, New York, died March 14 at Cannes, France, in his seventieth year. Mr. Hubert organized the Ever-Ready Battery Company and held the presidency prior to the sale of the business to the National Carbon Company, about ten years ago. He subsequently purchased a majority of the stock of the Yale Electric Corporation, which manufactures flashlights and electric batteries for automobiles and radios. Mr. Hubert was interested in other industrial enterprises.

Ralph Blakeman, manager of the Public Service Company of Colorado at Louisville, Colo., died suddenly at Windsor, Colo., Feb. 29.

Albert W. Flor, who had been associated with the Electric Bond & Share Company for the past fourteen years, died Feb. 6 in his 42d year. After extensive experience in the government service, Mr. Flor joined the Utah Power & Light Company in Salt Lake City, previous to removing to New York. Among the executives whom he assisted were C. E. Groesbeck, E. K. Hall and F. B. Odlum.

Samuel F. Moran, well known public utilities lawyer, died March 20 at St. Vincent's Hospital, New York, of chronic intestinal nephritis. Mr. Moran was admitted to the New York bar in 1903 and was assistant corporation counsel of Buffalo from 1906 to 1909. For many years he specialized in public utility law. Among the companies for which he was attorney are the Brooklyn Edison Company, the Kings County Lighting Company, the Cohoes Power & Light Corporation and the Citizens Water Supply Company of Newtown, New York. In 1919 he had charge of the merger of the electric corporations heretofore operating in Brooklyn which formed the Brooklyn Edison Company and since that time he had represented that corporation in all proceedings involved in stock and bond issues. Mr. Moran was 53 years of age.

# Financial and Statistical News

## *Keen Investment Demand*
## *Stocks at New High Levels*
## *Fewer New Issues Sold*

KEEN investment demand for public utility securities, combined with a sharp reduction in new issues, has resulted in a smaller visible supply of these securities. New power and light issues are now running between 40 and 50 per cent below last year. Another factor in the situation is the passage of the savings bank investment act in New York State. In addition to the actual legalization of a large volume of issues, the act will undoubtedly affect the trend of legislation elsewhere, in some degree at least.

The market for power and light securities has been exceedingly firm during the past few days. Averages are now at new high levels and the trend is distinctly upward. During the past week Edison of Boston went up fourteen points, to 272; Pacific Gas & Electric rose thirteen points, to 192; Public Service of New Jersey reached a new high of 138, and Southeastern Power & Light a new high of 47½; North American common reached a high of 67, and Electric Investors a high for the present movement of 48. These are only a few examples of the price rises in common stocks. A number of preferred issues have made substantial gains also. Buying of these issues by investment trusts is reported to be unusually active.

## Company Reports

| Name of Company | Gross Earnings Twelve Months Ended Jan. 31 1928 | 1927 |
|---|---|---|
| American Power & Light subs.* | $62,786,765 | $59,411,694 |
| American Wtr. Wks. & Elec. | 48,866,582 | 45,790,401 |
| Idaho Power* | 3,146,573 | 2,869,474 |
| Kansas City Power & Lt.* | 12,502,403 | 10,877,859 |

| New Orleans Public Service, Inc.* | 18,442,108 | 17,624,514 |
| Public Service Company of New Hampshire & subs. | 3,631,593 | 3,469,173 |

* Twelve months ended Dec. 31, 1927.

## North Carolina Developments in 1928

According to a recent statement of the Department of Conservation and Development of North Carolina new hydro developments totaling 295,000 hp. are now under construction. It is rumored that one of the large power companies will construct a 100,000-hp. steam station during the year. The Carolina Power & Light Company expects to begin construction on 110,000-volt transmission lines from Sanford to Cape Fear Station (10.7 miles), from Norwood to connect with existing lines (16 miles), from Canton to Greenville (55 miles), from Canton to Asheville (20 miles) and from Moncure to Sanford (37 miles), a total of 138.7 miles. This company completed during the present year the first 132,000-volt line in the state, leading from Roxboro to Danville, Va. The Virginia Electric & Power Company has planned to construct 32 miles of 33,000-volt lines during the year in the northeastern part of the state.

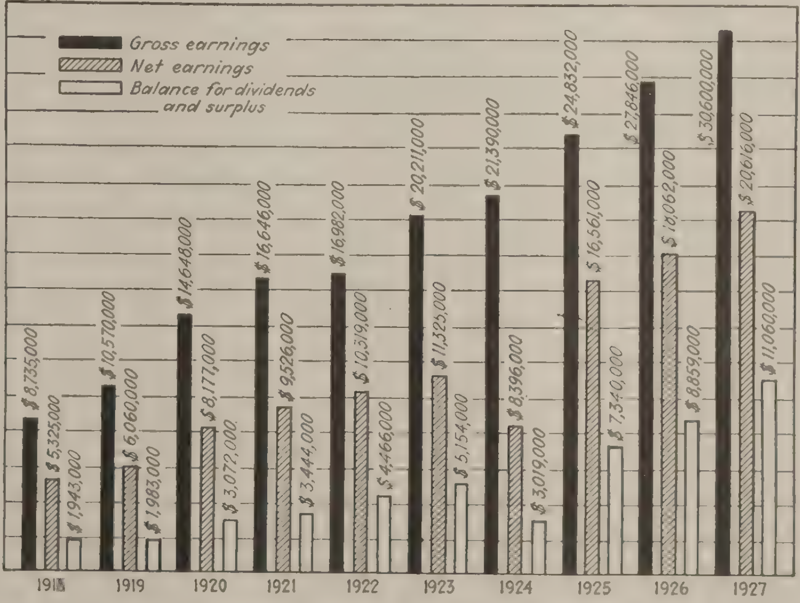
It is probable that during the year one or more of the larger municipal steam plants in the east will pass into the control of private interests, and this in turn will probably lead to new high-voltage lines being built in that section.

Altogether 1928 promises to be a year of considerable activity in power development in the state, and the ever-increasing power demand of new industries and expansion of existing activities will continue to be met by added power facilities adequate to supply whatever requirement exists.

## Southern California Edison Reports Prosperous Year

IN SPITE of the reduction in lighting rates, which had been in force during the last six months of 1927, gross earnings of the Southern California Edison Company totaled $30,600,637, an increase of 9.9 per cent over the preceding year, when gross earnings amounted to $27,846,518. Net earnings amounted to $20,615,686, an increase of 14 per cent, and were equivalent to 3.54 times annual interest requirements. The coupling of these financial figures with the operating statistics makes a picture which reveals the satisfactory results of the year's operations. Sales of electric energy aggregated 1,877,204,517 kw.-hr. The maximum demand of over 600,000 hp. exceeded all previous records. Due to abundant water, favorable fuel costs and economies in operation, a reduction of $390,429, or 5.3 per cent, was effected in operating expenses. Taxes paid to federal, state and local governments amounted to $3,076,252. According to the report under review the year was also noteworthy with respect to the additional load connected, which aggregated 218,417 hp., the greatest amount of load taken on the lines in any twelve-month period of the company's history.

The company's financing program during the year included the sale in January of an additional issue of 25-year refunding mortgage bonds amounting to $15,000,000 and the offering in September of refunding mortgage 25-year bonds amounting to $30,000,000. Part of the proceeds of the first issue was used to retire outstanding notes and maturing debentures and proceeds from the second issue provided funds for the retirement of 6 per cent refunding mortgage bonds due in 1943. As a result of this new financing the company effected a considerable annual saving in fixed charges and materially improved the credit position of its subsequent bond issues. At the present time, in addition



*Southern California Edison earnings show substantial gain* to the 5's of 1951 and 5's of 1952 mentioned above, the funded debt includes general and refunding mortgage bonds due Feb. 1, 1944, paying 5 per cent interest, amounting to $10,000,000, and 5½ per cent interest, amounting to $10,225,000. Also there are outstanding general mortgage 5 per cent 30-year gold bonds, due Nov. 1, 1939, totaling $13,360,000. Underlying bonds complete the set-up with a total of $15,412,700. The entire funded debt amounts to $134,971,700. The year closed with no floating debt against the company and with $5,023,599 cash on hand and in banks. Total assets as of Dec. 31, 1927, amounted to $309,837,988, an increase of $41,630,345 during the year.

Since 1917 the company's junior financing has been accomplished principally through the sale of its capital stocks to its consumers and the local public. At the close of the year 1927 individual stockholders numbered 114,150, with holdings averaging 50.3 shares each. The adoption of this customer-ownership plan, together with voluntary reductions in rates, is largely responsible for the cordial relations existing between the company and its customers. The trend of maximum rates for energy since 1920 is shown in the accompanying table.

| | Cents Per Kw.-Hr. |
|---|---|
| 1920 | 10.16 |
| 1921 | 9 |
| 1922 | 7.92 |
| 1923 | 6.5 |
| 1927 | 5.6 |

In closing the report, John B. Miller, president, says: "The company commands a strong financial position in the credit market and enjoys the confidence and support of the public in its territory. Physical properties are in excellent condition, covered by insurance against fire, earthquake, casualty and other contingencies, and proper provision has been made for depreciation and replacements."

AMERICAN SUPERPOWER INCREASES STOCK.—At a general meeting of stockholders of the American Superpower Corporation held March 9 an increase in the class A stock from 600,000 to 1,000,000 shares was authorized, as well as an increase in first preferred stock from 200,000 to 400,000 shares.

## Bonds Called in March

Among the securities of electric light and power companies called for payment in advance of maturity are the following:

| Issue | Due | Amount |
|---|---|---|
| Toledo Edison, 7s | 1941 | $13,500,000 |
| Ohio Power, 6s | 1953 | 10,000,000 |
| Western States Gas & Elec., 6s | 1947 | 8,850,000 |
| Western States Gas & Elec., 6s | 1937 | 5,000,000 |
| National Electric Power, 5s | 1945 | 8,662,500 |
| Pennsylvania Water & Power, 5½s | 1953 | 3,000,000 |
| Holtwood Power, 6s | 1954 | 2,750,000 |
| Queensborough Gas & Elec., 6s | 1953 | 2,000,000 |
| Coast Valley Gas & Electric, 6s | 1952 | 1,813,000 |
| Quincy Gas, Elec. & Heating, 5s | 1935 | 1,400,000 |
| Eastern Wisconsin Electric, 5s | 1947 | 1,024,500 |
| Western Pwr. Lt. & Tele. 6½s | 1929 | 1,000,000 |
| Northeastern Iowa Power, 6s | 1929 | 800,500 |
| Northeastern Iowa Power, 5s | 1928 | 300,000 |
| Ottawa Light, Heat & Power, 6s | 1953 | 650,000 |
| Central States Power & Lt., 5½s | 1928 | 250,000 |
| Minnesota Elec. Distributing, 7s | 1934 | 182,000 |
| Public Service of N. J., 6s | 1944 | 19,595,000 |
| Public Service of N. J., 5½s | 1956 | 15,000,000 |
| Interstate Public Service, 6s | 1948 | 8,551,900 |
| Interstate Public Service, 5½s | 1950 | 2,838,500 |
| Central States Electric, 6s | 1945 | 9,691,000 |
| Beloit Water, Gas & Electric, 5s* | 1937 | 30,000 |
| Sandusky Gas & Electric, 5s* | 1945 | 13,000 |

* Not entire issues.

## Illinois Power & Light to Retire Preferred Stock

It is proposed by the Illinois Power & Light Corporation, Chicago, Ill., to call and retire all of its 7 per cent cumulative preferred stock. In order to raise funds with which to accomplish this, the corporation proposed to create and sell a new class of preferred stock. This class will be without par value, will be preferred in involuntary liquidation at $100 per share and in voluntary liquidation at $110 per share, plus accrued dividends. The call price will also be $110 per share. The call price of the existing 6 per cent preferred stock, as well as its price on voluntary liquidation, will be $110. Otherwise, the new class will have substantially the same charter protection as the existing preferred stock. This proposed refinancing plan is subject to action of the stockholders at a meeting to be held for that purpose on April 23 and to the approval of the Illinois Commerce Commission.

RECENT LISTINGS.—The New York Stock Exchange has authorized the listing of 1,136,344 shares of second preferred stock, series A, of American & Foreign Power Company outstanding and 633,155 shares of second preferred, series A, to be added to the list on official notice of issuance, making the total amount of second preferred stock, series A, applied for 1,769,499 shares. There have also been recently authorized for listing 250,000 additional shares (no par value) preferred stock of the North American Edison Company on official notice of issuance upon conversion of its 5 per cent debentures, series A, due March 1, 1957, making a total of 450,000 shares of preferred stock applied for. Additional common stock of the Pacific Gas & Electric Company has been authorized for listing on the New York Stock Exchange to the amount of $6,458,350, making the total amount applied for $71,191,150. The listing of $60,000,000 in 5 per cent secured gold bonds, series A, of the Philadelphia Company has been authorized for listing on the New York Stock Exchange, as has also $45,000,000 in first and refunding mortgage gold bonds, 4½ per cent series, of the Public Service Electric & Gas Company.

SHAWINIGAN WATER & POWER INCREASES STOCK.—At a special meeting of the shareholders of the Shawinigan

Water & Power Company held Feb. 21, the capital stock was increased from 1,200,000 shares without par value to 1,600,000 share without par value and at a subsequent meeting of the directors an issue of stock, without par value, to the shareholders was authorized at a price of $50 per share on the basis of one share of new stock for each four shares of the outstanding holdings of record March 26. Rights expire May 1.

## New Capital Issues

First lien 5½ per cent gold bonds, series B, of the United Public Utilities Company were offered to the amount of $3,750,000, at 97¾ and interest, yielding about 5.70 per cent. These bonds will mature April 1, 1947. The United Public Utilities Company, a New Jersey corporation, controls subsidiaries operating in a group of communities in Ohio, Indiana, North Dakota, South Dakota, Alabama and Louisiana.

The American Commonwealths Power Corporation issued 50,000 shares of first preferred stock, $6.50 dividend series, at 95 and accrued dividend, yielding about 6.85 per cent. Proceeds from the sale of the stock will be used for the acquisition of stock of certain companies and for other corporate purposes.

New York Utility Changes Name.—The New York State Gas & Electric Corporation, Ithaca, N. Y., has filed a certificate in the office of the Secretary of State changing its corporate name to New York State Electric Corporation.

## Annual Reports Show Gross Up 8.9 Per Cent

APPROACHING the normal yearly growth, gross revenue of power and light companies increased considerably less in 1927 than was the case during 1926. To date approximately 50 per cent of the companies, or, more properly, companies representing half the gross revenue of the industry, have issued their 1927 financial statements. The aggregate revenues of these companies has increased but 8.9 per cent over that reported by them in 1926, while 1926 figures show a 13.6 per cent growth over 1925 for the same companies.

These figures indicate that estimates published by Electrical World in the issue of Jan. 7 were substantially correct, in so far as this half of the industry is concerned. At that time it was estimated that gross revenue for the entire year would exceed that of 1926 by 8 per cent, reaching a total of $1,783,700,000. Companies which have already reported have a gross of $850,400,000, against $780,347,000 in 1926.

While substantially lower than the 1926 increase, and also that of 1925, an annual increase of 8 to 9 per cent approximates what would appear to be a normal or average annual increase. In 1926 the revenue of the industry increased 11.6 per cent; in 1925, 9.3 per cent, and in 1924, 7 per cent. Furthermore, the increase in power generated in 1927 over 1926 was 8.6 per cent.

## Metropolitan Edison Simplifies Structure

Fifteen issues of securities, totaling over $20,000,000, will be retired as part of a plan for simplification of the capital structure of the Metropolitan Edison Company. To accomplish the plan, as well as to pay for additions and betterments to the company's property, and other corporate purposes, an issue of $25,000,000 Metropolitan Edison Company first and refunding mortgage 4½ per cent bonds will soon be offered the investing public. The plan will also effect a substantial saving in interest charges. Carrying out of the program will reduce the number of issues of the company from seventeen to three. The funded debt, upon completion of the financing, will consist of the new issue of bonds, $7,650,000 first and refunding mortgage 5 per cent bonds (secured by the same mortgage as the new 4½s) and one divisional issue which is non-callable—$1,500,000 York Haven Water & Power Company 5 per cent bonds, due June 1, 1951. The issues being retired range in amounts from $6,252,600 down to $10,500. They consist of one Metropolitan Edison Company issue and fourteen issues of divisional bonds. The principal issues being retired are: $6,080,000 Metropolitan Edison Company 6 per cent bonds, $6,252,600 Pennsylvania Edison Company 5 per cent bonds, $3,250,000 Metropolitan Power Company 6 per cent bonds, $2,348,000 Metropolitan Electric Company 5 per cent bonds, $1,345,000 York Haven Water & Power Company 5 per cent bonds.

# Hartford Electric Light Company Reports Good Year

CONTINUED prosperity shared with its customers is reported in the annual message of President Samuel Ferguson of the Hartford (Conn.) Electric Light Company to stockholders covering the year 1927. The various rate reductions made at the beginning of the year caused a decrease in revenue in excess of $300,000, compared with what it would have been at last year's prices, but in the face of this gross revenues increased approximately $275,000 over 1926. Steady gains marked the year's business. Net earnings applicable to dividends and surplus enabled the company to declare a 40 per cent "customers' dividend" in the form of a discount on all October bills, which amounted to $185,000. Energy sold locally totaled 145,000,000 kw.-hr., against 137,000,000 kw.-hr. in 1926, while power sold other companies totaled 52,000,000 kw.-hr., against 55,000,000 kw.-hr. the year previous. The total power exchanged (with the Connecticut Valley group) was 23,000,000 kw.-hr., compared with 31,000,000 the year before. Sales of electrical energy totaled $5,330,400 (after customers' dividend reduction); expenses totaled $2,655,200, and net after taxes and retirement reserve was $1,711,900, compared with $1,662,900 for 1926. Total income for 1927 was $2,058,400, against $1,842,400 for 1926, and the balance carried to surplus was $336,400, against $384,100 for 1926. During the past three years "customers' dividends" have totaled $694,000.

President Ferguson states that during the year the company's investment in 10,000 shares of the New England Power Association was sold to the International Paper Company, the profits from the transaction being distributed to stockholders in the form of a payment of $1 per share. Regarding the deposit of stock, Mr. Ferguson states that all the directors and more than 35 per cent of the stockholders have complied with the company's recommendation that this be done, and suggests that others holding less than 200 shares should deposit all their stock and those holding larger amounts should deposit 200 shares to indicate their approval of the trust project, voting the balance themselves. The year was also a successful one for the Connecticut Power Company, which is largely owned by the Hartford company. The net earnings of the former increased $183,000, which is approximately 20 per cent greater than the earnings figure for the previous year.

## Energy Output in Mexico

Statistics on the output for the year 1926 of the leading electrical operating companies in Mexico, according to information recently received from the Mexican Department of Industry, Commerce and Labor, are given in the following table:

| Company | Kilowatt-Hours Generated |
|---|---|
| Cia. Mexicana de Lus y Fuerza Motriz, S. A. | 593,472,460 |
| Cia, Agricola y de Fuerza Eléctrica del Rio Conchas, S. A | 137,149,400 |
| Cia. de Tranvias Lus y Fuerza de Puebla | 86,400,440 |
| Cia. Eléctrica de Chapala | 80,175,522 |
| Michoacán Power Co | 53,715,788 |
| Cia. Eléctrica de Tampico, S. A | 38,789,590 |
| Guanajuato Power & Electric Co. | 36,617,91 |
| Cia. Tranvias Lus y Fuerza Monterrey | 26,085,98 |

# Business News and Market Conditions

## Bureau of Commerce Plans to Expand Facilities

Among the developments of the Bureau of Foreign and Domestic Commerce of the Department of Commerce made possible by added appropriations for the next fiscal year will be the establishment of six new district offices. These branches are to be located in Denver, Indianapolis, Birmingham, Pittsburgh, Milwaukee and one in the state of North Carolina. The Commerce Department already maintains 23 district offices and 34 co-operative offices in this country. The object of these offices is to render immediate service to nearby business men. The records of the department show that during the last fiscal year these offices performed more than 2,000,000 commercial services, an increase of approximately 600 per cent during the past five years During the same period statements from 405 concerns thus served indicate actual sales and savings approximating $10,000,000. These branch offices are equipped with foreign trade information regarding conditions abroad, sales openings, names of prospective buyers, packing suggestions, foreign tariffs, etc. They also have, or are developing, facilities for the promotion of domestic trade.

Another advance in the program of the Bureau of Foreign and Domestic Commerce during the next fiscal year will be preliminary work on three new regional surveys in the national commercial survey program which is planned ultimately to cover the entire United States. The "Commercial Survey of the Southeast" has already been completed and is available at the price of $1 per copy from the Superintendent of Documents, Government Printing Office, Washington, D C., or from any district office of the department. Field work in the New England survey has been completed and the report is now being prepared. Field work on the Pacific Southwest is well under way. Preliminary steps also have been taken for beginning field work in connection with four other regions.

## Primary Market for Carbon Brushes

An estimate of the primary market for carbon brushes, based on the 1925 census of manufactures compiled by the Department of Commerce, is given in the accompanying table. It is further estimated that the replacement market would be four times the primary market, considering the average life of the equipment listed as ten years and the average life of the carbon brush 2½ years.

## British Act on Wire and Cable Imports

A report of the standing committee of the Board of Trade to Parliament respecting the importation of insulated electric wires and cables has been published and is now available through the British Library of Information, 5 East 45th Street, New York, at 10 cents per copy. Primarily the report recommends that all imported wires and cables be properly identified as to their origin at the time of importation and also at the time of sale except such material as forms an integral part of a completed article.

## *Delinquent Electrical Accounts*

(Data Supplied by National Electrical Credit Association)

NUMBER OF ACCOUNTS REPORTED

| Division | January 1927 | January 1928 | Per Cent Increase or Decrease | Twelve Months 1926–7 | Twelve Months 1927–8 | Per Cent Increase or Decrease |

| Radio transmitting sets | 1,076 | 4 | 4,304 |
| Vacuum cleaners | 1,107,592 | 2 | 2,215,184 |
| Portable electric tools: | | | |
| Grinders and buffer | 10,000 | 2 | 20 000 |
| Drills | 70,000 | 2 | 140,000 |
| Carbon contacts | ......... | .. | 500,000 |
| Total | | | 21,108,200 |

# Market Conditions

SALES during March have shown a decidedly better trend than in the previous two months. Buying of small motors is prominent in the New England district. Several large orders for general schedule material also are reported. Much interest is noted in street lighting, and there is a steady demand for construction material. Industrial sales are active in the Eastern district and include turbo-generator units totaling $100,000. Substation equipment also was in demand by central-station companies.

Industrial buying continues active in the Southeast and steady business was reported. A street-lighting contract involving more than $1,000,000 was placed in St. Louis, and a normal volume of motor and transformer business was done with industrial concerns. The Middle West reports a general improvement in March with the trend continuing. On the Pacific Coast power company buying of equipment was the outstanding business, which included a 32,200-hp. waterwheel generating unit.

## *Metal Markets Quiet—Little Change in Prices*

Buying of the non-ferrous metals has been in limited volume in the domestic market. This lull was not unexpected after the activity of the first half of March. The large primary producers of copper continued to maintain their position at 14⅛ cents. Most of the business was done at lower prices ranging down to 14 cents, Connecticut. In spite of absence of active buying, lead prices continue firm at 6 cents, New York. Zinc is quotably a little stronger than a week ago, but sales are decidedly sparse.

NEW YORK METAL MARKET PRICES

|  | Mar. 14, 1928 Cents per Pound | Mar. 21, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 13.825 | 13 78¾ |
| Lead, Am. S. & R. price | 6 | 6 |
| Antimony............ | 10⅞ | 10½ |
| Nickel, ingot.......... | 35 | 35 |
| Zinc spots............ | 6 | 6.0½ |
| Tin, Straits.......... | 50⅛ | 53¾ |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper price March 21, 1928, 15⅞ cents.

## *Industrial Sales Active in Eastern District*

Industrial and utility business combine to bring increased activity in the Eastern market. Industrial interests have been developing a pronounced demand for prime movers of the turbo-generator type. A leading manufacturer of such equipment has secured an order from a company at Waterbury, Conn., for a 2,500-kw. unit to cost about $45,000, and a paper mill at Albany, N. Y., has purchased a similar unit to cost approximately $42,000. A chemical concern at Syracuse, N. Y., has contracted for several smaller turbo-generators for its local plant, totaling around $20,000. While the call for industrial motors has slackened, a resumption of demand is looked for at an early date. Copper mining companies have been prominent in the market recently for motors and kindred industrial apparatus and some sizable commitments are expected from this quarter in a short time. Baking interests, likewise, have been active, and among others the Continental Baking Company, New York, will likely be a large purchaser at an early date in connection with proposed plant expansion. Export account for industrial motors, particularly from South American mining companies, is showing improvement, with a primary call for units of heavier and larger sizes. Business in fractional-horsepower motors is fair, with a tendency to be a little spotty.

Substation and affiliated electrical equipment continues in good demand for central-station account. A utility company in the metropolitan district has placed an order for oil circuit breakers to an amount of about $175,000, while another central-station company has contracted for 2,000 distributing switches of the 7,500-volt type, totaling $14,000. A Buffalo utility company has purchased 200 switches of the 13,000-volt open type for rural line service from the same manufacturer. Circuit-breaker business has shown advancing proportions during the past month and there are excellent prospects for further sizable commitments. Line hardware has been recording some good sales and cable reels have been in demand by telephone companies. Marine electrical equipment is expected to enjoy a pronounced call within the next month or two; the government has several contemplated projects which are to be definitely settled within that time, while the city of New York will probably place orders for an electric-operated ferry-boat and fire-boat.

A feature of immediate construction work in the Eastern district is the expansion program of the Public Service Electric & Gas Company, Newark, N. J. Other construction projects include the following: The International Nickel Company, New York, will improve its properties at Port Colborne and Copper Cliff, Ontario, over a period of months to cost $12,000,000. The DuPont Cellophane Company, Buffalo, N. Y., plans an addition to its paper mill to cost about $200,000. Riverside, N. J., will improve its street-lighting system. The Amalgamated Silk Company, East Mauch Chunk, Pa., has authorized the electrification of its mill. The Pennsylvania Power & Light Company, Allentown, Pa., will build transmission lines in Roaring Creek at Catawissa Townships through two subsidiaries. The Stetson Rubber Company, Butler, Pa., will build a mill to cost $100,000. The Eastern Shore Public Service Company plans a transmission line to Millville, Ocean View, Bethany Beach and vicinity. The Love Point Light & Power Company, Love Point, Md., will build a transmission line to Queenstown. The Kelly-Springfield Tire Company, Cumberland, Md., plans a refrigerating plant for rubber conditioning to cost $100,000. The Board of District Commissioners, Washington, D. C., will receive bids until March 26 for lamp-posts and fittings for the electrical department. The Bureau of Supplies and Accounts, Washington, D. C., will receive bids until April 3 for insulated cable and wire for Eastern and Western yards (Schedule 8708).

## *Small Motor Buying Steadies New England Trade*

With the demand for heavy equipment and central-station supplies rather quiet, the encouraging activity in small motors in the New England district gives notable strength to the market. The sales volume of motors was slightly above normal and among the orders were recorded many units from 15 hp. to 600 hp. Small switch and control sales are fair. A number of large orders for general schedule material were placed, one for $6,500, another for $2,500, and consignments for general contractors' supplies totaling over $15,000. Much interest is reported in street lighting. Electric automatic pumping units are being considered for two localities in southeastern Massachusetts. Inquiries also are being received for a large number of special institutional lighting systems. Much encouragement is seen in the steady demand for new construction requirements.

Construction projects are as follows: The Boston Ice Company has bids open for a plant for Cambridge. The U. S. Gypsum Company has acquired a water frontage and will expend about $1,500,000 for a new plant at Boston. The Edison Illuminating Company, Boston, plans additions to the Edgar station consisting of extensions to the switch house and boiler plant. The Boston Rubber Shoe Company, Malden, Mass., has authorized electrification of its mills at Malden and Melrose, Mass.

## *Steady Business Reported in the Southeast*

An order for a complete 25,000-kva. substation was the most prominent one placed in the Southeast. The volume of business in meters and transformers is good, though the individual orders average about $1,500. One company purchased $5,700 worth of small power and distribution transformers and $1,200 worth of house type meters. A central-station company in south Georgia ordered regulators amounting to $4,000, while another company purchased $1,300 worth of sign equipment for four small installations. In connection with merchandising activities in the section, one power company recently sold 2,650 flat-irons in one town in a special campaign.

One of the small independent telephone companies in Georgia ordered 250 Southern white cedar poles.

A textile mill in North Carolina purchased a 1,000-kw. steam turbine and auxiliary equipment for its bleachery and a textile plant in Alabama ordered motors, transformers and switchboard equipment amounting to $17,000. A textile resale firm placed an order for motors totaling $8,000, and a Georgia ice plant ordered synchronous motors amounting to $2,000. Wiring materials totaling $30,000 are being ordered in connection with the Southern Railway shops at Macon, Ga., though this amount is being split in a number of small orders to local jobbers. Motor and transformer equipment on that job will cost in the neighborhood of $50,000 and orders on the same are pending. A municipally owned plant in one of the larger Florida towns is contemplating the purchase of a 1,500-kw. turbo-generator and a number of active negotiations for waterwheels and generators for the northern part of the section are under way. It is expected these latter propositions will be definitely closed during the coming week.

Construction projects are as follows: The Georgia Portland Cement Corporation, Saundersville, Ga., plans a mill to cost $1,000,000. Henderson, Ky., plans improvements in its power plant to cost $50,000. Paducah, Ky., has authorized surveys for a municipal power plant. The Carolina Gas & Electric Company will build a transmission line to Kinston, N. C. The North Carolina Public Service Company plans a transmission line to Mebane, N. C., and vicinity. The Powell Knitting Company, Spartanburg, S. C., plans a mill addition to cost $175,000. Danville, Va., plans improvements at its municipal power plant to cost $35,000.

## *Large Street Light Contract Placed in St. Louis*

Conditions in the St. Louis district have been fair. A normal volume of medium-sized motors and transformers for industrial concerns has been purchased. Contracts for street lighting to include the St. Louis down-town section were awarded at a total cost of considerably over $1,000,000. A railroad company signed a contract for five gas-electric cars, each with a 400-hp. single-unit power plant at a total cost for electrical equipment of about $70,000. Another railroad company also bought apparatus for converting four gasoline cars to gas-electric service at a total cost of $30,000.

Construction projects are as follows: The Southwestern Gas & Electric Company, Shreveport, La., plans a steam power plant to cost $1,000,000. Normandy, Mo., plans a vocational school to cost $125,000. The Commissioner of Indian Affairs, U. S. Indian Service, St. Louis, Mo., will receive bids until April 9 for electrical supplies (Schedule 22-a). The Bartholomew Battery & Supply Company, St. Louis, Mo., plans a new plant at Columbia, Mo., to cost $100,000. The Pillsbury Flour Mills Company, Minneapolis, Minn., plans a mill and elevator at Enid, Okla., to cost $1,000,000. The Southwestern Irrigated Cotton Growers' Association, El Paso, Tex., plans a cottonseed oil mill to cost $150,000. The Panhandle Power & Light Company plans construction of a transmission line to Claude, Tex. The Gates Chemical Company, Denver, Colo., plans a branch plant at Houston, Tex., to cost $200,000. The Fair Baking Company, San Antonio, Tex., will build a baking plant at Houston, Tex., to cost $175,000. Poplar Bluff, Mo., and Port Arthur and Forth Worth, Tex., plan ornamental lighting systems.

## *Improvement Noted in Middle West*

The consensus of opinion in the Middle West is that the first half of March showed an improvement and the last half will show the same trend. Reports emanating from the steel industry are encouraging and considerable construction work is under way. Utility companies are preparing for spring activities with a large amount of line extension planned. Orders placed covered eighteen 15,000-amp., two 2,000-amp. and four 4,000-amp., 15-kv. oil circuit breakers and disconnecting switches valued at $10,000, and "Mazda" lamps valued at $150,000. Jobbers' sales have accelerated somewhat.

Construction projects are as follows: The Miehle Printing Press & Manufacturing Company, Chicago, plans additions in plant to cost $500,000. The Buick Motor Car Company, Flint, Mich., plans a factory branch in Chicago, to cost $600,000. The Iowa Soap Company, Burlington, Iowa, will build a plant to cost $100,000. The Interstate Power Company, Dubuque, Iowa, plans a power plant at Harper's Ferry, Iowa. Hawarden, Iowa, has approved a municipal power plant to cost $40,000. The Iowa Railway & Light Company has applied for permission to build a hydro-electric plant on Cedar River, near Rochester, Iowa, to cost $2,000,000. The Consumers Power Company, Jackson, Mich., plans a hydro-electric plant in vicinity of Morley, Mich., to cost $5,000,000. Mora, Minn., contemplates a municipal power plant. Harvard, Neb., has authorized $40,000 for a municipal power plant. The Nebraska Electric Power Company plans an addition to its power plant at Ogallala, Neb. Cincinnati, Ohio, is having plans drawn for an automotive trade school, to cost $125,000. The Marshall Electric Company, Marshalltown, Iowa, plans a transmission line for service at Hartland, Dillon and Marietta. The Indiana General Service Company will build a transmission line from Fort Wayne to Marion, Muncie and Kokomo to operate at 132,000 volts. The Otter Tail Power Company plans reconstruction of transmission lines at Lisbon, Forman, Enderlin and Cogswell, N. D. Cedar Rapids, Iowa, and Whitefish Bay (Milwaukee, P. O.), Wis., will build ornamental lighting systems.

## *Power Companies Buy Equipment on Pacific Coast*

Power company business has bulked large on the Pacific Coast. The outstanding order was placed by Los Angeles City for its San Francisquito plant No. 1 and awarded to the Allis-Chalmers Manufacturing Company for a 32,200-hp. waterwheel, valued at $117,465, and a 25,000-kva. generator, valued at $165,200. The Westinghouse Electric & Manufacturing Company also was awarded a contract for oil circuit breakers to cost $29,294. Los Angeles also is in the market for 700,000 ft. of guy strand and $20,000 worth of poles. Eugene, Ore., is buying the initial material for its 18,000-hp. plant, to cost eventually $2,250,000, and is placing orders for a 9,000-hp. turbo-generator at a cost of $73,000, and six 2,500-kva. transformers for $34,660. Material for a 15-mile farmers' telephone line is wanted in the Ukiah district and for a 25-kilometer line by Mazatlan, Mexico. Railroad buying is rather quiet, industrial business is good and contractors' business, after a very poor February, is decidedly better.

Numerous motor orders placed by irrigation and orchard districts in eastern Washington and by lumber mills in the Puget Sound district, for replacements mainly, amounted to approximately $40,000 and included about 250 motors comprising from 300 hp. down for a "Kraft" paper mill in Pierce County. Tacoma also placed an order for its annual requirements of power and distribution transformers approximating $100,000. Specifications have been issued for motors and pumps for a cold storage plant in Wenatchee to cost $150,000. The British Columbia Electric Railway Company plans immediate construction of a 20,000-kw. distributing station in Victoria. The Pacific Telephone & Telegraph Company plans additional long-distance circuits connecting Seattle, Spokane and other cities at a cost to exceed $200,000.

Construction projects are as follows: The Mission Rock Company, Harry S. Scott, president, San Francisco, Calif., plans a cold storage and refrigerating plant to cost $200,000. The Truckee Utility District, Truckee, Calif., plans a distributing system to cost $20,000. The Hawley Pulp & Paper Company, Oregon City, Ore., plans electrification of its pulp mill. The Maple Creek Coal Company, Salt Lake City, Utah, plans extensions at its mines to cost $50,000. The Willapa Pulp & Paper Mills, Inc., South Bend, Wash., plans a pulp mill to cost $500,000. Monrovia, Modesto and San Leandro, Calif., plan installation of ornamental lighting systems. The Southern Sierras Power Company, Riverside, Calif., will build a steel tower transmission line from San Bernardino to Seal Beach, 58 miles, to cost $750,000. The Commonwealth Utilities Corporation, Denver, Colo., plans a 44,000-volt transmission line. The Pacific Power & Light Company plans transmission lines at Walla Walla, Wash., to cost $150,000, and a substation to cost $35,000.

# Activities of the Trade

## Railway & Industrial Gets Large Switch Order

A very large order for outdoor substation switching equipment recently has been placed by the Public Service Corporation of New Jersey with the Railway & Industrial Engineering Company of Greensburg, Pa. The order covers equipment for the West Orange, Roseland and Metuchen substations and includes the steel structures for two of the stations. The stations are for 154 kv. to 37 kv. service.

The major items that are to be furnished include 203 three-pole sets of "Hi-Pressure" contact switches, 102 motor-operating mechanisms, 1,250 interchangeable unit bus supports, 157 sets of single pole equipment and 450 tons of steel. The apparatus is similar to that furnished for the Public Service Corporation's Hudson station in 1927.

## Westinghouse Accident Due to Failure of Test Apparatus

The fatal accident which occurred on March 13 in the South Philadelphia works of the Westinghouse Electric & Manufacturing Company was not due to the explosion of a turbine, as stated in the newspapers, but to the failure of part of the temporary shop equipment for testing. The accident happened during the heater box run on the low-pressure spindle of a large turbine, stated H. T. Herr, vice-president of the company. During the shop tests of a large spindle, temporary equipment is required to permit the overspeed run in a special casing installed in the erecting shop. A coupling adapter plate, which is part of this equipment used only in shop tests, burst during the test and broke the coupling housing into fragments. This is the first accident resulting in serious injury since the opening of the South Philadelphia plant ten years ago.

## Woodward Governor Confers With Hydro Operators

As a means of giving operating men and engineers a more thorough knowledge of the basic theory and practical use of its equipment for the control of hydraulic turbines, the Woodward Governor Company recently held a four-day conference at Rockford, Ill., at which 58 operators from hydro-electric plants in the United States and Canada attended. This was the second annual conference which the Woodward company has arranged and both meetings have enabled the operators and engineers who design the equipment to study and discuss operating problems and conditions encountered in a large number of hydro-electric plants.

Methods by which highest efficiency and most accurate control could be obtained were demonstrated by actual operation of governors and the use of cut-away views of various types of machines. The final day of the conference was devoted to a general discussion of power plant operation and new types of machinery were suggested to be developed so that certain local plant conditions might be handled automatically. Both the governor company and the plant operators felt that the conference was a very definite benefit and plans have been made to hold such a meeting each year.

## American Pulverizer Moves Into New Plant

A new modern plant located at 1249 Macklind Avenue, St. Louis, is now the home of the American Pulverizer Company, manufacturer of the American rolling ring crushers. The company was formerly at Eighteenth and Austin Streets. The new plant has about 12,000 sq.ft. of floor space, is equipped with modern machinery, including an electric traveling crane, and is served with a private switch track connecting with the principal railroads. It is said that the company is now in a position to better than double its former production.

The Allis-Chalmers Manufacturing Company, Milwaukee, announces that E. D. Hill will represent the company at 42 Church Street, New Haven, Conn. The sales will be under the direction of A. F. Rolf, manager of the company's New York office at 50 Church Street.

The Black & Decker Manufacturing Company, Towson, Md., manufacturer of portable electric tools, announces the electric sander for smoothing surfaces.

The Wodack Electric Tool Corporation, 4627 West Huron Street, Chicago, announces the type B portable electric hand saw, which, in addition to vertical sawing, provides for bevel sawing at any angle up to 60 deg.

The National Carbon Company, Inc., Cleveland, announces the removal of the branch sales office and factory of the carbon sales division from 357 West 36th Street, New York City, to new and larger quarters at the company's plant at Fourteenth and Henderson Streets, Jersey City, N. J.

The Electric Vacuum Cleaner Company, Inc., Cleveland, announces that M. R. Sutherland and Harry C. Hahn have been appointed assistant sales managers. Mr. Sutherland assumes entire charge of organization matters and is responsible for the personnel of the field organization, while Mr. Hahn is responsible for trade relations and is essentially a contact and sales promotion man. He will have as his personal staff three regional representatives bearing the title of manager of trade relations. These men are Otto Best, Jr., with headquarters in New York City; Walter J. McCord, Jr., with headquarters at Cleveland, and G. L. Lord, with headquarters at Chicago. V. M. Cannon has been appointed assistant to the sales manager.

The Federal Electric Company, 8100 South State Street, Chicago, announces a new product, the "Fedelco" porcelain electric clothes washer.

The Delta-Star Electric Company, 2400 Block, Fulton Street, Chicago, announces the opening of a new Kansas City, Mo., office in charge of L. C. Hitzeroth, who has been transferred from the sales engineering division of the Chicago factory.

The Sundh Electric Company, Newark, N. J., manufacturer of control apparatus, announces the appointment of the Chas. L. Ward Company as its representative. The Ward company has offices at 701 Midland Building, 1229 Baltimore Avenue, Kansas City, Mo.; 734 Electric Building, Omaha, Neb., and Tulsa, Okla.

The Copperweld Steel Company, Glassport, Pa., announces that Paul Van Wagner has been appointed representative for the Pittsburgh district in charge of central-station and railroad sales, covering the distribution of Copperweld products in western Pennsylvania, western Virginia, western Maryland and the state of West Virginia.

The Electric Machinery Manufacturing Company, Minneapolis, manufacturer of synchronous motors and vertical alternators, announces the appointment of T. H. Hayes, 705 Traction Terminal Building, Indianapolis, Ind., as its sales representative for the Indianapolis territory.

The Krich Light & Electric Company, 558 Broad Street, Newark, N. J., jobber, announces a change in policy. The company has discontinued its general electric supply business and will hereafter confine its activities to the merchandising of electric specialties, such as vacuum cleaners, refrigerators, ventilating fans, sewing machines, radio, etc.

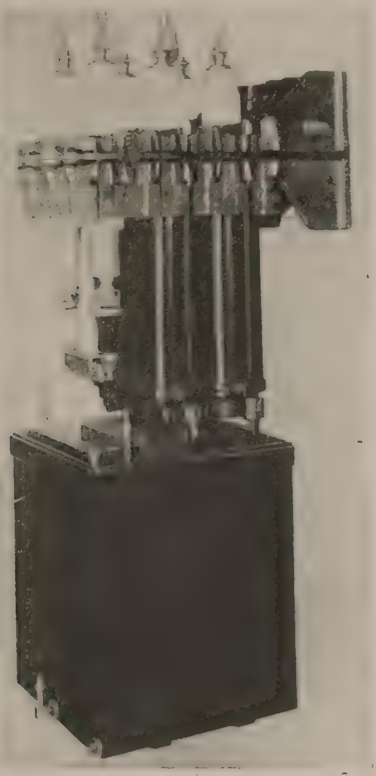
The National Fireproofing Company, Fulton Building, Pittsburgh, announces that Sidney F. Heckert was elected president at the annual meeting of the board of directors held on March 2.

Copeland Products, Inc., Detroit, announces that 35 new dealers have been added to the list of firms handling Copeland electric refrigerators, according to W. D. McElhinny, vice-president in charge of sales. The company recently demonstrated at Detroit its "Silica Gel" refrigeration unit which does not require a motor and compressor but is of the absorption type.

# New Equipment Available

## Compact High-Rating Oil Circuit Breaker

The type D-131 oil circuit breaker of relatively high interrupting capacity and comparatively small dimensions has been developed by the Condit Electrical Manufacturing Company, Boston. The line is built for 400, 600, 800 and 1,200 amp. at 15,000 volts, and 1,600 amp. at 7,500 volts, with an estimated interrupting capacity of 7,000 amp. at 15,000 volts. It is available in two, three and four-pole, single-throw, manually or electrically operated units. Features of the design include a double-tank construction cradle and spring suspension, a rugged frame and heavy arcing contacts.



*Double tank construction is used in this compact high-rating circuit breaker*

**Limit Switch for Control Circuits.**—A limit switch for controlling the limits of travel on such applications as motor-operated window- or door-opening apparatus, valves, etc., where magnetic control is used has been placed on the market by the General Electric Company. The switch is provided with two normally closed contacts, one for each extreme of travel. These contacts are operated by two cams, mounted on opposite faces of a molded gear. The two cams are adjustable with respect to each other and, as a further refinement, each contact has a micrometer screw which makes possible very close adjustment of the opening point for each contact after the general position of the cams has been set. The molded gear, with the two cams, is driven by means of a worm gear. The entire mechanism is inclosed in a cast-iron box with sheet-steel covers on the front and back. The contacts are both of silver.

## Heavy-Duty, Gang-Operated Disconnecting Switch

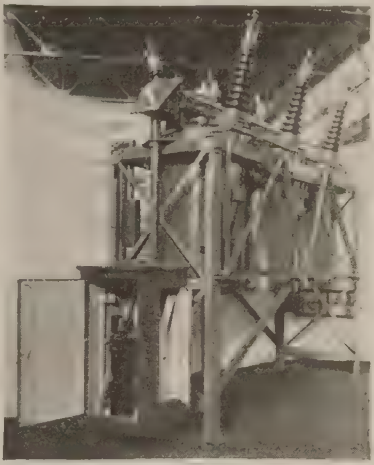
For heavy duty railway service and use on trunk feeders where the operating voltage is 11,000, the Delta-Star Electric Company, Chicago, has developed a gang-operated switch. It is equipped with corrosion and ice-breaking mechanism to insure easy and positive action at all times and is provided with ball bearings on the rotating bearings and swivel joints.

The full-floating, self-aligning contacts are fully covered by a copper sleet shield. The number of parts have been reduced to a minimum and all are said to be of exceptionally rugged construction. Although primarily designed for remote control by means of a motor mechanism, this switch can be furnished for remote manual control.

## High-Voltage Outdoor Oil Circuit Breakers

The design of a new line of outdoor oil circuit breakers has just been completed by the General Electric Company. The line is designated as the FHKO-139 type with interrupting capacities ranging from 350,000 kva. to 2,500,000 kva. The breakers are built to operate on voltages from 15,000 to 220,000. The breakers, from 15,000 to 88,000 volts inclusive, are mounted on a structural iron framework, while breakers of 110,000 volts to 220,000 volts are floor mounted. The breakers are built with "A," "B" and "C" interrupting capacity ratings, the "A" breaker having the wedge and finger plain break contacts, while the "B" and "C" ratings employ the explosion chamber. The breakers are constructed of boiler plate steel welded in place. The detailed design factors, electrical clearance, stroke, pressure type joints, sizes and weights for a given voltage and interrupting capacity were decided from tests both in the factory and in the field and in conformity with the company's experience in oil circuit breaker application.

Each single-pole unit has a flame-resisting lining of high dielectric strength, an oil gage, drain and fill valves and a separating chamber. The single-pole units are made of interchangeable design in so far as is possible. A semaphore is provided for the complete breaker to indicate the position of the breaker contacts; that is, whether open or closed. The drain valves are connected to a pipe at the bottom of the oil tanks in such a way as to permit complete drainage of the oil. The oil circuit breaker contacts are operated by a mechanism for providing a simple straight line motion. Each single-pole unit is equipped with buffer springs compressed in the closed position, a toggle effective in the closed position, a toggle stop, and dashpots to prevent rebound of the contacts. Each unit is provided with a balancing spring and the complete breaker has an opening spring such that the contacts are constrained to open throughout the complete stroke. The breakers may be manually operated, solenoid operated or motor operated. Trip free mechanisms are available for either solenoid or motor applications, while alternating-current operation is provided by means of the motor mechanism, which is of the centrifugal type. For breakers up to and including 37,000 volts the standard compound filled bushings are provided. For 50,000 volts and all higher voltages oil-filled bushings are provided. Breakers of 15,000-, 25,000- or 37,000-volt ratings are so designed that the American Institute of Electrical Engineers' minute test for the next higher voltage rating may be applied.



*Type FHKO-139, 73,000-volt solenoid-operated oil circuit breaker*

**Polyphase Switches.**—A line of polyphase switches built in sizes ranging from 60 amp. to 400 amp. with test connections and from 60 amp. to 600 amp. without test connections has been placed on the market by the Trumbull Electric Manufacturing Company, Plainville, Conn. These switches can be furnished with fuses sealable or accessible when the switch is in the "off" position. The switch is of slate base construction and the contacts are mounted on the top where they can be inspected in the "on" position.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued Feb. 28, 1928)

1,661,014. Short Circuiting and Brush Lifting Device for Dynamo Electric Machines; E. Schmock, Kiel, Germany. App. filed Dec. 16, 1925.

1,661,062. Electrical Water Heater; P. Ambory, Royal Oak, Mich. App. filed June 11, 1927.

1,661,102. Ended Cord and Method of Producing the Same; E. E. Waite, Framingham, Mass. App. filed Feb. 28, 1924.

1,661,103. Thermostatic Regulating Device for Heat-Producing Apparatus; A. O. Appelberg, Stockholm, Sweden. App. filed Nov. 3, 1925.

1,661,109. Transmitter for Electrical Control Systems of the Selective Type. Granted under the provisions of the act of March 3, 1883. R. C. Coupland, of the United States Army, Dayton, Ohio. App. filed May 13, 1926.

1,661,124. Terminal Clip; H. M. Koretzky; New York, N. Y. App. filed May 7, 1923.

1,661,127. Electrically-Controlled Combination Mechanism for Locks; R. H. Malicki, Chicago, Ill. App. filed April 18, 1925.

1,661,138. Incandescent Lamp Retainer and Mounting; R. M. Hill, Washington, D. C. App. filed May 28, 1923. Of the type used in motion picture apparatus.

(Issued March 6, 1928)

1,661,156. Production of Welded Wire Fabric and Apparatus Therefor; A. Armstrong, Tynemouth, England. App. filed Nov. 18, 1924.

1,661,166. Relay; T. S. Casner, Plainfield, N. J. App. filed April 23, 1925. Of high sensitivity adapted to be operated by relatively weak electrical impulses to open and close a local circuit of considerable magnitude.

1,661,170. Electric Driving System; J. Drukker, Amsterdam, Netherlands. App. filed Jan. 7, 1927. For phonographs.

1,661,173. Electric Furnace; C. B. Foley, Fort Wayne, Ind. App. filed March 23, 1922. Induction furnace of crucible type.

1,661,199. Container Cover; H. A. Selah, Erie, Pa. App. filed Dec. 26, 1924. Cover for conduit boxes.

1,661,208. Large Automatic Generating Plant; E. R. Witzel, Kohler, Wis. App. filed May 14, 1927.

1,661,222. Electric Heater; W. C. Hunt, Toronto, Ont., Can. App. filed March 12, 1927. Bowl reflecting type.

1,661,224. Primary Galvanic Battery; E. W. Jungner, Kneippbaden, Sweden. App. filed June 1, 1920.

1,661,258. Case for Fire Alarm Signaling Mechanism and the Like; F. B. Love, and B. H. Smith, Shelby, Ohio. App. filed Feb. 17, 1925.

1,661,268. Combined Transformer and Conduit Box Cover; A. E. Rittenhouse, Honeoye Falls, N. Y. App. filed May 1, 1926.

1,661,281. Electric Radiator; J. Bilan, Flint, Mich. App. filed June 13, 1927.

1,661,303. Electrode Rack; H. G. Price and B. K. Smith, Houston, Tex. App. filed Feb. 24, 1927.

1,661,331, 1,661,332. Apparatus for Winding Armatures; A. B. Gomory, Anderson, Ind. Apps. filed Sept. 26, 1924 and Feb. 3, 1923.

1,661,345. Alternating Current Magnet; C. H. Rippl, East Cleveland, Ohio. App. filed Feb. 26, 1927. As employed in contactors, circuit breakers and the like.

1,661,346, 1,661,347, 1,661,348, 1,661,349. Thermostatic Controlling Mechanism; C. B. Sawyer, Cleveland, Ohio. Apps. filed Nov. 17, 1922, April 4, 1923 and March 17, 1924. Such as depend for their operation upon the expansion or contraction of a fluid due to temperature changes.

1,661,352. Electric Switch; W. G. Young, Dayton, Ohio. App. filed April 30, 1925. Of the plunger type.

1,661,354. Anti-Freeze Container; W. W. Ayre, West Englewood, N. J. App. filed March 17, 1927.

1,661,373, 1,661,376. Conductor Clamp; E. F. Leighton, Anderson, Ind. Apps. filed March 15, and June 7, 1926.

1,661,434. Electric Switch and System; A. R. Locke, Chicago, Ill. App. filed Aug. 14, 1922. As applied to a multi-color lighting system such as used in theatre stages and auditoriums.

1,661,464. Heating Element Support; W. Campbell, Detroit, Mich. App. filed Aug. 13, 1923.

1,661,495. Swivel Connection; P. M. O'Neill, Fort Ethan Allen, Vt. App. filed Aug. 4, 1925.

1,661,497. Battery Terminal; G. D. Pate, Akron, Ohio. App. filed April 25, 1925. For storage battery.

1,661,553. Vacuum Cleaner Attachment; L. Baar, Los Angeles, Cal. App. filed March 19, 1927.

1,661,585. System of Rectification; F. Transom, Washington, D. C. App. filed April 2, 1925.

1,661,589. Anode Spacer; W. J. Winninghoff, East Orange, N. J. App. filed Aug. 27, 1924.

1,661,597. Water-Cooled Lamp; L. J. Buttolph, East Orange, N. J. App. filed Jan. 1, 1924. Apparatus for controlling radiant energy devices.

1,661,622. Brake System for Vehicles Running on Rails; H. Pieper, Brussels, Belgium. App. filed April 15, 1926.

1,661,625. Brake Device; H. Pieper, Brussels, Belgium. App. filed June 5, 1926.

1,661,637. Decoding Apparatus; A. J. Sorensen, Wilkinsburg, Pa. App. filed Nov. 18, 1926.

1,661,651. Electromagnetic Apparatus; P. N. Bossart, Swissvale, Pa. A direct-current electromagnet operated from a source of alternating current through asymmetric units.

1,661,683. Electric Heating System for Oil Pipe Lines; C. Setzefant, Modesto, Cal. App. filed Aug. 10, 1927.

1,661,689. Electric Candle Socket; T. A. Both, Stratford, Conn. App. filed July 26, 1921.

1,661,693. Electric Water Heater; J. H. Ewart, London, England. App. filed July 7, 1926.

1,661,694. Electric Resistance Furnace Adapted for Heating by Nitrogenization; A. Fry, Essen-on-Ruhr, Germany. App. filed Aug. 2, 1926.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

Purchase or agency is desired in Berlin, Germany (No. 30,122), for hot air driers and electromedical appliances.

A sole agency is desired in Caracas, Venezuela (No. 30,131), for household electrical appliances and small motors and dynamos.

An agency is desired in Alexandria, Egypt (No. 30,123), for portable reading lamps and light vase adapters and wiring devices.

Purchase or agency is desired in Basel, Switzerland (No. 30,168), for lighting fixtures, including flood lights and advertising appliances.

Purchase is desired in Vancouver, Canada (No. 30,176), of lighting fixtures and electric signs.

Purchase or agency is desired in Bucharest, Rumania (No. 30,167), for electric refrigerators.

An agency is desired in Munich, Germany (No. 30,126), for tools (electric hammers).

An agency is desired in Essen, Germany (No. 30,124), for portable electric tools.

An agency is desired in Frankfort, Germany (No. 30,125), for portable electric tools.

Two agencies are desired in Berlin, Germany (No. 30,128) and (No. 30,130), for portable electric tools.

An agency is desired in Fulda, Germany (No. 30,129), for portable electric tools.

Purchase is desired in Florence, Italy (No. 30,132), of electric vacuum cleaners.

An agency is desired in Mainz, Germany (No.30,127), for electric washing machines.

Marc-Henry Bornet, 8 Rue de Rive, Geneva, Switzerland, desires to get in touch with American manufacturers of electromedical apparatus, electrical household appliances and electric refrigeration units for the purchase of such material and to eventually arrange for an agency.

# New Trade Literature

STARTING SWITCHES AND PUSH BUTTON STATIONS.—Bulletins No. 209, No. 704, No. 709, No. 710, No. 720, No. 211 and No. 800 issued by the Allen-Bradley Company, Milwaukee, describe and illustrate respectively its direct-current across-the-line starting switch, alternating-current reversing switch, type J-1552, form B, across-the-line starting switch, type J-1552 form T across-the-line starting switch, type J-1552 form M across-the-line starting switch, type C-1201 direct-current automatic starter and its push button master stations.

DECORATIVE AND INDUSTRIAL LIGHTING.—A booklet issued by the Bryant Park Electric Lamp Company, 330 West 42nd Street, New York City, covers its colored lamps and their applications. The company is also distributing a bulletin covering the "Factrolite" unit, a modern industrial lighting source.

RAILWAY ELECTRIFICATION.—The General Electric Company, Schenectady, N. Y., is distributing bulletin GEA-828 and GEA-851, in which it describes the electrification of the Butte, Anaconda & Pacific railway and the electrification of the Mexican railway.

FLOODLIGHTS AND PROJECTORS.—The Crouse-Hinds Company, Syracuse, N. Y., is distributing bulletin No. 2109 describing the applications of floodlighting in buildings, monuments and signs of every sort. A number of illustrations show the various effects obtained. Bulletin No. 2106 issued by the company describes its types LCE, LCA, LDA and LDE floodlight projectors.

ELECTRIC HOISTS.—Bulletin No. 31 issued by the Chisholm-Moore Manufacturing Company, Cleveland, covers the C-M electric hoist for every purpose. It contains construction details and illustrations showing typical installations. Drawings and complete dimensions also are included.

BRAKES.—The Clark Controller Company, Cleveland, has published bulletin 102-C in which it describes the Clark "Three C" brakes. Illustrations are given showing the construction of the brakes and tables giving approximate dimensions, ratings, weights, etc., are included.

LIGHTNING ARRESTERS.—Booklet No. 248 issued by the Electric Service Supplies Company, Seventeenth and Cambria Streets, Philadelphia, entitled "Valve Characteristics of Lightning Arresters" is the fourth of a series covering the technical features of the crystal valve lightning arrester as they apply to modern lightning protection.

WINCHES.—The Silent Hoist Winch & Crane Company, 762 Henry Street, Brooklyn, N. Y., has issued bulletin No. 27 describing and illustrating the different types of Silent Hoist vertical and horizontal capstans, single and double drum winches, and self-contained units complete with electric motor and gasoline engine drive.

SWITCHBOARDS AND SWITCHING EQUIPMENT.—The General Electric Company, Schenectady, N. Y., has issued bulletin GEA-283A and GEA-582A, covering its alternating-current small plant and industrial switchboards with oil circuit breakers and its automatic switching equipment for synchronous motor-generators in lighting service.

PUMPS.—Bulletin No. 36 issued by the Beach-Russ Company, 50 Church Street, New York City, describes and illustrates its rotary pumps for various uses.

INDUSTRIAL LIGHTING.—"Points on Productive Lighting for Industry" is the title of a booklet published by the Benjamin Electric Manufacturing Company, 120 Sangamon Street, Chicago. It contains industrial lighting information, descriptions of various types of lighting equipment and their adaptation to meet specific requirements, a listing of recommended intensities for industrial uses and a chart for estimating lamp sizes for given areas.

PULVERIZING, GRINDING AND MIXING MACHINERY.—The Abbe Engineering Company, 30 Church Street, New York City, is distributing bulletin No. 23, describing and illustrating its pulverizing grinding and mixing machines.

ELECTRIC DRIVE FOR TANKERS.—The General Electric Company is distributing bulletin GEA-871, entitled "Diesel-Electric Drive for Tankers," in which it gives illustrations and data on ships equipped with the Diesel electric drive.

## *Unemployment Alarmists Are Belied by Facts*

FIGURES for unemployment in this country, freely bandied about, have attained a size that seems to have no basis other than that of political propaganda. The reliable available data show that the published unemployment figures for the country as a whole are in considerable part based on conditions of a seasonal or regional character. The energy consumption of about three thousand manufacturing plants throughout the nation, compiled by the ELECTRICAL WORLD, shows that the rate of production during February was about 16.2 per cent over December. This is slightly under the the rate reported for the same period of 1927, but considerably over the rate of increase reported for the same month in 1924, 1925 or 1926. In the electrical industry there is a distinct feeling of optimism as to the trend in business, particularly since the first of March.

To show further how far wrong current figures of unemployment are there may be cited the conditions in Baltimore, which recently was chosen by the Department of Commerce as a test city for determining actual employment conditions. Some opinions placed the number of unemployed in Baltimore at 70,000, and a careful estimate made by the Chamber of Commerce in conjunction with the various labor organizations set the figure at 60,000. An actual census made by the Department of Commerce gave the true figure as only 17,000, showing that the previous totals were hopelessly inaccurate. Unemployment figures are valuable to the executive as an aid in guiding his business. Unless they can be shown to be based on fact they should be cast aside as worthless.

* * * *

## *Indoor or Outdoor Domestic Metering*

AN ALMOST unanimous opinion and requirement on the part of electric light and power companies relegates the domestic meter to the dark inaccessibility of the far corners of the consumer's cellar. No hazard of life or limb is unknown in the multitudinous stretches between the back door and the entrance switch. Metermen must, in some cases, call many times before a reading can be obtained. Calibration tests are delayed and interminably postponed through failure to gain an entrance. Meters cannot be set or removed when desired. It is another item in the long roll of lost hours, labor and money. Is it necessary?

The large number of summer homes within its territory and a racial dislike on the part of local housewives to the tramping of muddy shoes across spotless and inviolate kitchen floors led a well-managed utility to consider the advisability of outdoor metering. Commercial and operating men agreed that it could be done if the increased cost of protective equipment were minimized. The result was the development of a zinc-aluminum case for back-porch or shed mounting, the inclosed meter being read through a glassed port. Service is brought directly from the pole to the meter. No fuses are used. Small insulated-handle switches are, however, utilized to break the circuit for test conditions. The distributing fuse box and service switch are installed in the cellar at a convenient point. Fuses for meter protection are considered economically unnecessary as a result of the comparison of figures for the cost of meter protection and of those for losses through burnouts. Meter accuracy is said to meet reasonable requirements. The plan is being approached slowly, but there are highly desirable features involved. It is estimated that, on a quantity-production basis, the metal cases will pay for themselves in less than a year when lost hours and income are evaluated in connection with installation charges.

* * * *

## *Super-Codes for Wiring and Lighting*

PROGRESS in the introduction of improved devices and methods has come largely through selling efforts by the manufacturers or by broadcasting the information through technical publications and conventions. This has always worked well and doubtless will continue so to do, but as time goes on cases are arising with increasing frequency where co-operative action by the industry is needed. One of the best examples of a co-operative effort of the industry directed to a specific purpose and accomplishing far-reaching results was the promotion of the convenience outlet idea in California in 1919-1922. Where the issues are more complex promotional effort is needed not merely to popularize the device or idea, but to prevent unfairness due to the large number of materials and methods involved. Of this class there is already one prominent example—the "red seal" plan—and more are apparently in the making.

An opportunity for co-operative effort exists in the illumination field. The Illuminating Engineering Society has drawn up codes for several classes of lighting, some of which have been made legal in various states. State laws can go no further, however, than to regulate matters pertaining to public health and safety. In illumination, as in many other things, there is quite a margin between minimum legal requirements and standards of good or desirable practice. But would it not be possible to draw up and get the general indorsement of the industry for certain super-codes of lighting of various classes which would in time come to be recognized as common standards of excellence? In other words, why not a "red seal" specification for the lighting of offices, another for industrial lighting, and so on?

Such specifications would naturally fall to the Illuminating Engineering Society. The promotion of the idea and practical working out of the plan would naturally be done through co-operative industry organizations, as in the case of "red seal" wiring. Such a movement would put a considerable check on the activities of numerous unscrupulous and ignorant salesmen working in the illumination field and would provide the customer and the conscientious illumination salesman with a standard by which to judge, or to have judged, the good and bad qualities of a lighting installation.

A start in this direction has already been made in Chicago under the name of the "Franklin specification," by which residence lighting fixtures for use in a refixturing campaign receive a Franklin specification certificate tag if passed by a technical committee. A Franklin specification for commercial lighting has also been promulgated. Local initiative in such things is desirable, for out of such local experiments come the most successful national movements.

* * * *

## *Attacking Operating Problems Instrumentally*

MEASUREMENT has been vital to electrical progress from its earliest days. Qualitative attacks upon involved problems and complex phenomena have been of little use to the engineer. Only as facilities for scaling quantities and values have been developed have control of energy in transmission and other links in the chain connecting sources of power and its utilizing equipment advanced toward mastery. This is an outstanding lesson of a paper by A. C. Monteith before the recent Midwest Power Conference on development in transmission apparatus tending to increase the reliability and efficiency of its service. The industry is surely entering an era of more accurate appraisal of transmission phenomena, and the next few years are bound to witness many striking advances in the collection, interpretation and interchange of vital information upon the many problems of successful energy transfer.

Instrumentation—using the term in a broad sense—lies back of modern studies of surges, characteristics of insulators, flashovers, relaying, checking apparatus design against operating performance and the control of frequency and voltage regulation. Recent developments in devices for the recording of extremely rapid phenomena on high-tension lines have opened a new door to the operating engineer, and these, combined with improvements and experiments in various auxiliary apparatus fields, promise much from the standpoints of reliability and efficiency. Money spent upon analyses now available through the skilled use and interpretation of improved forms of oscillographs and other means of reading subinstantaneous values will repay those who thus put their confidence in the latest methods. Field instrumentation has limitations of considerable magnitude, and the goal of the transmission engineer is still far off; for a vast amount of work must be done in the fields of apparatus design and analysis of operating situations before the anticipated standards of service will be attained in the face of lightning and other difficulties. But at least it has been made clear by Mr. Monteith and others that power men are "on their way" toward overcoming obstacles to service through the use of improved tools of engineering research.

## *Cutting Departmental Red Tape*

COMPLEX organizations created by the growth of power systems are doubtless essential to successful operation. It is possible, however, to carry organization refinements too far in the conduct of departmental affairs. Observation of such activities at close range indicates that on some properties a rigid application of account classifications in small matters may defeat its own ends. In a generating plant, for example, a fireman breaks a mirror in the boiler washroom. A replacement order starts on its way up the ladder of officialdom. It receives the successive approvals of the boiler-room foreman, chief engineer, assistant superintendent and superintendent of the production department, and then arrives on the purchasing agent's desk. Alas, poor Yorick! The mirror is pronounced, not steam-plant equipment, but furniture. Some other department officials' approval is required, seriatim, and after various delays for which no individual is to blame, the purchasing agent calls for competitive bids, and the machinery of office routine finally delivers a new mirror to the automobile department, which hauls it to the plant at a departmental charge of 25 cents per mile or less and delivers it in exchange for a receipt whose journeyings back to the "P.D." file need not be chronicled.

The moral of this and similar episodes is that there is a field for a limited petty cash or miscellaneous expense allowance under control of the ranking officer of the department needing minor supplies. Too often, we fear, high-salaried executives and their staffs in many companies find their conference proceedings encumbered by topics of petty-cash importance over which departments disagree, thanks to the elaborateness of the prevailing accounting system. Is not a larger sense of proportion needed in these cases and cannot trusted subordinates be allowed more latitude in reference to making minor purchases than at present exists? Why use sledgehammers to kill mosquitoes?

* * * *

## *Home-Modernizing Movement Deserves Hearty Support*

EVERY branch of the electrical industry should be keenly interested in the national movement to stimulate the modernizing of old homes that is right now being organized. The plan springs from three conditions:

1. There are some ten million homes in the country with obsolete equipment that modernizing would restore to full market values.
2. There is an enormous fund of money now in building and loan associations seeking investment.
3. The building trades are at present experiencing a slump with attendant unemployment.

This situation naturally suggests the possibility of a comprehensive national program for the remodeling and re-equipment of these homes to provide employment and investment and to recreate real-estate values through modernization. The scope of such a movement grips the imagination.

Some thirty-one industries and trades have interested themselves in the idea. They embrace lumber, paint, steel, cement, brick, gypsum, asphalt, insulation, plumbing, heating, bathroom and kitchen equipment, gas, electricity, real estate, and building and loan interests, with many representatives of special groups such as oak flooring, shingles, metal lath and the like. They plan to promote local modernizing campaigns in which civic beautification and other public interests will be invoked, and it would seem that the purposes involved would have a strong popular appeal.

The interest of the electrical industry is obvious. The inadequacy of house wiring is giving serious concern, because it blocks both the sale of appliances and the consumption of kilowatts. The manufacturers of wiring materials are suffering from overproduction. The contractors are facing a dwindling market in residence wiring. Jobbers and dealers are vitally affected. Electrical wiring and equipment will play a prominent part in the rehabilitation of these countless old homes so conspicuous in all cities. Therefore the electrical industry should support and help promote this movement, with a co-operating joint committee, in position to speak for all four of our national group associations. W. H. Hodge of the N.E.L.A. Commercial Section is chairman of a committee representing the electrical industry in this movement.

## *The Private-Plant Bugaboo*

MUCH ado is made about the use of private plants in industries. This is true even in those cases where the use of large amounts of process steam or other local conditions point very positively to the private plant as the economic solution when all cost and service values are studied. Any utility company should take the position that its duty is first to the industry it serves. If a proper analysis shows that any particular industry should make its own electricity, the utility should be first to advise such a course. This case will be the exception, and it will not mean a total loss to the utility, for there will be indirect benefits. Every employee of an industry must have electric service in his home; the community streets must be lighted; there are stores and other industries to be developed and thus a very large business for the utility is made possible. It may be far more profitable than a power business done at no profit.

* * * *

## *Overcapacity of Industry a Logical Condition*

OVERCAPACITY of industry is a much-abused term owing mainly to a lack of the proper appraisal of the trend of business. What constitutes an apparent overcapacity is mainly an economic growth based on the tendency to increased efficiency in production. A very important factor has been a decrease in the cost of production. This has been obtained through the addition of new machinery even to the extent of building new plants, and the industry is equipped with a capacity distinctly larger than is needed to meet current consumption—a logical condition because of expectations of business growth. The danger lies not in this temporary overcapacity but in the effort of each executive to get business in a factory designed to meet future demands by taking work from a competitive factory through the use of price levers. If overcapacity is balanced against the need that created it, if current markets are analyzed, if future growth is measured and if new markets are aggressively cultivated, overcapacity will cease to be a bugbear and become the marginal reserve necessary to any well-conducted enterprise.

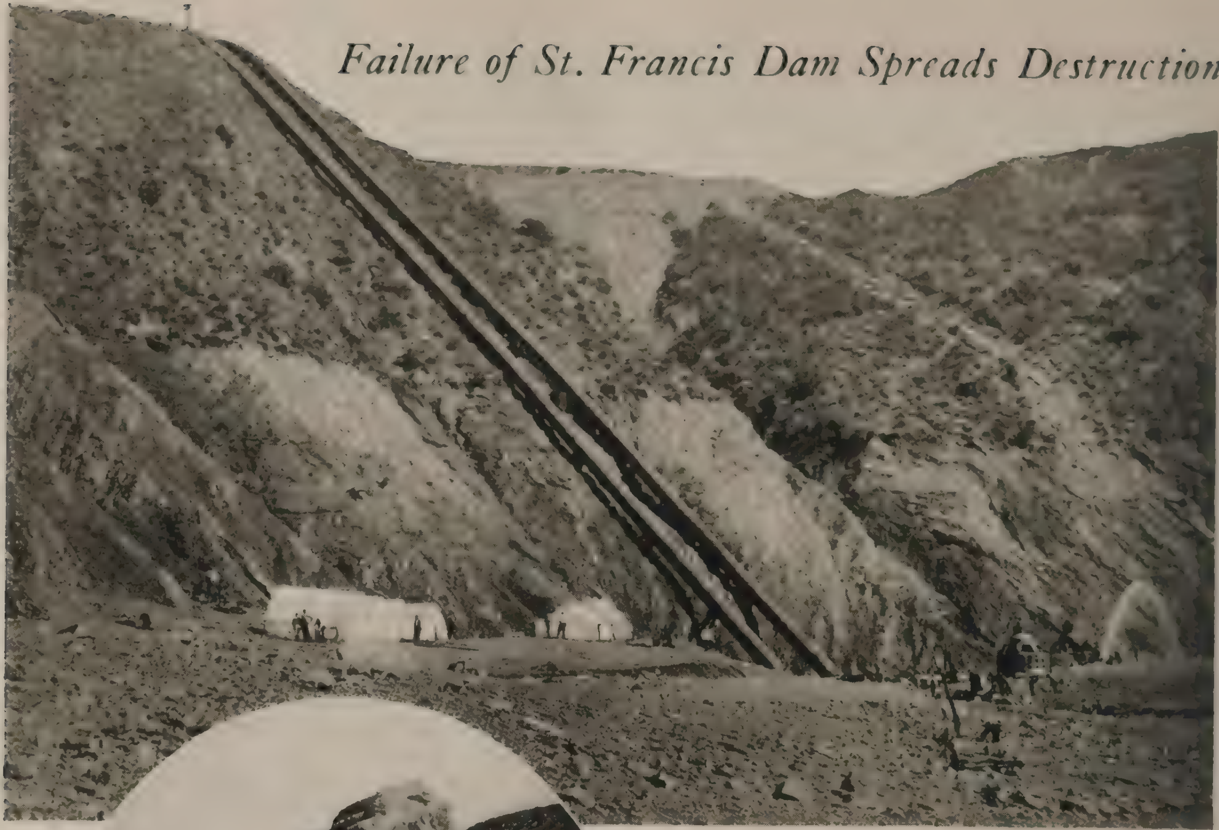
## *Reinvesting "Called Preferreds"*

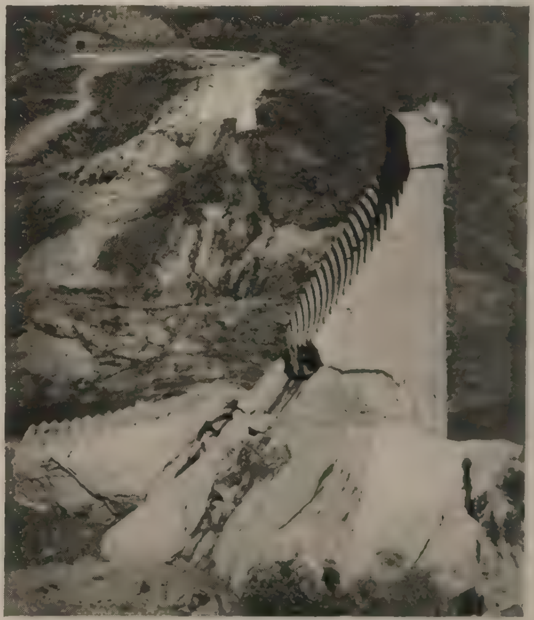
THE present downward trend in yields on high-grade public utility preferred stocks has a bearing on public relations that should not be overlooked by bankers and power company executives. Thousands upon thousands of customers and employees are facing the problem of reinvesting the proceeds of preferred stocks which have been redeemed at stated call prices, and the need of good advice and sound action is great. Probably most of these particular security owners are reaping a profit on the purchase price of their holdings. This is well, but when they approach the matter of yield on current reinvestment opportunities the picture changes. A definite reduction in income from preferred issues stares them in the face, and the course for the customer or employee owner to follow needs sympathetic consideration by the investment banker and by the utility man concerned in the distribution of company securities.

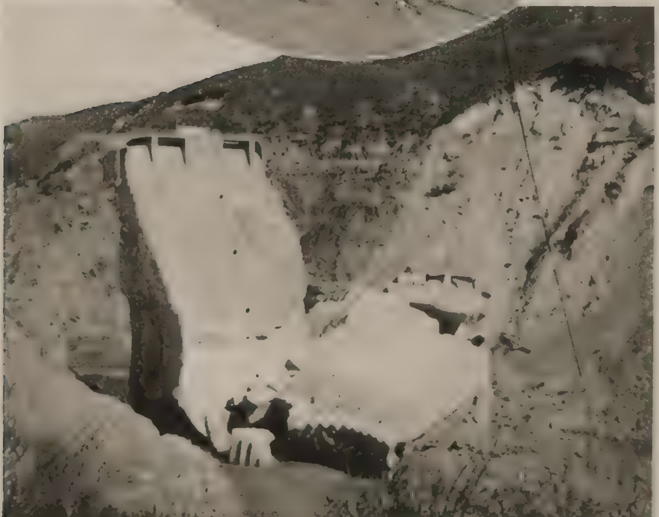
It is not enough to point out that the callable feature of a preferred stock formerly paying, say, 7 or 8 per cent was printed on the certificate and that the buyer who assumed that these rates would be continued for two or three decades after the close of the war has only himself to blame if he is upset over the termination of such returns. Nor is it sufficient to point out that countless security owners are receiving good profits on their transactions. The utility which has conducted vigorous customer-owner campaigns may well go beyond this purely defensive position and do what it can to render its preferred stockholders financial explanations which will enable them to understand the situation and in the long run to suffer as little as possible from a change due to the working out of the unchangeable law of supply and demand. This service may be given by the utility itself or by investment banking houses in close touch with the property, but where the operating or holding company has sought investment money from customers or employees, it now has a real opportunity to perform an important task in public relations by helping its investors to adjust themselves to the new conditions.

Various incentives to reinvest in the lower-rate preferreds are being offered holders of called stocks. Without cataloging these, it appears that in many cases the owner may share in the future prosperity of the company by participating in common-stock dividends above a stated figure, by converting the new preferred shares into common on favorable terms, or by receiving the right to buy common shares at established prices during a stated period, regardless of the market. These advantages appeal to some owners but not to others. An alternative is, of course, to invest the proceeds of the redeemed preferreds in utility common stock or bonds. The value of recurring rights to share in company growth through common-stock ownership increases the yield rate over a given period, and the high repute of common stocks of first-class companies as collateral for loans deserve to be emphasized. In many cases, indeed, the preferred stockholder need lose little or no income if he "switches" with intelligence, and opportunities still exist, indeed, for actual increase of total income through purchase of listed equities. For others the possibilities of bond appreciation should not be overlooked. Without embarking on a program of responsibility for advice concerning investments, utility companies face an opportunity to build warm business friendships with customer and employee owners during this transition period in security values.

# *Failure of St. Francis Dam Spreads Destruction*







NEAR midnight on March 12 the St. Francis Dam, in southern California, failed, releasing 38,000 acre-ft. of water, creating a flood estimated at between 500,000 and 900,000 sec.-ft., sweeping destruction to the valley below. Loss of life is estimated at 300 persons and property damage will amount to approximately $25,000,000.

# Single-Phase Condenser Motor

## Recent investigation and development of improved power factor motors indicate high attainable efficiency. Construction cost not a deterrent factor

By Prof. Benj. F. Bailey
*University of Michigan*

*The general characteristics of fractional-horsepower motors, the effect of design upon economy of operation, the application requirements of the several types and the desirability of motor improvements were discussed by Professor Bailey in the March 24 issue of* Electrical World, *page 597. The design, performance and operation of fractional-horsepower, single-phase condenser motors, offered as a corrective solution of the problem, are detailed in this second and final installment.*—Editor.

The fundamental idea of the condenser motor is old, but so far as I am able to find out no serious investigation of its possibilities has previously been made. The connections of a condenser motor are shown in Fig. 1. As in the split-phase motor, there are two windings, 90 electrical degrees from each other. The winding 2, however, would usually have approximately as much copper in it as the winding 1, although the number of turns in the two windings need not be the same. In most cases it would be advantageous to use more turns in winding 2 than in winding 1 and a correspondingly smaller size of wire, making the weight of the two windings approximately equal. Instead of a resistor we use a condenser $C$ connected in phase 2; this condenser remains permanently in circuit, although, as will be shown, it is usually advisable to use more capacitance when starting than when running.

The vector diagram of the motor when starting is shown in Fig. 2. The current in the winding $I_1$ lags by approximately the same angle as before, but by using a proper value of the capacitance the current in winding 2 may be made to lead. The total current is of course the vector sum of the two and may be made to be very nearly in phase with the voltage. The motor has therefore nearly 100 per cent power factor when starting. The angle $\alpha$ between $I_1$ and $I_2$ may be made nearly 90 deg. The starting torque for the same phase currents is therefore much greater and the sum of the currents is less, since they are added together at approximately 90-deg. phase difference.

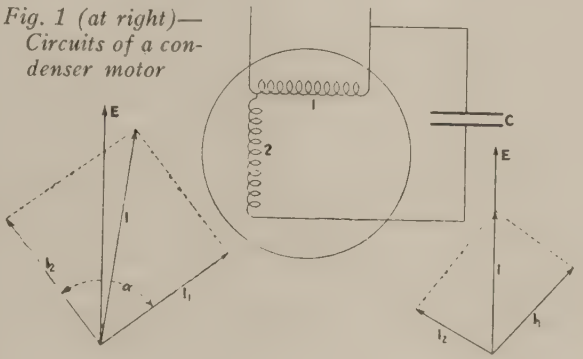
The starting torque of the motor, in fact, can be made as great as or greater than that of a polyphase motor, and since the currents add at nearly 90 deg. the line current will be less. The motor will therefore develop about the same torque as a polyphase motor with about 70 per cent as much current, giving a decidedly higher starting efficiency.

As in the case of the ordinary single-phase motor, the starting torque can, if necessary, be very much increased by reducing the number of turns in the winding 2. In general, however, the winding 2 may have more turns than the winding 1 and the motor will still develop ample starting torque. This enables us to use a smaller and cheaper condenser.

The vector diagram of this motor under full load and 100 per cent power factor is shown in Fig. 3. The current $I_1$ lags less than when the motor is starting and the current $I_2$ with the proper value of capacitance is nearly at right angles to $I_1$. The motor is therefore operating practically as a two-phase motor. It has the advantage over the latter, however, in that the currents $I_1$ and $I_2$ combine at such an angle that their resultant $I$, which is of course the line current, may be in phase with the line voltage $E$. The line current may of course be made to lead the line voltage if this is desirable.

If the capacitance of the condenser is so adjusted that the motor gives its best all-around performance under normal load it will be found that the starting torque with the same condenser will be quite low, usually in the neighborhood of 50 per cent. By using a condenser several times as large as this the starting torque can be increased to from 200 to 400 per cent. If the static torque of the load to be started is very low, but increases rapidly with the speed, a motor with a fixed condenser may be satisfactory. For example, a fan requires very little torque at the instant of starting and the necessary torque increases approximately as the square of the speed. A motor using a condenser adapted to give the best running conditions will be found to have a similar speed-torque curve (see Fig. 17), and hence may be used with advantage for such an application. Centrifugal pumps and grinders also have such speed-torque characteristics that they can probably be satisfactorily handled with a fixed condenser.

*Fig. 1 (at right)—Circuits of a condenser motor*



*Figs. 2 and 3—Vector diagram of condenser motor when starting and condenser motor vectors when at full load and 100 per cent power factor*

If, however, the motor must start a load such as a refrigerator compressor having large static friction it will be necessary to use a much greater value of the condenser at start and then reduce this to a suitable value for normal running. One method of doing this is shown in Fig. 4. Switch $S$, which may be operated either by a relay or by centrifugal force, is used to disconnect the condenser $C_2$ as soon as the motor has reached about two-thirds of normal running speed.

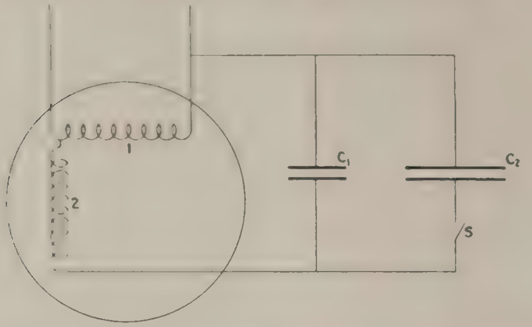


*Fig. 4—Method of varying capacitance after starting with high value*

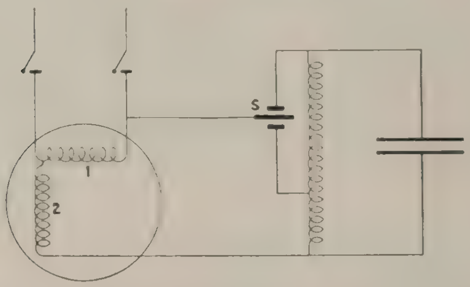

*Fig. 5—Method of varying capacitance by use of transformer*

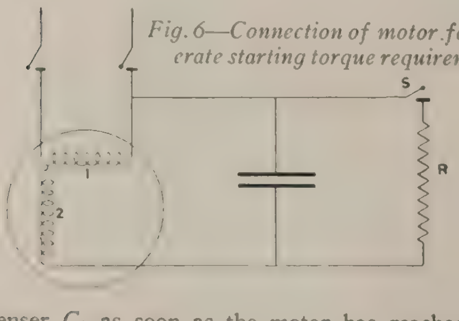

*Fig. 6—Connection of motor for moderate starting torque requirements*

Since the condenser $C_2$ may have several times the capacitance of the condenser $C_1$ its cost would be excessive if it were of the usual construction. This would be particularly true in the case of low-voltage motors. One method of reducing this cost is to use an electrolytic condenser in the place of $C_2$.

Electrolytic condensers have been known for a number of years. They consist essentially of two plates of aluminum immersed in a proper solution. Borax is frequently used for this purpose. The plates are first formed by passing direct current through them until a very thin film has been formed on the surface of the plates. Each plate then acts as an electric valve, allowing the current to flow in one direction only. Since the film is very thin such a condenser has an enormous electrostatic capacity in proportion to the size of the plates.

Electrolytic condensers have not been used to any great extent on account of their comparatively high loss. A paper condenser will have a power factor of approximately 0.5 per cent, whereas an electrolytic condenser will have a power factor of from 10 to 30 per cent. This large loss is of course objectionable in itself and in addition causes the cell gradually to lose its rectifying properties. It is therefore impracticable to use these condensers in continuous work where any large amount of power is involved.

For starting a condenser motor these disadvantages largely disappear. The increased loss results in only a small reduction of starting torque and the starting period is so short that the rise in temperature of the solution is negligible. Evaporation from a properly constructed electrolytic condenser can be made very slow, so that water need be added not oftener than once every two years. A rather crude home-made elctrolytic condenser has been operating in connection with a condenser motor driving the compressor of an electric refrigerator under my observation for twenty months. During this time it has had absolutely no attention. The level of the liquid due to evaporation has not lowered more than $\frac{1}{16}$ in. During one summer the outfit stood idle for about two months without any apparent depreciation.

Another connection designed to effect the same object is shown in Fig. 5. A condenser is connected to the motor through a variable ratio transformer. Preferably an auto-transformer is used, since this is somewhat cheaper and more efficient than the ordinary type of transformer.

At the instant of start the switch $S$ is closed on the lower contact of the transformer. The voltage applied to the condenser is increased and the current taken by the condenser is increased in the same ratio. The current flowing through the motor circuit is again increased by this same ratio due to transformer action. For normal running the switch closes on the upper contact and the effect of the condenser is correspondingly reduced. The upper tap on the auto-transformer, at least for higher voltage motors, might preferably be made at the extreme upper end. In normal running the transformer would therefore be inactive. Providing the necessary switches were not too complicated it might be entirely disconnected.

It is obvious that with this scheme a condenser of smaller capacitance may be used. On the other hand, it must not be forgotten that the thickness of the dielectric must be sufficient to stand the higher voltage. If we compare the condensers on the basis of their volt-ampere capacity this scheme effects no saving. It is, however, true that a condenser of a given volt-ampere capacity is less costly at say 440 volts than at 220. This saving is at least partially offset by the cost of the auto-transformer and the cost of the more complicated switch. There is, of course, a constant loss in the transformer and this reduces the running efficiency of the motor by about 2 to 4 per cent.

If only a moderate starting torque is necessary and if a comparatively large starting current is not objectionable the scheme shown in Fig. 6 may be used. Here a resistor is substituted for the condenser $C_2$. A motor operated in this manner will have better starting characteristics than a plain split-phase motor, but will, of course, not be so good in this respect as the condenser motor. The scheme is obviously cheap and might perhaps be satisfactory in connection with such applications as motors for oil burners or washing machine motors.

In Fig. 7 I have shown the characteristic curves of a condenser motor and those of the best motor that I have found of the ordinary repulsion-induction type. Both motors are of the same rating, namely, ¼ hp., 1,800 r.p.m., 60 cycles and 110 volts. The full load efficiency of the condenser motor is 75 per cent, that of the repulsion-induction motor 64 per cent. In other words, the customer's bill for the condenser motor would be 85 per cent of that with the best available repulsion-induction motor.

The power factor of the condenser motor at full load was 86 per cent, that of the other 66 per cent. By using a larger condenser the power factor of the condenser motor could be raised to 100 per cent.

The apparent efficiency of the condenser motor at full load is 64 per cent and that of the repulsion-induction motor 42 per cent. The corresponding full load currents are respectively 2.6 amp. and 4 amp.

In building the condenser motor a standard split-phase ¼-hp. motor was used. The stator winding was removed and replaced by a winding suitable for the condenser motor, otherwise the motor was unchanged. The total weight of the motor exclusive of condensers was 28 lb., whereas the repulsion-induction motor with which it was compared weighed 43 lb. I wish to make it clear that the improvement in characteristics was not obtained by using a large and expensive motor. It should also be emphasized that the repulsion-induction motor with which it is compared is one of the best, if not the best, on the market. For example, the full-load current of this motor was 4 amp. Other motors of the same rating which I have tested have taken full-load currents as large as 6.5 amp., giving an apparent efficiency of only 25.5 per cent. In Fig. 8 I have shown these same data graphically. In addition it will be noted that these two motors develop approximately the same locked torque. The locked current of the condenser motor is, however, 41 per cent greater than that of the repulsion-induction motor and its starting efficiency is correspondingly lower. The pull-out torques of the two motors are approximately the same.

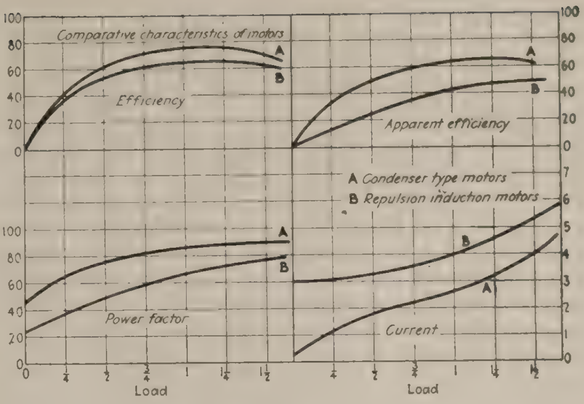

Fig. 7—Characteristic curves of condenser and repulsion-induction motors

In Fig. 9 I have shown a similar comparison between the same condenser motor and the best of a number of split-phase motors tested. The difference in efficiency, power factor, apparent efficiency and current is even more marked than before. In fact, it will be seen that the full-load current of the split-phase motor is nearly double that of the condenser motor. The locked torque of the split-phase motor is much less than that of the condenser motor and its locked current is much greater. The torque per ampere of the condenser motor is nearly four times as great as that of the split-phase motor, as indicated by the comparative starting efficiency. In pull-out torque the two are about the same.

### Comparison of Two-Phase and Condenser Motors

In order to get an accurate comparison between a polyphase motor and a condenser motor a standard ½-hp., 1,800-r.p.m., two-phase, 60-cycle, 220-volt motor was obtained. This motor was first carefully tested as a two-phase motor, with the results shown in Fig. 10. Without any change whatever the motor was then connected as a condenser motor, with the results shown in the same figure. It should be noted that the efficiency of the single-phase compares well with that of the two-phase. It is, however, slightly lower at light loads and at overloads due to the fact that the currents do not divide evenly between the two windings. This naturally results in greater $I^2R$ loss. At full load the efficiencies are prac-

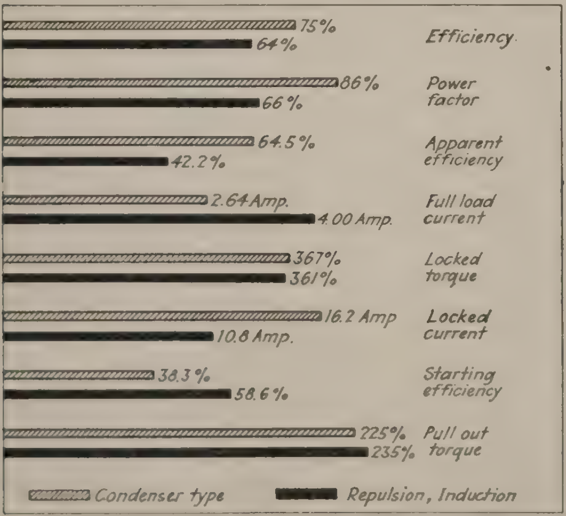

Fig. 8—Graphic comparison of condenser and repulsion-induction motors

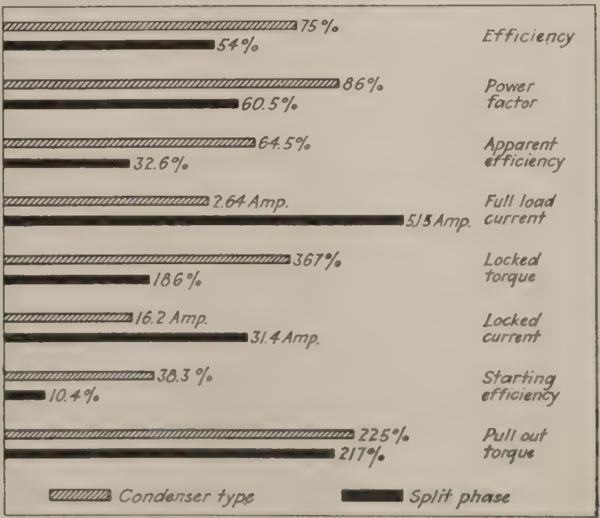

Fig. 9—Graphic comparison of condenser and split-phase motors

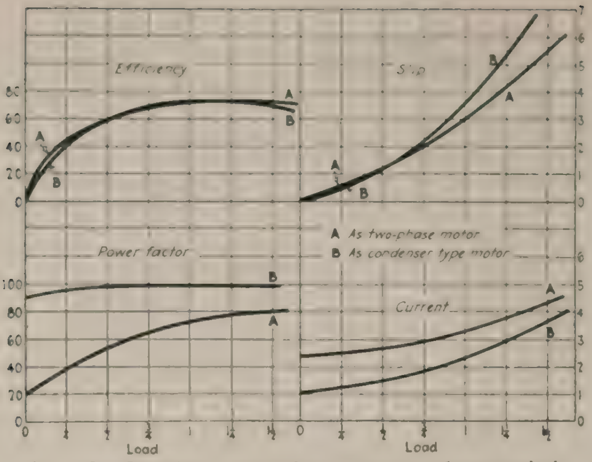

*Fig. 10—Standard two-phase motor characteristics compared to operation as a condenser motor*

tically the same. The power factor of the single-phase motor is much the better, being nearly 100 per cent throughout the usual working range. The slip in the two types of motor is practically the same. Since the efficiencies at full load are nearly the same, there is but little difference in heating at full load. The rating as a single-phase motor would be nearly as great as that of the two-phase motor.

The pull-out torque of the single-phase motor is, however, decidedly less. With the particular value of capacitance used it was 207 per cent, in comparison with 316 per cent in the case of the motor operated two phase. It was, however, amply high for all practical purposes and could have been made still higher by using somewhat greater capacitance.

The starting characteristics are shown in the following table:

| | Starting Characteristics | | | | Ratio Winding 1 to 1, |
|---|---|---|---|---|---|
| | Torque, Per Cent | Starting Current | Starting Watts | Starting Efficiency, Per Cent | Power Factor, Per Cent |
| Two-phase | 307 | 19.7 | 2,980 | 26.3 | 68.8 |
| Single-phase condenser motor | 362 | 17.72 | 3,880 | 34.5 | 99.5 |

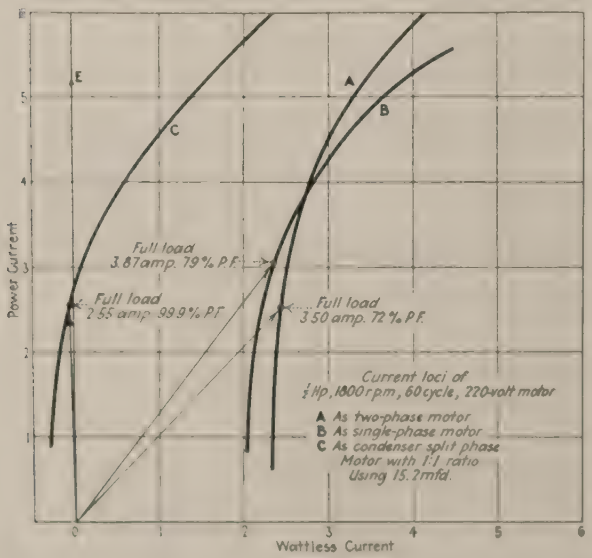

*Fig. 11—Curves taken on a two-phase motor with and without condenser*

It will be seen that the condenser motor has considerably more starting torque than the two-phase motor. If necessary, this could have been greatly increased by reducing the number of turns in the auxiliary winding. The starting current of the two-phase motor was 9.85 amp. per phase, or 19.7 amp. in all, whereas the single-phase motor required only 17.72 amp., or approximately 90 per cent as much. The single-phase motor necessarily took more power in starting, but its starting efficiency was much better. The power factor at start of the single-phase motor was 99.5 per cent and that of the two-phase motor 68.8 per cent. It is apparent that the starting characteristics of this type of motor are better even than those of a polyphase motor. Moreover, they can be varied to suit different conditions by changing the ratio of turns in the two windings and by changing the capacitance.

Fig. 11 will help to make clear the relative action of the two-phase, single-phase and condenser motors. These curves were all taken with a small two-phase motor. Curve *A* shows the locus of the current when the motor is operated two-phase. The angle between the vector marked *E* and any line drawn from the origin to the curve *A* indicates the lag of the current behind the voltage. The cosine of this angle is of course the power factor. In order to make the curves comparable the current plotted is that taken by both phases of the two-phase motor. It will be evident that the power factor will rise to a maximum at somewhat above full load and will then decrease for greater loads than this.

Similarly, curve *B* shows the locus of the current when operating on one of the two phases. It will be seen that in general the power factor of the single-phase motor is worse than that of the two-phase motor, particularly for heavy loads. By adding a condenser and connecting as shown in Fig. 1 we obtained the curve marked *C*. At light loads the current leads the voltage by a small angle. At full load it is nearly in phase with it, giving practically 100 per cent power factor, and for overloads the current lags, giving a power factor slightly lower than unity. The decided improvement in power factor will be evident from the diagram.

Fig. 12 is a more complete locus diagram of the different voltages and currents under various loads. The line voltage marked *E* is taken as axis of reference and of course remains constant. The curve marked "current in winding 1" shows the variation in circuit 1 as the load on the motor is changed. The current in circuit 2 remains nearly constant, as is shown by the short curve marked "current in winding 2." Obviously the power in this winding is also nearly constant.

The line current is obtained by adding vectorially the currents in winding 1 and winding 2. As is evident from the figure, the line current at all loads is nearly in phase with the voltage, giving practically 100 per cent power factor for all loads. As before, the line current is slightly leading for light loads and slightly lagging for heavy ones. The curve marked "voltage across winding 2" shows that this voltage does not vary much, but decreases somewhat as the load is increased.

In Fig. 12 the two windings had the same number of turns. Each winding, however, consisted of two circuits connected in parallel. By connecting the two circuits of winding 2 in series the ratio of turns was changed from 1 to 1 to 2 to 1. The capacitance of the condenser used was reduced from 15.2 mfd. to 6.75 mfd. Since it was subjected to a higher voltage, however, the volt-amperes in the condenser remained practically the same. (Fig. 13.)

Fig. 13—Locus diagram of condenser motor with 2 to 1 ratio of turns

As before, the power and current in the condenser circuit remain practically constant. Obviously this current must be at right angles to the condenser voltage represented by the line drawn from the end of the voltage vector to any point on the curve marked "voltage across circuit 2." Since the voltage across circuit 2 is nearly twice as great as before, the condenser voltage is more nearly at right angles to the line voltage. The current is therefore more nearly in phase with the line voltage and as a result forces the current in circuit 1 also to be nearly in phase with the line voltage. As before, the vector sum of these two currents gives the line current. This leads slightly at light loads and lags somewhat at heavy loads, giving 100 per cent power factor at approximately full load. The use of a high ratio enables us to use a condenser of small capacitance, and it is therefore somewhat cheaper, although the volt-ampere capacity is approximately the same. It will be evident that the currents in the two windings are far from being 90 deg. from one another and therefore are not in the best relation to give high efficiency and large overload capacity to the motor.

### Change of Performance with Capacitance

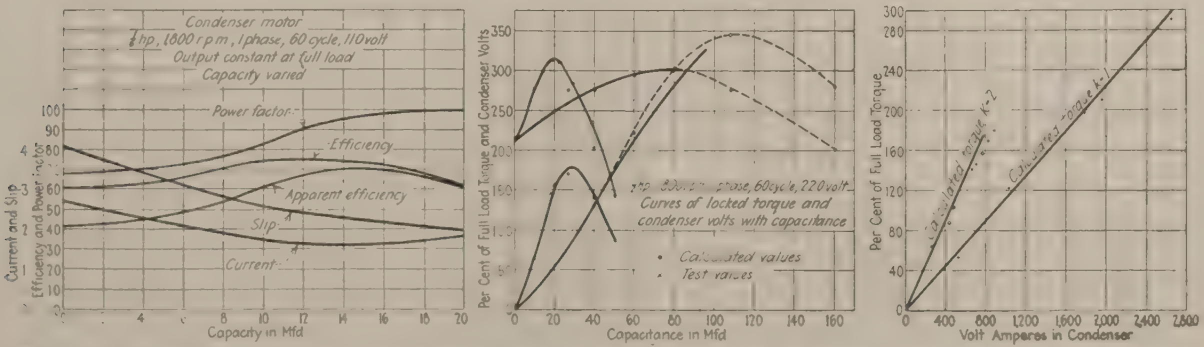
In Fig. 14 I have shown what happens in a small condenser motor operating with different values of capacitance. The output of the motor was held constant at ¼ hp. and the capacitance varied from zero to 20 mfd.

With zero capacitance the motor, of course, operated like the usual split-phase or repulsion-induction motor. Its efficiency and power factor were both low and the current and slip high. As the capacitance was increased the efficiency improved, reaching its maximum at about 12 mfd. Beyond this point it again decreased. The point of best efficiency is reached when the currents in the two windings are approximately proportional to the cross-section of the wires used. This results in minimum copper loss and high efficiency.

The highest power factor, namely, 100 per cent, was attained with 18 mfd. The efficiency, however, was decidedly lower. The highest value of apparent efficiency and the lowest value of current are obtained with approximately 14.5 mfd. The slip continually decreases as the capacitance is increased. The best all-around performance of this motor is obtained with approximately 12 mfd., although its characteristics are nearly as good with only 10 mfd.

In Fig. 15 I have shown how the starting torque varies with the capacitance. These tests were made on the same motor previously used in obtaining the curves of Figs. 12 and 13. When operated with a ratio of 1 to 1 the torque rose to a maximum of nearly 350 per cent with 110 mfd. The torque can be computed by fairly simple methods and both the observed and calculated values are shown on the curve.

The smaller curve at the left shows the starting performance of the motor when connected with a ratio of 2 to 1. The maximum torque is half as great as before and is obtained with only one-quarter as much capacitance. The microfarads required per pound foot are



Figs. 14, 15 and 16—Effect of variable capacitance on performance and on starting torque and relation between volt-amperes and torque of condenser motor—points calculated, curves observed therefore only half as great. In designing one of these motors, so far as starting torque is concerned, the cheapest construction will be obtained by using as high a ratio of turns as will allow us to obtain the necessary starting torque. If necessary, the torque could be made exceedingly great by using a very low ratio, but only with a very large and expensive condenser. The two other curves starting from 220 volts show the voltage across the condenser with different values of capacitance. The peaks of these two curves should theoretically reach the same maximum value. The differences observed are probably due to the difficulty of keeping the temperature of the motor constant with the heavy starting currents used.

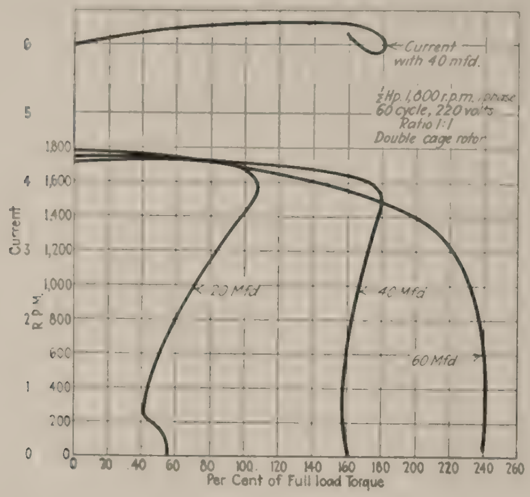


*Fig. 17—Speed-torque curves of a condenser motor*

In Fig. 16 I have plotted the volt-amperes in the condenser and the per cent of full-load torque. The volt-amperes are of course obtained by multiplying the current in the condenser by the voltage at its terminals and may be obtained from the preceding curves by a simple calculation. It can be shown theoretically that these curves should be straight lines and this is confirmed by the tests. As before, with the ratio of 2 to 1, only half as much condenser capacity per pound foot is required as with the ratio of 1 to 1.

The curves of Figs. 15 and 16 referred to the locked torque of the motor. This is, of course, important, but it by no means tells the whole story of the starting ability of a motor. A frequent complaint in connection with the repulsion-induction motor is that while it will start the load it will not pull it up to speed. In Fig. 17 I have plotted the complete speed-torque curves of this same motor. It will be seen that the torque remains nearly constant from standstill until the motor has attained normal running speed. However, with a small value of capacitance there is a decided increase of torque as the motor speeds up. This, as was previously pointed out, makes it possible to start certain kinds of loads even though the initial torque is rather small.

Fig. 18 will serve to show the possibilities of the condenser motor. The motor in question was rated at only ¼ hp. In spite of the small size a full-load efficiency of 73 per cent and maximum efficiency of 75 per cent were attained with a full load power factor of 86 per cent. The motor developed a starting torque of 320 per cent. This large torque was not obtained by the use of a high-resistance rotor, as will be evident from the fact that the slip at full load is only 2.5 per cent. Such performance is entirely beyond the possibility of the split-phase or repulsion-induction motor, or, to put the matter a little differently, no matter how good the performance of a split-phase motor might be, it could be very much improved by rewinding and operating it as a condenser motor.

The above facts serve to show that it is now possible to build single-phase motors nearly equal in efficiency to two-phase motors and far superior in power factor. Compared with split-phase motors, the characteristics of the condenser motor are superior in every respect. They are better than those of the repulsion-induction in every respect except in locked torque per ampere. The pull-in torque, however, is much better than that of the repulsion-induction motor, so that, everything considered, I have no hesitancy in saying that the starting performance also is superior.

### Cost the Handicap

At the present time, due to the high cost of condensers, a condenser motor costs somewhat more than the repulsion-induction type and decidedly more than the split-phase motor. It is, of course, too early to predict the difference in price with any real accuracy, but it is apparent that this difference need not exceed $10 in the case of a ½-hp. motor, and if such motors are produced in large quantities the difference will undoubtedly be less. The motor itself will cost about the same as the split-phase motor and decidedly less than the repulsion-induction motor. The condenser is the costly element, but if these are produced in quantities the price can undoubtedly be materially reduced.

Even though this difference should be as much as $10, it is clear that the central station could save more than this if the better motor were used. Unfortunately, there is no obvious way in which the central station can directly finance the introduction of these motors.

The customer would profit by reason of reduced bills. This reduction would amount to from 50 cents to $1 per month and would easily pay for the increased cost of the motor in a short time. The fact that the motor is quieter than other types, due to the fact that it operates practically as a two-phase motor, is also of tremendous importance. It may well be that the reduced noise will be the advantage which will result in the introduction of these motors, since the question of noise, particularly in modern apartment houses, where hundreds of refrigerators are running at the same time, is assuming very great importance.

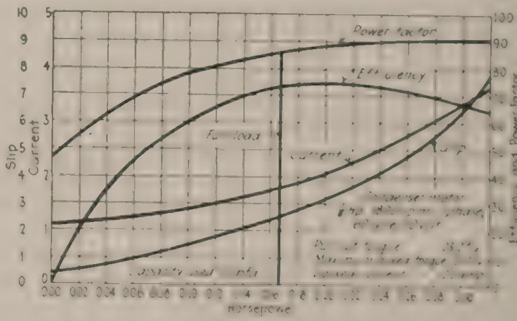

*Fig. 18—-Performance possibilities of condenser motor*

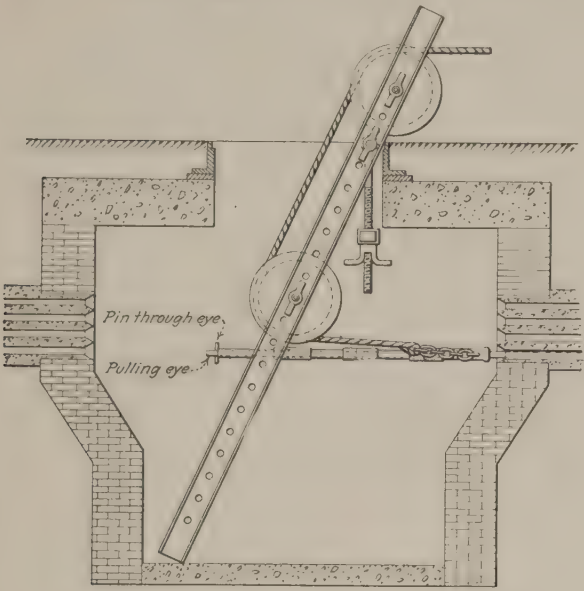
# Slack-Pulling Device Protects Cable Sections

By N. E. Buck

*Superintendent Underground Cable Work*
*Commonwealth Edison Company, Chicago, Ill.*

After a length of underground cable has been pulled through the duct and approximately to the center of the manhole, or in line with the pulling equipment, it then becomes necessary to pull additional slack to provide a sufficient length of cable to train around the manhole wall. In the past it has been the practice to pull this slack with various kinds of hitches, including woven wire grips. However, if the pull is long, or if the cable is "soft," that is, contains a large percentage of insulation to copper and lead, the lead sheath may be damaged or even broken by such hitches.



*Cable slack pulled without straining materials*

The Commonwealth Edison Company utilizes a slack-pulling tackle by means of which the necessary amount of slack may be pulled without injury to the cable. The cable is pulled through the duct by means of a pulling eye soldered to the copper and lead, and this eye is left in place until after the slack has been pulled. The device consists of a number of sections of straight steel tubing about 1 ft. long on one end of each of which is welded a steel collar. When the sections are assembled the end of one section enters the collar on the adjacent section, and the several sections of cable together form a very rigid tube. The sections are slipped on the end of the cable in sufficient number to build up a tube equal in length to the slack desired. The section at the cable end is prevented from coming off by means of a heavy pin passed through the pulling eye, and the last section, the one nearest to the duct, is equipped with a sling, to which the cable-pulling rope is attached. The slack is thus pulled from the end of the cable, the sheath and insulation are subjected to no undue strain and usually the total slack can be obtained in one pull.

# Portable Automatic Substation Aids in Maintaining Service

An AUTOMATIC 1,000-kw. substation equipped with rotary converter, transformer, oil circuit breaker and feeder equipment has been mounted on a railway car and placed in service by the British Columbia Electric Railway. The portable substation is designed for use in emergencies or where there is a sudden increase in demand.

The equipment includes a 1,000-kw., 600-volt d.c., six-phase, 60-cycle rotary converter, a 1,100-kva., three-phase, self-cooled transformer, a motor-operated high-tension oil circuit breaker, a.c. and d.c. lightning arresters, gang-operated air-break switches and two service-restoring 1,100-amp. direct-current feeder equipments.

The apparatus is mounted on an all-steel car with converter and switchboard inclosed. The transformer, oil circuit breaker and all other high-tension apparatus of the outdoor type are mounted on the uncovered portion of the car.

The station is fully automatic, being started and stopped by load demand. Protection against low voltage, phase reversal, a.c. and d.c. overload, overheating of windings and bearings, reverse polarity, overspeed, phase unbalance, loss of field, etc., is provided. Connection to either a 11,500- or 34,500-volt line may be made. Feeders are automatic, reclosing upon condition of normal resistance in the feeder. Excess direct-current load actuates contacts of load-limiting resistances and shifts the load to other stations. Thermal relay action permits automatic restarting when high temperature conditions have been relieved by radiation.

The car is the joint product of the Ottawa Car Company and the Canadian Westinghouse Company, Ltd.

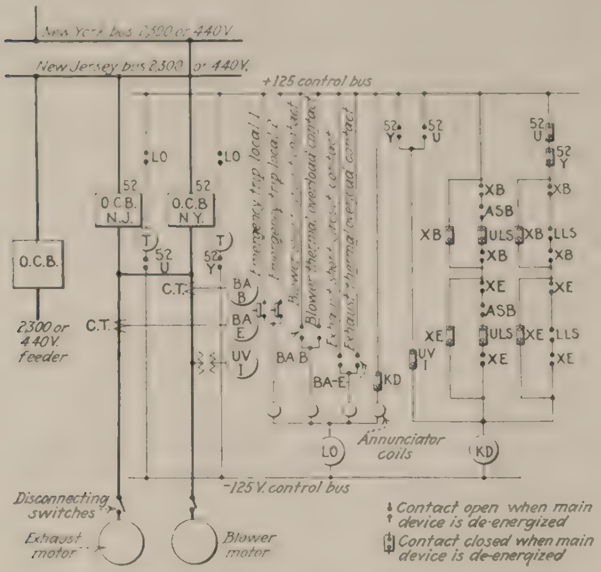
# Complete Relay Protection for Fan Motors

By J. P. Maxwell
*Switchboard Engineer*
*Westinghouse Electric & Manufacturing Company*

Motors driving the blower and exhaust fans used in the Holland vehicular tunnel (New York-New Jersey) are provided with full protection against incorrect operation and emergencies. Large blowers and exhaust fans operate from 2,300-volt service, small ones from 440-volt buses.



*Protective wiring plan for fan motors*

ASB—Auxiliary speed relay for blower.
ASE—Auxiliary speed relay for exhaust.
LO—Multicontact lockout relay.
KD—Undervoltage time-delay relay.
BA—Short-circuit and thermal overload relay.
CT—Current transformer.
LLS—Lower limit switch on damper, closes when damper is closed.
T—Trip coil.
ULS—Upper limit switch on damper, closed when damper is open.
XB—Auxiliary switch on blower motor disconnecting switch.
XE—Auxiliary switch on exhaust motor disconnecting switch.
52—Oil circuit breaker.

Whether the switchboard or local control is employed, the protective features for the motors are the same. Each motor circuit has a thermal overload relay with a short-circuit element. Besides protecting the motor from excessive temperature rise due to overload, the relay will operate if a short circuit occurs. To protect the motors during the starting and stopping period against failure of the speed-control devices and against the accidental closing of the dampers when the motors are running, a long time delay undervoltage relay has been supplied. This relay, known as Westinghouse type "KD," is continuously energized as shown on the diagram through one of the following circuits:

Through the auxiliary switch of either closed circuit breaker and a contact of a de-energized undervoltage relay; through the contacts on the auxiliary switch on the blower motor disconnecting switches (disconnecting switches being open); through the auxiliary switch on the blower motor disconnecting switches (disconnecting switch being closed); through the interlock on the auxiliary speed delay for the blower; through the upper limit switch on the damper when damper is closed, and similar circuits on the exhaust motor; through a circuit made by the contacts of both oil circuit breakers that are in the open position; through an auxiliary switch on both blower and exhaust motor disconnecting switches (switches being closed), and through the lower limit switch on the damper when the damper is closed.

All the protective relays used with the motors operate a multi-contact lockout relay. This lockout relay has several contacts, one of which changes the brilliancy of the white lamp on the control board from dim to bright, indicating an automatic operation, another of which energizes a bell alarm relay. These lockout relays are of the hand-reset type, and when once energized by the protective relay the operator must reset them before the oil circuit breaker can be reclosed. The protective relays, in addition to operating the lockout relay, also pick up an annunciator relay, Westinghouse type "JL," thus indicating which protective relay tripped out the motor breaker.

# Switch-Stick Housing

Outdoor substations that include stick-operated disconnecting switches present a small problem on some properties. Shall a stick be kept at the station, perhaps hung up somewhere and exposed to the weather? Or shall it be the duty of the man who comes to operate the disconnecting switches to bring a stick along with him? Both of these answers are open to obvious criticism. On the system of the Kansas City Power & Light Company this difficulty is met by use of the device here illustrated. It consists merely of a piece of 2½-in. galvanized conduit capped at the top end and with the slot as shown in the accompanying illustration in the other end. The stick is pushed into the pipe, handle first, and the hook on the head is turned into the slot, thus preventing the stick from sliding out of the pipe. The pipe is mounted at an angle of 45 deg. wherever convenient on the station structure. The turned down ⅜-in. ell near the top of the pipe is to permit air circulation along the length of the stick and thus to prevent moisture condensation on it.

# Coal-Handling System of Buffalo Utility

By F. S. Helfter
*Junior Engineer Buffalo General Electric Company, Buffalo, N. Y.*

UP TO the present time at the Charles R. Huntley station coal to and from storage has been handled by grab buckets operated from locomotive cranes on trestles and tracks in the coal storage yard. With the installation of additional station capacity, which included coal pulverizing equipment, this system of coal handling has been found both inadequate and impractical. In the new arrangement two cars, after previously being weighed on a track scale, are dumped simultaneously into four concrete hoppers which are built into the existing trestle. A shaking feeder, having a rated capacity of 75 tons per hour, located at the mouth of each hopper feeds the coal onto a horizontal belt, *A*, which in turn discharges onto an inclined belt, *B*, delivering normally to a 12-ft. x 19-ft. Bradford breaker. However, depending upon the position of a flopper gate, the coal falling from the head end of this belt may be deflected in whole or in part through a chute directly onto another belt, *C*, delivering the uncrushed coal to the initial pile of the drag scraper system for yard storage.

The coal passing through the breaker falls on a short feeding belt that discharges through a flopper gate either onto a belt, *E*, delivering to the house, or onto the inclined belt, *C*, to the initial storage pile for the drag scraper, or if desired both ways at the same time. Normally, only run-of-mine coal is stored, but the equipment permits of similarly handling the crushed coal.

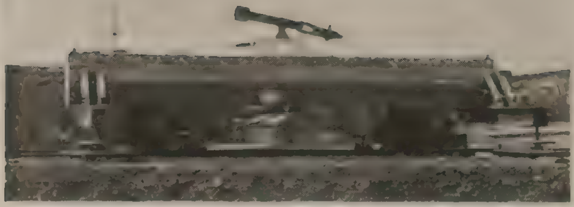
The belt into the house is equipped with a "Merrick" automatic conveyor weightometer. Its chief purpose is to keep track of all coal from storage which does not again pass over the track scales.

A cross-over belt is supplied to reach the far elevator. Magnetic separators are installed in the discharge chutes from the bucket elevators, where the coal drops onto the bunker belts, and automatic samplers are placed at this point.

*"Rooster block" used in handling return cable when tail block car is placed for handling coal from points in storage yard farthest from winding engine*

All of the new equipment, with the exception of the Bradford breaker, is driven by double squirrel-cage induction motors with automatic cut-over type resistance starters and push-button control. On account of the high inertia of the coal breaker, a wound-rotor induction motor is used for this machine with a controller and starting resistance. All the controls are interlocked through auxiliary switches on the contactors and switches on the flop gates, so that if for any reason a conveyor or the breaker stops all equipment feeding coal to it also stops. If a gate is shifted to feed coal to a conveyor or the breaker when they are not running, this automatically shuts down all the equipment ahead of it. In starting up, if the coal is to be sent into the house the conveyors above the bunkers must be started first and the proper se-

*Housings for conveyors, Bradford breaker and drag scraper, winding engine and controls*



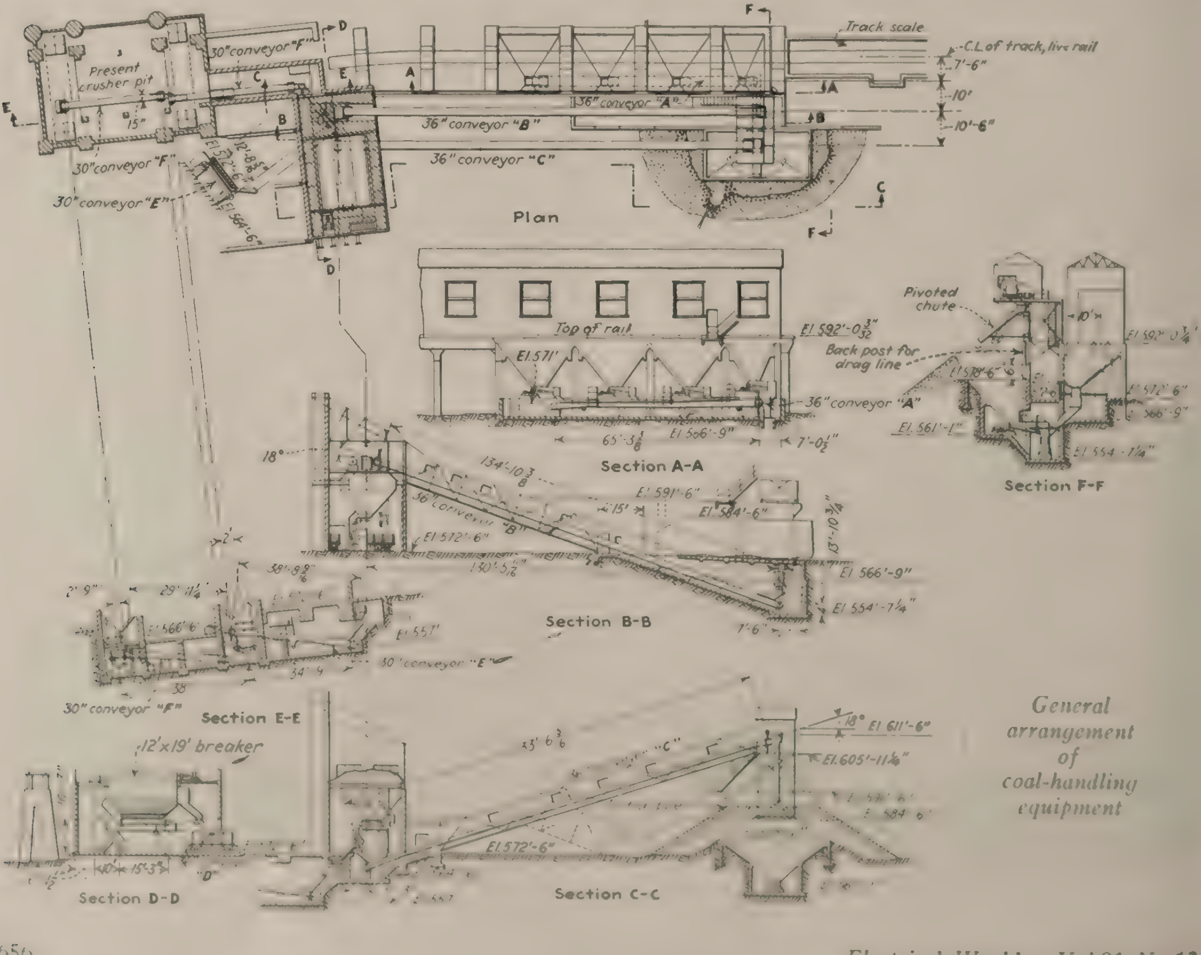
*Tail block car used in distributing or reclaiming coal from any part of the storage yard*

quence followed through to the feeders at the hoppers. In the storage yard the coal in the pile formed by conveyor *C* is distributed about the field by means of a Beaumont drag scraper in the center of one side of the storage area. Around the other three sides is a track on which the movable tail block car may be shifted by block and tackle as required. The tail car, counterweighted with concrete, weighs about 33 tons. In addition to this weight, rail clamps and outriggers are employed to keep the car from tipping. The coal is stored out, or reclaimed, by a scraper having a capacity of 2 tons, which plies back and forth between the front post and the tail car at the will of the operator. The machinery handles coal, either "run-of-mine" or crushed, at a rate of 225 tons per hour at 100 ft. haul. All that is necessary in order to change from storing out to reclaiming, or vice versa, is to reverse the scraper bucket on the cable. The cable after passing around the sheave on the tail car is kept from burying itself in the coal by passing through other fixed blocks (called rooster blocks) located at the corners of the field. One man can control this equipment. The operator's position is above the winding engine and at an elevation such that he has a clear view of the entire storage area. Operation is by a large wheel which controls the direction of rotation of the cable drums through a system of levers and cone friction clutches. A 100-hp. continuous-running squirrel-cage induction motor operates the scraper system. The capacity of the storage area with coal piled 25 ft. high is about 80,000 tons.

To facilitate the removal of frozen coal from the cars, a thawing shed has been provided which has a capacity of six coal cars. Some of the hot gases from either of two boilers are by-passed through this building by means of an auxiliary induced draft fan. Dampers are provided to control the temperature around the cars, and a recording thermometer shows how well this is being done. At a temperature of 200 deg. F. cars are sufficiently thawed in about four hours' time to permit the car gates to be opened.

Practically all of this equipment is external to the main building. Hoppers and trenches below ground are of concrete. The remaining structures are of steel with corrugated asbestos board roofs and siding. The breaker unit itself is inclosed in a sheet-steel dustproof case made up with removable panels.

The new equipment permits putting 300 tons per hour into the house and 500 tons per hour into storage.

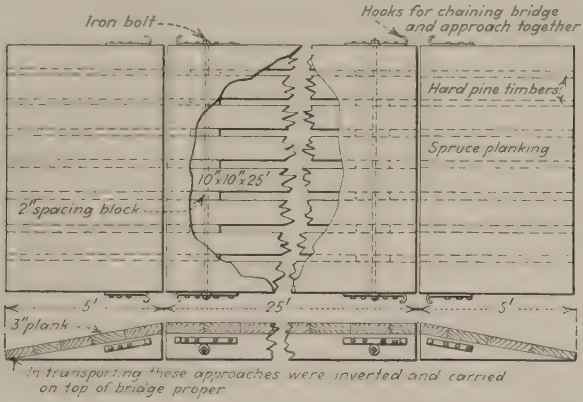


*General arrangement of coal-handling equipment*

# Moving Transformers with a Portable Bridge

By R. G. Kennison
*Central Maine Power Company, Augusta, Me.*

FIVE power transformers aggregating 35,000 kva. in rating and 137 tons in weight were recently transported over a 13-mile route involving the crossing of eight streams, none of which was provided with bridges deemed safe for the loads to be handled. The problem was solved by building a portable reinforcing bridge 25 ft. long, with portable 5-ft. approaches for each end, as shown in the accompanying illustration. Three of the transformers were of 5,000-kva. rating, 66 kv. to 33 kv., and the two others were three-phase regulating transformers of 10,000 kva. each, the individual weights of the two types being 23 and 34 tons. The total cost of the job was about $500, including hire of tractors.



Iron bolt
Hooks for chaining bridge and approach together
Hard pine timbers
Spruce planking
10"x10"x25'
2" spacing block
5'
25'
5'
3" plank
In transporting these approaches were inverted and carried on top of bridge proper

*Portable reinforcing bridge enabled 34-ton transformers to pass safely over existing bridges*

The transformers were transported one at a time on a Rogers 20-ton trailer hauled by one or more tractors. A 14-ton Lombard, 10-ton Holt and Caterpillar sixty tractor were used. The road conditions ranged from partially bare to glazed surface, with deep snow in some places. The ordinary procedure on the level was to hook one or two tractors ahead of the load, all three tractors being required on up-grades, especially if snow or ice was encountered. On down-grades, except on bare ground, it was necessary to hook one tractor on behind for snubbing, the ice and snow rendering the trailer brakes useless.

The transformers were shipped from the factory partly full of oil in order that the coils might be covered and to obviate the need of a heat run before being put in service. As all transformers exceeded 15 ft. in overall height the greatest care had to be taken to center them properly and to fasten them down to prevent tipping over.

The first process was to shore the transformers on the cars upon which they arrived from the factory. They were then moved on rolls from the cars to the trailer, where the shoes were bolted down by hook bolts under the flanges of the I-beams forming the trailer frame. The tops of the transformers were guyed four ways by 1-in. iron rods bolted to the flanges of the I-beams. This made it practically impossible to overturn a transformer without tipping over trailer and all. The shoe was 12 in. high and this, with the height of the trailer from the ground, brought the transformer top about 17 ft. into the air. This made it necessary for one man to devote his entire attention to the removal of wires, service loops and telephone loops encountered along the road. In most cases this was easily done by a man standing on a ladder against the transformer casing and using rubber gloves and a forked stick for pushing the wires up and out of the way.

The portable bridge consisted of eight 10-in. x 10-in. timbers 25 ft. long, fastened together and planked over as shown. This was used to reinforce each bridge in turn as the transformer passed over it. Seven of the bridges were of spans varying from 13 to 19 ft. The portable bridge gave a safe bearing at each end. One bridge was of 30-ft. span and in this case special precautions were taken. The bridge was shored up underneath with a crib pier near its center, and for reinforcement a second portable bridge was made and the two butted together so that the joint came over the new pier. Hardwood plank 3 in. thick would have scored less than spruce had the former been available for flooring at the time.

The portable bridge was transported by a truck equipped with a shear and winch. The winch cable was hooked via the shear to an eyebolt in the front of the portable bridge, and when it was necessary to move it along the road the front end was simply pulled up about 1 ft. from the ground by the winch and dragged along until the next bridge was encountered. The moving was usually done between 6:30 a.m. and 6:30 p.m., the return being made at night with the trailer. Loading was done by a night crew.

---

# Pole-Yard Derrick Saves Time and Labor

A DERRICK used by the Northwestern Electric Company in its Portland (Ore.) pole yard is shown. The boom is 70 ft. long and is swung at a fixed angle by a tag line or by pushing the load. A motor-driven winch operates the whip line. Through the use of this derrick two men can load and unload and move poles about the yard with a great saving in time.

# Government Investigation and the Investor

### Investment banker has no apprehension of what investigation will disclose, but fears business and investment reaction

*An Interview with*
H. P. Wright,
*President Kansas Gas & Electric Company*

"THE successful hunter goes where the ducks are before he begins to shoot. The fellow who goes out into the middle of the street, points his gun straight up in the air and blazes away because he has heard a rumor that there are some ducks around somewhere does not have duck for dinner. But he does attract a lot of attention. Maybe that was his idea all along. Of course, no one except the man who pulls the trigger can truthfully say whether or not he really hoped or expected to get a duck or whether he wanted the noise to awaken the neighbors. But one can form an opinion as to which is the true reason for all the shooting that's going on.

"So far as the properties in which I am interested are concerned, I am positive that any investigation of any kind will not turn up any flagrant moral derelictions in financing, management or in treatment of the customers who pay for service. I believe, also, that by far the greater number of electric utilities in the United States can say the same thing in full consciousness of rectitude and in perfect willingness to account for their every action. In these regards the so-called Walsh investigation which the Senate has committed to the Federal Trade Commission causes me no perturbation. But I do have a real fear that harm will result, not from any disclosures of the investigation, but from the animus of the investigation and manner in which it may be prosecuted.

"There is no doubt of the principal nature of the animus behind the Walsh resolution. It is political. The minority investigates the majority. Democrats investigate Republicans. The pendulum was on the other side of its swing during and immediately after the Wilson administration, when the papers were full of charges of malfeasance and misfeasance in office in regard to the disposition of alien property and to the inflated profits of patriotic (?) manufacturers supplying war materials. Investigations will always be with us so long as the political party not in power can depend on the strength of the vocal cords of its members. This is not to say that some investigations, in fact a large number of them, are not justifiable as well as natural. When an investigation is directed toward specific and definite charges against specific and definite persons or corporations, like the hunter who goes where the ducks are, then there is likelihood that the result will be of worthily corrective nature. But if an investigation, such as that sponsored by the Walsh resolution, has nothing to go on except vague and hazy accusations against the whole body of a national industry, then the result is foreordained to be more harmful than good.

### May Jeopardize Investors' Interests

"The result will be harmful to business in general and to the investing public, which in this day includes a not inconsiderable fraction of the total population of the country. Business will be harmed because the precedent will have been established that governmental prying into private concerns is gratuitous, that competent and specific evidence of wrongdoing is not required to get a federal investigation started; all that is required is for an industry to attain such success and prosperity as to make it a shining target for any one who feels the urge to throw a brick. If the electrical industry is investigated on these unpositive bases, as it appears that it will be, then another industry will be next, and so on. The result will be harmful to the investing public, which, through savings banks and insurance companies, includes a much larger number of people than is generally appreciated, because of the impairment of confidence in the values behind outstanding securities. It is very probable that the stocks and bonds of operating and holding companies that are haled before the commission will be quoted at lowered prices on the markets. It will make no difference whether charges are substantiated or even not made; the market reflects apparent, not always factual, conditions. The assumption is that the defendant is guilty until he proves himself innocent. And will the investigators surround the innocent and discharged defendant with the trumpet blaring and circumstance that accompany his summons before them? Well, every one knows that the accusation of vice gets more newspaper space than does the proof of virtue.

"For these reasons, and not because I fear that any considerable or even appreciable evidence of turpitude will be uncovered, I deplore the investigation and what it portends for American business in general.

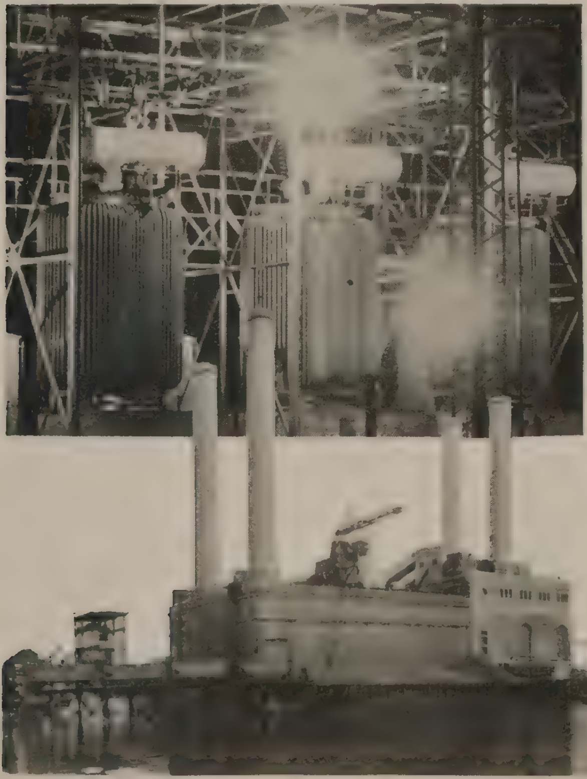
### Already Under State Supervision

"Another thing occurs to me: What are the alleged nefarious acts of electric utility organizations that cause the coldly speculative eye of suspicion to swing in their direction? Are not these acts authorized and permitted by the laws of the states in which they are performed? A baseball game is started under rules fully understood by all the players. A runner gets to second base and some one begins yelling for an investigation as to how he got there, although the umpire said he was safe on first. Yes, he observed the rules as far as we know, but he must have spiked the first baseman or something. We'll investigate and find out if he did or did not do something wrong between the time he hit the ball and the time he touched second in spite of the umpire's ruling at first. We have no evidence that he did do anything wrong, but let's disorganize the game for as long as is required to have an investigation as to whether or not he did play square. A more reasonable course would be to let the player go on, let the game continue, while consideration is given to the rules and to amending them if necessary to make a fairer game hereafter. This is the situation in regard to the electric utilities. They have entered the game and have complied with the rules as laid down and the umpires have declared them safe all along the line. Instead of hindering their progress, governmental effort should be directed to considering the rules of the game. Most states have blue sky laws of one kind or another. All such laws are characterized by one thing, the requirement that securities and companies issuing securities must conform to certain stated conditions. These conditions satisfied, the sale of securities may proceed with the sanction of the state. The manner of satisfaction of these conditions is no one's concern. And sometimes on this account the blue sky law fails of its purpose to protect the investor and he suffers. Would it not be better if, instead of simply setting up conditions to be fulfilled before the sale of securities, the blue sky laws should be made to be actually what they were intended to be, laws against fraud? Would they not be simpler and easier to enforce to their desired end? If any investor in light and power securities has suffered loss from the malicious acts of the issuing company would he not have the same recourse at law as if a counterfeit bill had been passed on him? If any user of electricity feels that the rates he pays are extortionate has he not recourse under the laws of his state?

"The rules and laws of electric utility regulation are everywhere in the United States set up in some kind of governmental, state or municipal supervision. They are the rules of the game and they have been scrupulously observed in ninety-nine cases out of a hundred by the utilities, else their securities could not have been issued and sold. If the game is not going fairly, let's get the rules fixed. We don't have to disorganize the game while we find out if the man on second base got there fairly or not. All that happens then is that the man who yells for the investigation gets a lot of attention from the grandstand."

## Norfolk (Va.) Has $5,000,000 Station

THE Reeves Avenue power station of the Virginia Electric & Power Company is designed for an ultimate capacity of 90,000 kva. The recently completed 42,000-kw. section is shown in the accompanying illustrations. The converging-passage condenser is of the single-pass type and its 23 miles of tubes have a total cooling surface of 27,500 sq.ft. The Newton Park substation, indicated in the night view, is fed by four 1,000-volt, 300,000-circ.mil cables from the Reeves Avenue switch house.



## Transmission Factor of Colored Media Influenced by Temperature

By M. Luckiesh
*Director Lighting Research Laboratory,*
*National Lamp Works of General Electric Company,*
*Nela Park, Cleveland, Ohio*

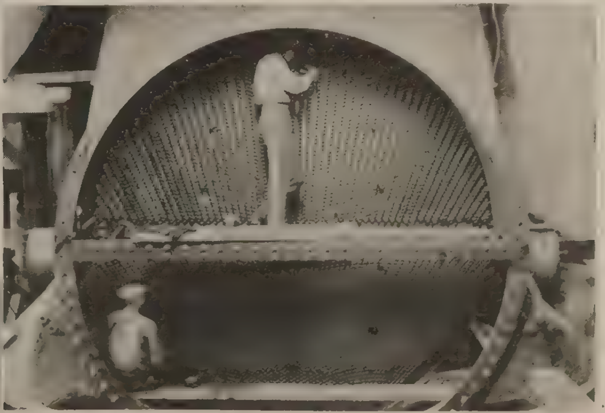
MANY years ago it was observed that the transmission factor of a deep red glass decreased with increasing temperature. Then ten commercial colored glasses were investigated and it was found that practically all of them changed in color and decreased in transmission factor when heated. However, it was found that certain blue glasses (containing cobalt) increased slightly when heated. A deep red glass (containing copper) at 660 deg. F. (350 deg. C.) transmitted only 42 per cent as much light as it did at room temperature, whereas the transmission factor of cobalt-blue glass increased 8 per cent for the same temperature change. Further work with colored gelatines and superficial coatings for lamps show that all of these colored media also change when heated. The color and transmission factor go back to normal when the medium is cooled, excepting, of course, the cases where fading has actually taken place under the action of the heat or light to which the specimen was subjected.

These results are of interest in connection with the photometry and use of colored coatings, colored-glass bulbs and colored accessories for tungsten lamps. When measuring the luminous outputs or transmission factors of colored lamps or colored accessories our practice is to permit them to reach a stable temperature before making the measurements. To illustrate the amount of change to be expected with commercial media some results are presented herewith on red, yellow, green and blue color caps which were used with a 150-watt tungsten lamp of the usual type.

Each unit was photometered in an integrating sphere at regular intervals until the luminous output became constant, which was at the end of about twenty minutes. At that time the transmission factors of the various color caps had changed by the amounts which are shown in the following:

| | | Per Cent | | | Per Cent |
|---|---|---|---|---|---|
| Red | Decreased | 41 | Green | Decreased | 16 |
| Yellow | Decreased | 9 | Blue | Increased | 3 |

The change in color with temperatures encountered in practice is appreciable, but is not as important as the change in the transmission factor.



# 5,000,000 Kva. in Large Transformers Annually

Annual installations by power companies of transformers rated at 3,000 kva. or larger range from about 100 to 500 kva. per 1,000 kva. of generator rating, according to data courteously furnished to the Electrical World by nine prominent power companies. The returns here tabulated came from companies well diversified as to geographical situation, as to size and as to type of territory served; that is, congested urban or widely distributed, the latter demanding long transmission circuits. In generator rating they cover about a sixth of the industry. They are probably fairly representative of the upper 85 per cent of the industry, in terms of installed capacity, or 25,000,000 kva. Although 3,000 kva. was arbitrarily chosen as a lower limit, the table gives sufficient detail to permit of analysis with a higher starting point.

The approximate station rating at the end of 1926 of the companies contributing data was 5,154,000 kva. The new installations of large transformers add up to 1,262,672 kva. in 1926, 1,063,327 kva. in 1925 and 765,416 kva. in 1924. In comparing these totals of new large transformers installed during each year with the then existing generator rating allowance must be made for the annual growth of the latter. The average kilovolt-amperes of the former per thousand kilovolt-amperes of existing generators was 245 in 1926. In 1925 it may be taken roughly at 225, and in 1924 at 175, allowing for the annual change in generator rating.

As might be expected, there is a wide variation between companies and between transformer installations by the same company in different years. Type of territory seems to have little influence, high and low values coming equally from localized companies and from those serving large areas.

Averages are often an unsafe guide and inferences drawn from partial data must be used with caution. With these reservations, and assuming that the average of about 200 kva. of transformers per 1,000 kva. of generators derived from this sample may fairly be applied to the 25,000,000 kva. previously mentioned, a normal year ought to see about 5,000,000 kva. of large transformers installed by the electric power companies of the United States. This does not include installations by railways or manufacturers on their own account.

# Electrically Operated Doors for Railroad Tunnel

Extremely low temperatures, high air velocities and large quantities of moisture in the electrified Charnaduras tunnel of the Bernina Railway, Switzerland, led to continued difficulties with ice formation on tracks and contact conductors. In winter a large staff of men were employed for clearing these facilities. Electrically operated doors, opening and closing automatically, have recently been installed at each entrance. It is stated that the experiment has proved so successful, the temperature in the tunnel never falling below the freezing point, that installations of similar character are planned for use in other Swiss railway tunnels.

*Annual Additions in Transformer Capacity (Units of 3,000 kva. or Larger) in Relation to Installed Generator Rating*

| Company | Approximate 1926 Station Rating, Kva. | Additions to Transformer Installation | | | | | | | | | | | | | | | Kva. Total Transformers Installed (1924-1926, Incl.) | Average Annual Kva. Transformers | Average Annual Transformer Kva per 1,000 Kva. of Station Rating (1924-1926, Incl.) |

# Quality Industrial Lighting*

### Glare a serious factor in manufacturing output considerations. Illumination standards offer basis for analysis of existing conditions. Comparative data indicate value of plan

By Arthur A. Brainerd
*Philadelphia Electric Company, Philadelphia, Pa.*

THE effect of glare, both direct and reflected, on production is a very serious item in many manufacturing operations. Direct glare from bare "Mazda" C lamps on drop cords is, of course, a very common occurrence. An illustration of such a condition is offered in Fig. 1, which shows the appearance of the infants' hosiery division of the Reid Hosiery Company. The improvement indicated in Fig. 2 was secured largely during a correction of glare values. In this case removal of direct glare resulted in a decrease in labor turnover from 43 per cent per month to almost nothing. Direct glare from poorly planned systems of RLM units had also resulted in many complaints. This became so serious in the case of Jacquard looms that it finally became necessary to cover the openings of the reflectors with a diffusing cover glass before the union officials would allow a change in lighting.

The reduction of reflected glare to a low value undoubtedly had much to do with the increase in speed of production in the machine shop of the American Metal Works. The same is true to an even greater degree in the Decorative Lamp & Shade Company's woodworking shop, and the B. Wilmsen Company. In all these cases great care was taken to reduce this glare to a minimum.

*Figs. 1 and 2—Before and after views in mill manufacturing infants' hosiery*

Correction of glare conditions in this plant practically eliminated a labor turnover of 43 per cent per month. At the same time the output was increased 6.25 per cent.

The tests here recounted were of such a nature that it was impossible to separate the variable quantities. General observations throughout the tests, however, indicate that the measurement of reflected glare and its influence on productive operations would make a very profitable subject for future research studies.

There is also reason to believe that the present open type of steel reflectors introduces a high degree of both direct and reflected glare, especially when extremely high intensities are used.

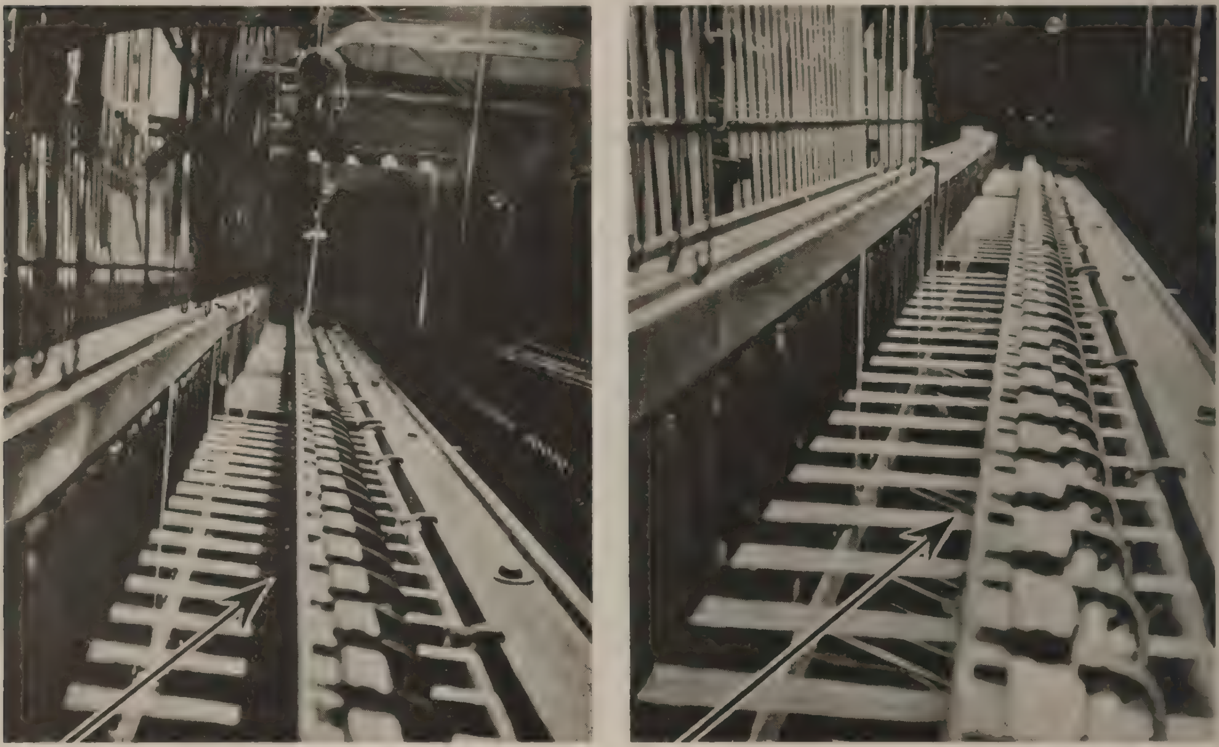
Localized general lighting becomes almost out of the question in many cases when lamps of 200 watts or larger are used in connection with RLM domes or "Glassteel" diffusers. In the case of the Sidebotham mills, however, where we are at present experimenting with foot-candle intensities varying from 40 to 50, the operators experience no discomfort, since the illumination is totally indirect. In fact, they are enthusiastic over the arrangements. In the same location the glare from "Glassteel" diffusers becomes very annoying at 20 foot-candles. Illumination intensities of the order given above could hardly be used in a room with such low ceiling height with open reflectors.

There seems to be no question that before we can profitably carry industrial illumination to intensities of 30 foot-candles or over there must be developed some new form of lighting units that will retain the efficiency and rugged character of the RLM dome and still have much better diffusing qualities.

---

**The second and final part of an abstract of Mr. Brainerd's paper "Quality Measurements in Industrial Lighting Calculations," which received the James H. McGraw N.E.L.A. award for merit. The first installment appeared in the Feb. 4, 1928, issue of "Electrical World" and outlined the basic problems of industrial illumination.*

The purpose of this discussion is not intended to discount the value of adequate illumination intensity, but merely to call attention to the fact that intensity is only one of several things to be considered. The accompanying curves show the effect of increasing the intensity of illumination both on over-all production and speed of handwork. In the case of the American Metal Works the remarkable rise in the speed of handwork is probably due to the fact that there were no facilities available to determine accurately the percentage of handwork that depended upon manual skill and not on seeing. It will be noted that in both cases both the over-all increase in production and the increase in speed of handwork closely follow Fechner's law.



*Figs. 3 and 4—Tape loom before and after installation of good lighting*

Eliminating the sharp shadows, indicated by the arrow in Fig. 3, increased production 7.7 per cent, although the illumination intensity was increased only 1.1 foot-candles. Later the illumination intensity was increased to 12, 20, 30 and 40 foot-candles, but no increase in output was noted above 12.

There is no doubt that the prevailing illumination intensities of 1 to 5 foot-candles are ridiculously low. They must be raised appreciably before production can attain its maximum, but proper attention must first be given to improving the quality of the illumination.

On the other hand, a series of studies conducted at the John Sidebotham plant (see Figs. 3 and 4 above) covering a period of nearly two years seemed to indicate that there was no justification from the production standpoint for using illumination intensities higher than 12 to 20 foot-candles. Five different levels of illumination—8, 12, 20, 30 and 40 foot-candles were used in this test, and as the system was totally indirect, the items of glare and shadow were eliminated entirely.

*Value of Product and Production.*—In laying out a system of productive illumination we must never lose sight of the fact that money spent for good lighting is to be considered as an investment rather than an overhead expense, and the amount of profit made in a given area in a given space of time will determine to a certain extent the amount of money that can profitably be invested in lighting. Consulting the tabulation, it is quite evident that a manufacturer of high-grade silk hosiery can consistently spend far more money for illumination than a manufacturer of cheap dress goods. In one case investigated, the Shen Manufacturing Company, a preliminary test indicated a possible increase of 15 per cent in production at an increased operating cost equivalent to 12.65 per cent of the payroll. Such an investment would be a business venture of doubtful value and it would be futile to recommend any such course of action.

In view of these facts it would seem reasonable to establish a certain percentage of the payroll as a maximum that could safely be invested in good lighting under standardized conditions. To be sure, a large percentage of the plants today are operating on some sort of a piece-rate basis, but the benefit of having a contented force of workers who are easily supervised is a real item to be considered, not to mention the reduction in overhead which an increase in production always brings about.

*Height and Spacing.*—In determining height and spacing it is quite evident that as far as increase in production and decrease in spoilage are concerned the working area alone is to be considered and an average room intensity in any plant is meaningless. If we mount overhead units in such a position as properly to illuminate machine tools to a 20 foot-candle intensity throughout the working area, which may be a circle 4 ft. or more in diameter, it is quite obvious that there will be sufficient illumination in the aisles. Such an intensity will provide sufficient illumination for reading micrometers and steel scales. As long as the worker does not normally lift his eyes outside of the high-intensity area, it is clear that a high foot-candle value in the passageways is useless. Mounting height of 8 ft. will be found sufficient when outlets are equipped with 150-watt bowl enameled lamps in RLM domes.

*Method of Predicting Production Increases.*—Our present knowledge of the application of light to manufacturing operations is far from complete and in many cases we are obliged to depend more on personal judgment than on any definite method of analysis when we prepare plans for productive lighting. There is a wealth of excellent lighting equipment on the market the possibilities of which we have failed to make use of. Moreover, when selling good lighting to industrial executives, we talk increased production, but when pinned down to facts we cannot predict with any degree of assurance just what good lighting will do in any particular industry.

*Figs. 5 and 6—Inspection perch in plush mill*

Replacing clear lamps with bowl enameled increased production 42 per cent with only 25 per cent increase in foot-candle intensity. Note softness of shadows as indicated by arrow in Fig. 6.

For the purpose, therefore, of reducing lighting recommendations to a more exact basis, even though the method is far from being scientifically accurate, it may be well worth while to set up some sort of empirical formulas that will best harmonize with the results secured in the investigations under consideration. First let us list separately each item that affects the character of the lighting installation and assign to each an arbitrary value.

Experience has shown that sales of better lighting may be divided into three distinct classes.

1. The customer has fair illumination and wishes to install the best that can be had.
2. The present installation is bad and the customer will consider only fair illumination.
3. The present installation is very bad and the customer wishes the best illumination.

For purposes of estimation let us assume that fair illumination will produce approximately one-half the increase in speed of handwork that can be secured when the lighting has been brought to the very highest standard that our present-day knowledge of lighting affords.

The factors that determine the degree to which speed of handwork is influenced by illumination are variation factor, density of shadows, reflection characteristics of the surface, background contrast, visual angle of objects viewed and amount and character of natural illumination.

If the existing system of lighting is bad, let us assume that if the variation factor is over 3, fair lighting by reducing this factor will increase speed of hand operations 5 per cent and excellent lighting 10 per cent.

If, on the other hand, the variation factor lies between 2.25 and 3, fair illumination would effect no increase in speed and excellent illumination only 5 per cent increase. When this factor is below 2.25, no appreciable increase in production is to be expected by reducing it, except under extreme conditions.

In order that we may have some specific standards for use in our calculations, poor, fair and excellent illumination are defined as follows:

| | |
|---|---|
| Visual angle above 3 | |
| Bad | Below 3 foot-candles |
| Fair | 3–7 foot-candles |
| Excellent | Above 7 foot-candles |
| Visual angle 1.1 to 3 | |
| Bad | Below 5 foot-candles |
| Fair | 4–9 foot-candles |
| Excellent | Above 9 foot-candles |
| Visual angle below 1.1 | |
| Bad | Below 7 foot-candles |
| Fair | 7–14 foot-candles |
| Excellent | Above 14 foot-candles |

No installation of bare lamps less than 16 ft. from the floor is considered good illumination. When the walls and ceiling are exceptionally light experience shows that the net effect on night operation is equivalent to fair natural illumination.

Referring to Table II, page 251, Feb. 4, 1928, ELECTRICAL WORLD, it will be noted that all factors referred to have been assigned arbitrary constants, corresponding to the different conditions under consideration. No claim is made for the absolute accuracy of these constants, but it must be recognized that the results secured from their application correspond very closely with the actual results secured from production tests.

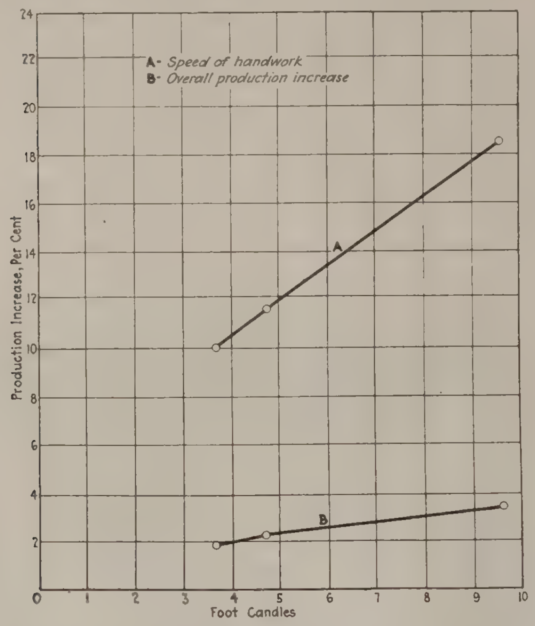


*Fig. 7—Variation of production with illumination intensity; webbing looms Manning J. Smith Belting Company*

Take, for example, the case of the Realart Silk Hosiery Company, and let us analyze the case as follows:

| | |
|---|---|
| Old illumination | Fair (7.2 foot-candles) |
| New illumination | Excellent |
| Variation factor | 2.2, add 0 per cent |
| Shadows | Dense, add 5 per cent |
| Reflections | Specular, add 5 per cent |
| Background contrast | 33 per cent, add 5 per cent |
| Visual angle | 0.532, add 4 per cent |
| Natural illumination | Fair, add 5 per cent |
| Total estimated increase in speed of handwork production | 24 per cent |

Substituting in the equation previously given,* we have

$$\left(\frac{M_2 m_1}{M_1 m_2} - 1\right) \times 100 = 24$$

$$\left(\frac{M_2 \times 26.8}{73.2 \times m_2} - 1\right) \times 100 = 24$$

$$\frac{M_2}{m_2} = 3.39$$

$$M_2 - 3.39 m_2 = O, \text{ and } M_2 + m_2 = 100$$

Solving, $M_2 = 77.1$ and $m_2 = 22.9$

Estimated increase in production

$$\frac{77.1 - 73.2}{73.2} \times 100 = 5.33$$

This system of analysis was first applied in one case, before the old system of illumination was changed, in an effort to determine whether or not the conditions justified the expense of a test. With the constants then in use an increase in production of 6 per cent was estimated. Actual increase in production, according to factory records, was 5.75.

For daytime operation the above estimate for increase in speed of handwork would be 5 per cent lower, since the natural illumination is fair and the shadows medium.

If the original illumination had been bad from the standpoint of intensity, all of the constants except that for shadows would have been doubled. Experience shows that a mere softening of shadows may be expected to bring about soon an increase in speed of handwork of the order of 7.5 per cent.

Two other checks on the accuracy of the system were made before the present series of constants was completed. One was the case of the Sidebotham mills, where 7.5 per cent increase in production was predicted and the test showed 7.7 per cent. The other case was that of the M. J. Smith Company, where 5 per cent was predicted and 3.74 per cent measured.

The results attained in applying this method to seven installations were indicated in Table II (ELECTRICAL WORLD, Feb. 4, 1928, p. 251). Using the arbitrary standards, it will be seen that of these fourteen cases the estimate was low in seven and high in seven. The average percentage of error is +6.66 for the fourteen cases studied.

The range of error in all but two cases is within reasonable bounds in view of the large number of variables involved. In the case of the M. J. Smith Company the error in percentage seems large, but the over-all increase in production in this case is so small that the chances of error were unusually great in spite of all precautions taken in securing accurate data. This method of analysis, however, would have quickly shown the lighting engineer that production increase should not be stressed in attempting to sell better lighting in this instance.

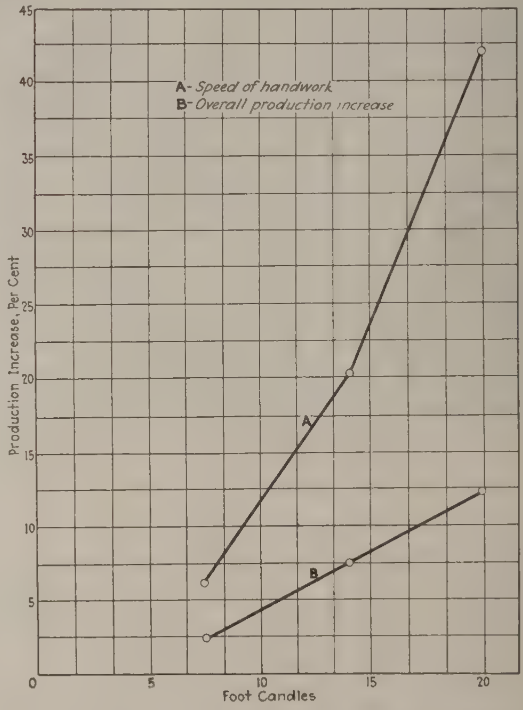

*Fig. 8—Variation of production with illumination intensity; turret lathe American Metal Works*

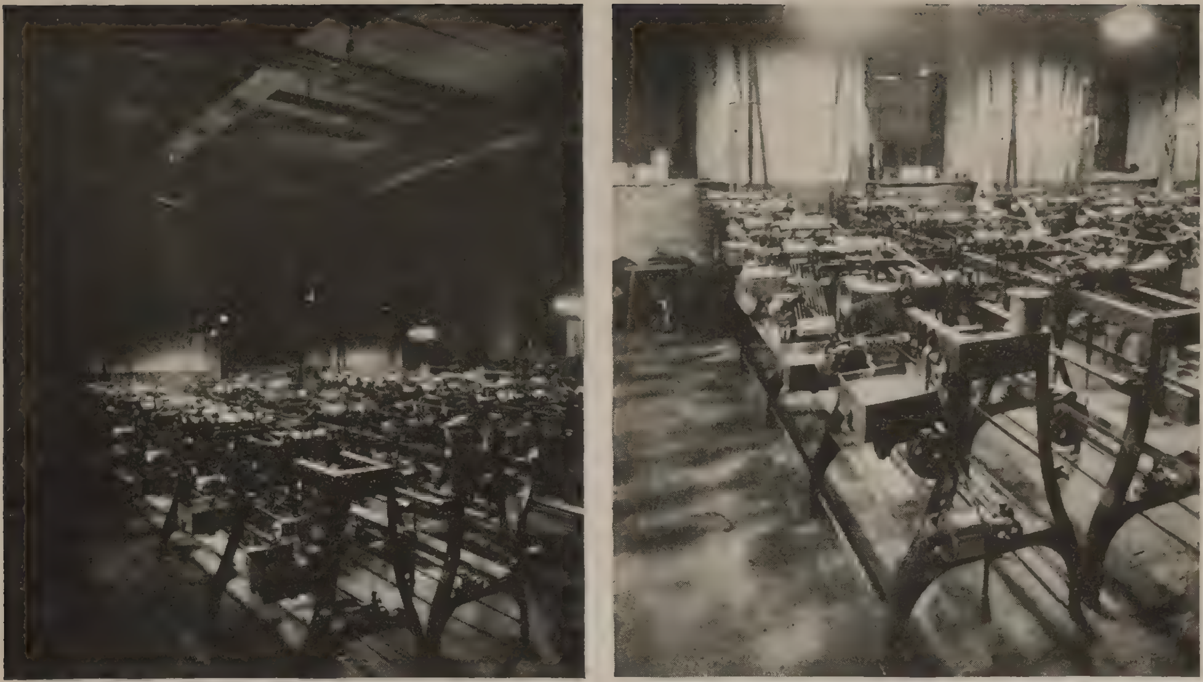
In the case of the John Sidebotham mills, it is probable

---

*ELECTRICAL WORLD, page 249, Feb. 4, 1928.



*Figs. 9 and 10—Before and after views of wire drawing machines in plant manufacturing Christmas tree tinsel*

Note extreme glare conditions under old system. Good lighting increased the output of this plant 16 per cent.

that the indirect system of illumination would by its superior quality increase production to a much greater degree than the same intensity of direct lighting. Since no other installation of indirect illumination was available for comparison, there was no basis for making this allowance.

In general this method of calculation has proved quite valuable in practice and where records for checking are available the error is practically always less than 25 per cent. An experienced lighting engineer by exercising personal judgment in the use of the constants can in most cases arrive at an even closer estimate than a rigid use of the system will give.

The ultimate aim of all such research is to classify industrial lighting conditions so definitely that a lighting engineer will be able to approach a factory executive with sufficient information at hand to enable him to predict, within a reasonable percentage of error, the economic saving that can be expected from a scientific lighting system.

However much we may talk of improved morale, decreased labor turnover and decreased accidents, increase in production is the most powerful argument for better lighting that we can put forward and one of the easiest to demonstrate by actual test.

From the data recorded in this paper it is evident that in the design of industrial lighting such items as variation, factor, shadows, reflection, background contrast, visual angle and natural illumination are fully as important as mere foot-candle intensity, and probably more important. Instead of leaving these items to mere personal judgment, some method should be developed that will enable us to allow for these features quantitatively.

The method of estimation here described is intended only for an approximation. In many cases it has been possible to arrive at a fairly accurate value for the portion factor, shadows, reflection, background contrast, speed of vision and not solely on manual skill. No attempt has been made, however, to separate visual acuity and ability to sustain speed of vision. The remarkable increase in speed of handwork noted in some machine operations was undoubtedly due in part to the fact that the eyes were required to work only for a small portion of the time.

All the factors considered in the empirical method of prediction are capable of exact measurement, but it will probably be several years before this research is completed. Dr. Ferree and Dr. Rand have already measured the variation of speed of vision with different visual angles and background contrasts.

A complete analysis of these items will no doubt result in a much more accurate method of calculation. Since considerable time may elapse before such research is completed, this system is offered as a possible method of at once placing such estimates on a definite basis and also as a step toward some final formula for predetermining the increase in production to be derived from good illumination.

## Microphone Control of Traffic Lights

THE city of Baltimore has recently placed in service a trial installation of motorist-controlled traffic lights. The signal light is said to solve satisfactorily the twofold problem of safeguarding and facilitating the traffic movement, an accomplishment which automatic signals operating at definite predetermined time intervals fail to do.

The development is particularly adapted to duty at the intersection of a busy highway with a road of relatively low traffic density. A three-color, red, green and yellow system is used. The normal indication for traffic on the main road is green and on the side road red. These signals remain constant until an automobile approaches the intersection from the side road. A microphone is located in advance of the crossing on the side road on each side of the main highway. The motorist, forced to slow down by the red signal, passes the microphone at low speed and in doing so sounds his horn to clear the signal. This sets a time relay in operation, causing the signal to change successively from red to yellow and to green, with inverse indications for the main highway. The green signal is held automatically for a predetermined number of seconds and the system is then returned to its original indication by relay actions.

# Utility Finances House Wiring for Contractors

SOME FIFTY electrical contractors in St. Louis have taken advantage of the Union Electric Light & Power Company's offer to finance house-wiring contracts and thereby assisted in bringing electric service to unwired houses. Under this co-operative arrangement, the electrical contractor may install wiring and fixtures in houses already built, and, upon satisfactory completion of the work, obtain prompt payment from the company, which, in turn, will collect from the purchaser in monthly payments. This agreement covers the installation of wiring and fixtures in homes already built or the installation of additional wiring and fixtures, but, so far, does not cover fixture work only.

The plan operates as follows: Upon developing a prospect for wiring and fixture work, the contractor forwards to the company's office a service and credit inquiry form completely filled out with the necessary information as to the purchaser's location, nature and cost of work, credit data and so forth. The company immediately investigates and notifies the contractor as soon as credit and availability of service have been established. This is usually completed within 24 hours after receipt of the inquiry from the contractor.

Upon completion of wiring and fixture installation, and after such work has been inspected and approved by the municipal authorities, the contractor sends to the company's office:

(a) Contract for the wiring and fixtures completely filled out in ink and signed by the purchaser and the contractor.

(b) Initial payment of at least one-twelfth of the face value of the contract.

(c) Contractor's bill for work made out for the face value of the contract, less 8 per cent.

If the contractor desires that his money be forwarded by mail, an assignment of claims for payment on the back of the contract is signed by him prior to forwarding the contract to the company's office. The contractor, however, does not secure the purchaser's signature to the order for financing the payment which is on the back of the contract, but a representative of the company secures this signature after the contract has been turned over to the company and the work has been completed to the customer's satisfaction. Contracts are approved for payment to the contractor after the purchaser's signature to the order for financing payment and the approval of the municipal authorities have been checked.

As will be seen from the conditions of the plan, the Union Electric Light & Power Company makes a charge of only 8 per cent to cover its bookkeeping, inspection,

*Printed on 4 x 8½ slip with blanks for filling in.

*Nature of Notice* Sent to Contractor to Proceed to Wire*

UNION ELECTRIC LIGHT & POWER CO.

Replying to your inquiry of . . . as to availability of electric service for . . . kw. at premises . . . street and approval of credit in amount $ . . . for electric wiring and fixtures to be installed in above premises under a contract to be signed by . . . you are advised as follows: . . .

Note:—In cases where service is available and credit is approved, we will accept order for financing of wiring and fixture installation during duration of House Wiring Campaign.

Such order will not be accepted: (1) in locations where electric service is not available; or (2) in cases in which credit is not approved; or (3) when order is received by us after close of House Wiring Campaign.

---

*Printed on 8½ x 11 sheet with sufficient space where blanks are indicated for filling in.

collection and other carrying costs. The six features of the contract are:

Contractor shall install outlets for connection of electric service and meter loop for installation of meter at points approved by Union Electric Light & Power Company.

Purchaser agrees that the cutting of walls, floors, baseboard, etc., is a necessary part of the work to be performed under this agreement, and contractor shall be responsible only for unnecessary damage to buildings or decorations.

Purchaser shall locate all outlets before installation hereunder is started, and contractor shall not be required to change location of outlets or fixtures after the work is started.

Purchaser agrees that failure to meet any payment, when due, shall render the installment feature hereof void, and the remaining balance shall become due and payable immediately.

In consideration of company advancing payment due contractor by purchaser for installation made upon above premises, purchaser agrees to contract for and use, or to have tenants contract for and use, the electric service of the company in the premises covered by this order for at least one year and until all payments to company as herein provided shall have been made.

It is agreed by purchaser that, in accepting this order for financing payment to contractor, company assumes no responsibility or liability for the performance or lack of performance by contractor of his obligations under the aforementioned contract for installation of wiring and fixtures, and purchaser agrees to hold the company harmless for all damages due to defective work or material or other causes resulting from performance of contractor's obligations.

Note: The form for electric wiring and fixtures carries thereon an order for financing payment, which is signed by the purchaser, and an assignment of claims for payment, which is signed by the contractor.

## Commercial Lighting Yields Largest Return on Cambridge Rate

THE rate base of the Cambridge (Mass.) Electric Light Company computed on 1926 operations and determined on the reproduction-cost-less-depreciation theory is $8,035,469, according to recent testimony of Edward J. Cheney, New York, consulting engineer for the company in its recent rate case before the Massachusetts Department of Public Utilities. During that year the company sold 53,675,929 kw.-hr., of which 14,115,232 kw.-hr. was for metered lighting service and 34,576,077 kw.-hr. for general power uses. About 150,000 persons reside in the territory supplied by the company either directly or at wholesale. The accompanying table gives the revenue, allocated expense and amount of return on each class of business during the year above named. The total amount available for return, surplus and contingencies was 8.274 per cent of the rate base. In the determination of the rate base, the total physical property value was found to be $6,210,469; organization, $275,000; going concern value, $1,100,000, and working capital, $450,000.

RETURN AND COST TO SERVE CAMBRIDGE BUSINESS DATA FOR YEAR 1926

| Class of Service | Rate Base 12/31/26 | Revenue | Allocated Expense | Amount for Return | Percentage Return on Rate Base |
|---|---|---|---|---|---|
| Residential lighting...... | $2,224,175 | $510,811 | $365,368 | $145,443 | 6.539 |
| Commercial lighting..... | 1,451,349 | 487,631 | 238,154 | 249,447 | 17.189 |
| Domestic and commercial refrigerating and cooking.................. | 68,151 | 13,890 | 11,140 | 2,840 | 4.167 |

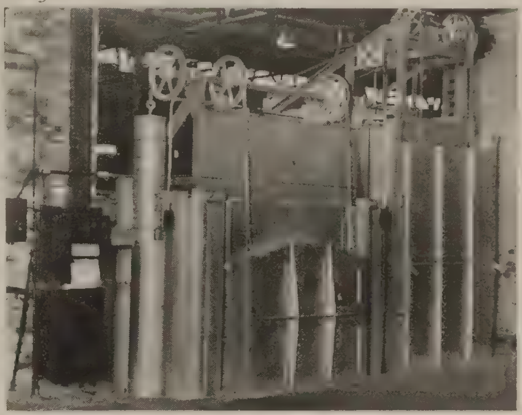
# Large Carburizing Furnace Secures Recuperative Economies

By W. J. Diederichs

*Industrial Heating Engineer*
*Westinghouse Electric & Manufacturing Company*

A LARGE, single-end, box type furnace and a recuperating chamber, both of special design, have been combined as a unit for the carburizing and normalizing of machine tool parts with notable operating economies.

The furnace has an electrical input of 81 kw. for operation on 220-volt, three-phase power supply. By means of a switch the input can be reduced to 27 kw. for use during holding periods. Heating elements are located on the side walls, in the arch and on the floor between the channels, thus insuring uniform heat application during long heating periods. Alloy guards are provided for the side elements in order to protect them from any possibility of injury, even though work were to roll off a tray. The floor elements are protected by alloy floor plates. The recuperating chamber is designed to permit the trays of work to be carried at two levels, one above the other. The door of the recuperating chamber, as indicated in the illustration, is built in two sections and provided with a latching mechanism to make it possible to move the top half alone or the united parts as a single door.



*Furnace-recuperative-chamber unit offers operating savings*

In operating the furnace a loaded tray with cold charge is placed on the upper deck of the recuperating chamber. A heated charge is removed from the furnace at 1,650 deg. F. and immediately charged onto the lower deck of the recuperating chamber. Transfer of heat takes place to such an extent that while a charge in the furnace is being heated the cold charge in the recuperating chamber has been preheated to 600 deg. F. or more. The cooling charge is then removed from the bottom deck, to be replaced as rapidly as possible by a fresh hot charge from the furnace; the preheated charge from the upper deck is charged into the furnace and a fresh cold charge is placed on the upper deck. The manipulation of these trays as indicated above is rapid and efficient due to the use of the special crane.

The equipment is designed to handle 3,000 lb. of gross carburizing charge, or 3,000 lb. of net material to be normalized, per tray. The heating cycles vary considerably, depending upon the nature of the work in hand. Based upon average procedure, the following results are typical of those attained:

The power consumption for carrying out a twelve-hour carburizing cycle on a 3,000-lb. charge at 1,650 deg. F. is 400 kw.-hours, which is equivalent to a gross economy of 7.5 lb. per kilowatt-hour.

The power consumption for carrying out a normalizing heat on a 3,000 lb. charge at 1,650 deg. F., requiring approximately nine hours in the furnace, is 340 kw.-hours which is equivalent to a net economy of 8.8 lb. per kilowatt-hour.

# Simplification of Carbon Brushes

## Multiplicity of grades, sizes and styles of brushes puts unnecessary burden upon manufacturer and user. Simplification offers possible saving of 50 per cent

By E. A. Williford
*Manager Carbon Sales Division National Carbon Company, Cleveland, Ohio*

SINCE the introduction of carbon material as a current-collecting device on commutators and slip rings the determination of the size of these carbon brushes has been left entirely to the discretion of the designing engineer. So far as can be ascertained no class in electrical machine design at any of our technical colleges lays any stress upon the selection of the carbon brushes other than on the basis of friction and carrying capacity. The size of the brush is usually determined by its supposed carrying capacity, the length being chosen either on the basis of a space factor or to be as long as possible consistent with general appearance. As a result, this has led to literally thousands of sizes and styles of carbon brushes, for which there is no engineering justification. To make this situation more complex, there are probably 500 grades of brushes available on the American market from which the designing engineer may make his selection, thus multiplying the possible combinations of brush grade, brush size and brush style almost without limit.

### Brushes Made From Buyer's Specifications

As a result all carbon brushes have to be manufactured to the purchaser's specification on a special order at the time the customer orders his material. There is no such thing as shipment from stock in case of carbon brushes except in a few minor instances. This leads to small-quantity production, on which there are required from six to thirteen machine set-ups on orders ranging anywhere from two brushes up. It is impossible for the brush manufacturer to make up brushes in small quantities except at exorbitant costs, and this has led to the very bad practice of selling a small quantity of brushes below manufacturing costs rather than asking the customer to pay what look like an unwarranted charge.

Moreover, the customer in need of immediate delivery of brushes must wait until this very necessary accessory can be manufactured especially for him and, in many cases, the complete specifications are lacking, leaving entirely too much to the guesswork of the brush manufacturer. If for any reason brushes made up do not fit the brush-holder or the machine for which they are purchased they are a total loss, as they cannot be reprocessed and supplied on some subsequent order. Under these conditions it can readily be seen that industry is bearing a rather heavy burden of wastefulness owing to the multiplicity of sizes and styles of carbon brushes and brush shunts.

The real limiting factor in the selection of a commutator brush is commutation. The only dimension of the brush that has any effect on commutation is the thickness. Even here some latitude is possible, since commutation depends largely upon the number of coils short-circuited at one time, and hence the thickness of a brush may vary by almost as much as the width of the commutator segment without changing the number of short-circuited coils. The width of the brush is determined by the carrying capacity of that particular grade and the demand governed by the output of the machine. This carrying capacity of carbon brushes is a decidedly indefinite quality and is usually based upon safe operating temperatures secured in operation of a well-designed machine. The heating due to commutated current in the coils and that due to friction of the brushes sliding on the commutator are far more important in limiting the carrying capacity of the brush than the heating due to the load current itself. Considerable latitude, therefore, may be given on this matter of carrying capacity. For instance, four brushes 1¼ in. wide may carry the same current which may have been carried in the past by five brushes 1⅛ in. wide. The selection of the length of the brush concerns the length of wear almost exclusively and, in the interests of simplification, broad concessions should be made in this dimension.

### Many Styles of Shunt Attachments

There are many styles of shunt attachment, almost any one of which is satisfactory for the use to which it is put. Where a brush-lifting device is required, such as for rotary converters starting from the alternating-current side, this matter could be simplified by an exchange of patents, as it is doubtful if there is any real engineering advantage in one form over that of another. They all do the work for which they are designed, and it would seem that the commercial advantage of fewer types of such mechanism should far outweigh any engineer's ideas as to the advantage of his novel idea. The length of shunt and style of terminal could be particularly well

## Ban on Power Export Costly to Public

"THE inability to sell, at any price, such surplus power as we may have from time to time is a very great drawback to our industrial development. Whenever a power plant is built it must be built larger than is immediately needed, and under the present conditions the service is obliged to go absolutely to waste until local customers absorb it. This means that the people of Maine pay more for their power in the average year than they would do if this waste power could be sold, no matter at what price it is sold."

*From a statement to stockholders by* Walter S. Wyman, *President Central Maine Power Company.*

standardized in two or three lengths and perhaps seven or eight styles of terminals for practically all applications larger than fractional-horsepower motors.

The advantages to be gained through simplification would accrue largely to the brush consumer; he would have a much smaller inventory to carry as spare parts in his store room; the interest charges on this investment would be reduced; he could secure quicker delivery of materials which he needs; he would be able to order the few styles he requires in larger quantities and save perhaps as much as 50 per cent in the unit cost of such brushes; brushes could be catalogued so that one particular size and style of brush would bear this standard catalog number, specifications of which would be known to all brush manufacturers and motor generator manufacturers, leaving only the necessity of specifying the grade that the consumer feels to be best adapted to his application. There are very few distributors in the brush business today due to the fact that it is not an economical proposition to stock brushes of so many varying types and qualities. If these styles were reduced to a smaller number brushes could be carried in stock by electrical jobbers for distribution to the small consumer and to isolated industries, such as coal mines.

The motor and generator manufacturers would have fewer styles of brush-holders, thereby reducing their own inventory charges and simplifying the stock problem. They would have greater interchangeability of brushes for different types of machines and would not need to place orders for brushes so far in advance, as they now must do in order to secure prompt deliveries. These savings in the cost of machines would undoubtedly be passed on to the ultimate consumer, but with some compensation to the manufacturers themselves.

The brush manufacturer would benefit chiefly to the extent of eliminating the risk and waste to which he is now subjected in making up every order after the receipt of the customer's order itself. He would be able to mold individually the most important sizes of brushes, resulting in a more uniform product at a lower cost, which, in turn, would be passed on to the motor and generator manufacturers and to the brush consumers. Brushes could be placed in stock and shipped promptly upon receipt of customers' orders. Where brushes have been ordered through error on the part of some customer, they could be placed back in stock by the brush manufacturer instead of being scrapped, as now is done. Mass production would replace the present small order type of production and enable the American manufacturer to compete with the foreign manufacturer in foreign markets.

## Realizing Flexibility in a Holding Company "Set-Up"

EARLY in 1927 a number of closely affiliated gas and electric utilities serving the Connecticut Valley and other parts of western Massachusetts organized a voluntary association designated as the Western Massachusetts Companies. These now include the Turners Falls Power & Electric Company, United Electric Light Company (Springfield), Greenfield Electric Light & Power Company, Pittsfield Electric Company, Amherst Gas Company, Ludlow Electric Light Company, Easthampton Gas Company, Agawam Electric Company and Lee Electric Company. The operation of these properties, with combined assets over $36,000,000 has been centralized and co-ordinated along the lines illustrated in the accompanying chart, the general policy being to maintain the individuality of local administration hitherto enjoyed by these constituents, along with their pooled financial, equipment, operating, executive and other resources.

The chart is practically self-explanatory. The trustees administer the association on behalf of the stockholders of the constituent companies, the immediate conduct of affairs being in the hands of an executive committee working in harmony with the directors of the local properties and through the president and vice-presidents of the holding organization. The administration of each constituent property centers in its local or resident manager, through whom contact is made with the headquarters staff officers and executives of the association. General jurisdiction over local company departments is exercised by specialist executives available to local managers on the one hand and over local departments on the other. The treasurers and comptrollers contact through the local managers with the subsidiary properties and also by direct line with the accounting departments of the constituent companies. The director of economics and engineering exercises the functions of a technical consultant for the association and its properties besides having executive charge of all electrical and hydraulic engineering activities with specialist executives reporting to him. These examples and examination of the chart will show that an unusually flexible and compact organization has been set up to allow the utmost freedom of co-operation between the officers and specialists of the association and of the constituent utility companies.

*Maximum flexibility in administration and advisory functions is attained by this set-up*

The chart is functional in its arrangement, and in some cases the same individual fills an office in a constituent company that he occupies in the association. Thus, the director of engineering indicated on the chart for each local company holds this post in the association general staff. The size and make-up of the local staff depend on the conditions in each local company.

## *Price Cutting the Seller's Fault*

*To the Editor of* Electrical World:

Apropos of Earl Whitehorne's article in the Feb. 18 issue of Electrical World, entitled "Who Pays the Cost of Price Cutting?" the following is the reaction of a comparative newcomer in the ranks of the purchasing agents:

I hold no brief for those purchasing agents who are "beating down price levels by ingenious methods of induced competition." Such tactics will continue so long as the manufacturers "weakly submit to this pressure," but I seriously question the efficacy of the remedy proposed by Mr. Whitehorne, namely, the elimination of the secrecy of bids. My experience has been that the practice of requesting sealed bids has done more toward eliminating the unethical tactics of manufacturers' representatives than any other single consideration, for only a purchasing agent knows of the hundred and one subtle devices that are used in an effort to worm out of him the low bid price. Where sealed bids are used the purchasing agent has no other alternative than to give the order to the low bidder, quality of material and delivery being equal. To throw the bids open to examination by a competitor is to invite collusion between manufacturers, leading to efforts to make the buyer pay all that the traffic will bear.

Mr. Whitehorne's Utopian one-price system will hardly commend itself to any fair-minded buyer, for the simple reason that such a system is seldom if ever based upon the costs of the most efficient unit in a given branch of industry, but rather upon the costs of the more inefficient. The buyer is, therefore, forced to pay for the high costs inherent in obsolete machinery, worn-out manufacturing methods, slipshod cost accounting, topheavy overhead and inefficient distribution.

What, then, is the remedy for the admitted evils of price cutting? Quite frankly, I feel that the initiative should be taken by the manufacturers themselves, in desisting from their unethical practices of stealing business from their more efficient competitors by a ruthless cutting of prices. The inefficient manufacturer who cannot compete with his more efficient competitor has only one alternative to falling by the wayside, and that is to lower his costs. There is plenty of room for this in 90 per cent of electrical manufacturing plants.

Furthermore, the manufacturers should employ a few good salesmen rather than a flock of mediocre order takers. The right kind of selling organization would be able to evaluate such intangibles as better quality, prompt service, longer life, etc., in terms of dollars and cents, which is, after all, the deciding factor in a hard-headed, clear-thinking executive's mind. The purchasing agent would then buy not on the basis of price alone, but with due consideration for the other factors above mentioned.

I have no objection to showing a bidder the other prices when he is asked to reduce his price, provided that the identity of the bidder is not revealed, for to reveal the identity of the bidder is a breach of confidence of which the manufacturers themselves would be the last ones to approve. It seems to me that the personality of the purchasing agent is the governing factor, for I have yet to recall an instance where my word was questioned when I have offered an order to a bidder at a lower price.

My company pursues a liberal policy in its dealings with manufacturers, and has this year voluntarily granted an increase in prices for high-tension, paper-insulated cables in order that the manufacturers may be assured of a reasonable profit on their product and be able to set aside funds for research, but we do not propose to be coerced into paying higher prices than conditions warrant. David Williams.

1121 Teller Ave.,
New York City.

## *Maintenance of Transformers and Circuit Breakers at Industrial Plants*

*To the Editor of* Electrical World:

In an editorial in the Feb. 18, 1928, issue of the Electrical World you asked the question "Who should take care of the maintenance of transformers and circuit breakers at the plants of industrial customers?" In hundreds of small industrial plants that are electrically operated this problem more often than not remains unsolved, but comparatively little trouble is caused, on the whole, mainly owing to the remarkable reliability of the type of electrical equipment usually installed in such plants. In several cases where I have installed such equipment I have made an effort to get the power company to adopt some schedule for maintenance of the apparatus, arranging for the customer to pay the cost. In cases where the plant is large enough to maintain its own electrical staff this of course has not been necessary. The power company has frequently agreed, has never accepted the responsibility, but has awaited the call of the customer, who knows little or nothing as to the amount of maintenance necessary. In fairness it must be said that some power companies, although they are far too much in the minority, adopt a really constructive attitude and maintain the equipment not only in theory but in practice.

For the last few years circuit breakers with higher interrupting capacities have been installed and the trend in protection equipment has been toward overcurrent relays with battery-operated, direct-current trip coils. Such equipment can maintain its operating superiority only through proper maintenance. The writer's interest lies mainly in the fact that equipment which has been specified and installed may appear to the owner to be unsatisfactory even though its failure was due to improper maintenance.

You say in your editorial that it is a duty of the electric light and power company to maintain such apparatus and you further add that it takes but little persuasion to convince the customer that the power company should do the job. In this you are absolutely right, and when it can also be said that such maintenance work can be performed at no cost to the power company, but actually can be made to yield a fair and legitimate profit, the industry is missing an opportunity to capitalize on service reliability through proper maintenance of apparatus. May I not suggest that power companies following some such plan write of their experiences for the benefit of and as a guide to other companies to make such a practice more widespread. Engineer.

New York, N. Y.

[The author has submitted sufficient reasons for withholding his identity to justify our complying with his request.—Editor.]

# Digest of Electrical Literature

## *Hydro-Electric Development and Steam Equipment*

*Tests of a 12,000-kw. Zoelly Steam Turbine.*—Investigation of the operating characteristics of a Zoelly steam turbine operating under a pressure of 285 lb. per square inch and a temperature of 662 deg. F. at 3,000 r.p.m. was undertaken recently. The machine comprises ten simple impulse wheels with diameters ranging from 51 to 69 in. Results indicate a minimum steam consumption of 9.6 lb. per kilowatt-hour.—*Engineer* (*England*), Feb. 17, 1928.

## *Transmission, Substations and Distribution*

*The Transmission of Alternating Current.*—W. B. Woodhouse.—The adoption of the four-phase system for alternating-current transmission as a means of reducing the number of wires necessary for balanced protection, with other incidental but important advantages, is offered by the author. Comparative figures for two overhead lines bearing equal loads with equal efficiencies, one of four-phase construction and the other a three-phase, six-wire line, offer some interesting information regarding the mechanical properties of the conductors necessary to carry the load. A reduction of 18.5 per cent in the total mechanical loading of the line is indicated with four-phase design and it is stated that this will result in a proportionately greater reduction of the cost of the support and that the transmission line as a whole will be substantially cheapened on both accounts. The author concludes that the facility with which a three-phase system can be transformed into a four-phase system is such that four-phase high-pressure transmission may be combined with a three-phase generation and three-phase distribution without difficulty or undue complication, and the system of transmission may therefore be considered separately.—*Electrical Review* (*England*), Feb. 17, 1928.

*Calculating Sag of Wires for Unequally High Suspension Points.*—G. Schmidt.—The methods generally used for the calculation of mechanical tension and sag in wires when stretched out between equally high supports are only approximately correct. Mathematical proof is given for this statement, and the problem is further developed to be applicable to unequally high supporting points, resorting to catenary or chain-line equations. The influence of exact calculation does not become apparent until actual examples are computed. It is of great value for the safety of the line to determine the exact but unequal stresses in the lower and upper support, to have full assurance that they stay within safe limits. Many methods and tabulations, which have been published lately, including supposedly authoritative ones for the calculation of wire sags, are stated to require corrections to give exact values.—*Elektrotechnische Zeitchrift*, Feb. 9, 1928.

*Cable Conductor Losses.*—C. G. Watson.—The author has devised a method for readily estimating conductor losses taking into account the maximum demand charge as well as the unit charge. On this basis one part of the total value of the loss will be the loss of the system peak multiplied by the cost per kilowatt of maximum demand, but as the maximum load of a cable does not always coincide with the system peak and as it is convenient to use the maximum current as a basis for calculation a correction factor is needed. This factor is said to be the square of the ratio between the current in the cable at the time of the system peak and the maximum current. Illustrative examples tend to prove the contention of the author in connection with the ideas developed in the formulas and charts.—*Electrical Review* (*England*), Feb. 24, 1928.

*Graphic Calculation of Reactors.*—O. Gramisch.—The design of air-core, current-limiting reactance coils can be largely reduced to a simple graphical method by means of alignment charts given in this article. Such charts have been constructed for the size of the (copper) conductor, for the heating under short circuit, for the dimensions of the coil, and for the inductance. The practical solution of the problem of a given reactor for certain inductance, current and time values is not definite. Several designs must be laid out to find the most economical type. This procedure is illustrated by the actual design of a reactor for a 1,000-kva. transformer, using alternately formulas and alignment charts.—*Elektrotechnik und Maschinenbau*, Jan. 29, 1928.

## *Units, Measurements and Instruments*

*Construction of Great Falls-Winnipeg 110-Kv. Transmission Line.*—J. C. D. Taylor.—The problems involved in the distribution of material for the construction of this 70-mile transmission line through two distinct types of country are considered by the author in the first of a series of articles. The details of the organization for the distribution of men and material has received particular attention. An unusual feature of the work was involved in the construction of a 12-mile narrow gage track for the transportation of materials and consisting of 6-in. trees bolted to road ties for use in connection with grooved wheel cars. The motive power was furnished by horses. The character of the ground was such that this was the most economical and desirable way of accomplishing the transport of line materials.—*Electrical News* (*Canada*), March 1, 1928.

## *Motors and Control*

*Phenomena Under a Carbon Commutator Brush.*—H. Lutz.—It is a known fact that the ohmic resistance between a carbon brush and commutator is larger when the machine is running than when it is standing still. Unavoidable irregularities on the surface of the commutator and the carbon particles continually ground off cause the brushes to be more or less in motion at all times. The size of these fine particles of carbon varies between $10^{-3}$ to $10^{-6}$ mm. or about 100 to 1,000 times the size of a carbon atom. Ionization and free electrons will occur under the brush. Contact between brush and commutator will only be point-contact, so that voltage drop will only depend upon the current and not the current density. Several small brushes or one wide brush with undercuts will give a better performance, according to the author, since there are more contact points. Reference is made in the paper to many previously published statements, which apparently agree with the author's recent experimental findings.—*Elektrotechnik und Maschinenbau*, Jan. 29, 1928.

*Developments in Electric Pumping.*—Blake R. Vanleer.—A general review of the subject of pumping has been made in connection with a discussion of the recently developed deep well turbine pump. The author has reviewed the advantages and service requirements which have led to the use of this type of equipment and has emphasized design and test features. A deep well turbine pump, while relatively inefficient, offers unusual features in that the motors may be mounted at the ground level, while the runners are attached to the shaft operating within the well at such intervals as may be desirable.—*Electrical West*, March 1, 1928.

*Fifteen-Ton Electro-Hydraulic Ingot Casting Crane.*—This crane comprises a motor-driven traveling carriage from the center of which rises a vertical pivot which acts as a fixed ram of a hydraulic center. This cylinder, which surrounds the ram, carries the main portion of the crane. The body of the crane has thus both a vertical and circular motion around the central pivot. It consists structurally of two main girders secured to the hydraulic cylinder surrounding the pivot by four sloping ties of steel plate. The operation of this equipment involves the control of six motors, namely, two motors for traveling, one for each of the duties of raising the crane, turning it, reversing the ladle and tipping it. The two traveling motors are controlled by an automatic contactor, which assures a steadily progressive start without reference to the manipulation of the starting handle. The latter, having to deal only with very small currents, is easily moved. The lifting controller is operated by a lever and the connections are so made that the load follows the movement of the hand of the operator. —*Engineer* (*England*), March 2, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*Very High Direct-Current Voltages.* —Erwin Marx.—For general testing purposes, the production of cathode and X-rays, dust precipitation, cable tests and many other research investigations very high sustained direct-current voltages are required. The author shows how, with relatively low potential transformers, a many times higher direct-current voltage can be easily obtained, with the aid of suitable vacuum rectifying tubes and high-voltage condenser batteries. A small 100-kv. transformer can thus readily produce 600 kv. direct-current to ground. In fact, the potential multiplication can be carried readily to a factor of 10, making it possible to obtain 1,000,000 volts direct-current from a 100-kv. testing transformer.—*Elektrotechnische Zeitschrift*, Feb. 9, 1928.

*Some Principles Governing the Choice and Utilization of Permanent-Magnet Steels.*—Raymond L. Sanford. The addition of substantial percentages of cobalt to the composition of permanent-magnet steels leads to markedly superior qualities. The cost of cobalt steels may be several times that of the older types, however, and their use is warranted only under certain circumstances. Criteria for the comparison of the quality of magnet steels are discussed, and the conditions under which the use of the more expensive steels are justified are outlined. Cobalt steels are superior in quality to tungsten and chromium steels, but this superiority can only be utilized by means of appropriate designs. The mere substitution to cobalt steel without change in design will usually lead to disappointing results. Magnets can be stabilized against permanent deterioriation from transient demagnetizing fields by partial demagnetization. The cobalt steels can be stabilized by this method to a greater degree than the steels having lower values of coercive force.—No. 567, *Scientific Papers of the Bureau of Standards.*

*High-Voltage Reactors.*—L. Kropff. —In the discussion of general requirements of current-limiting reactors, some simple formulas are given to calculate size and number of turns required for any given condition. It is shown that the customary design, which is fully satisfactory for up to 6,000 volts, cannot be used economically for much higher voltages, since the mere lengthening of the creepage distances would lead to impossible dimensions. For use in feeder circuits of 30 kv. or more a new design for reactors has proved very satisfactory. Double section disk coils, porcelain spacers and the decidedly novel use of porcelain tension bolts with ball socket ferrules are the outstanding features of this new design. To eliminate static charges on the metallic clamping pieces, they are connected electrically to the ends of the winding. The conductor is made of ribbon copper, insulated with mica, which insures against dust troubles or winding "shorts" due to foreign metal parts. Reactors of this design will safely withstand a testing voltage of four times rated voltage.—*Siemens Zeitschrift*, January, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*Fatigue Studies of Telephone Cable Sheath Alloys*—John R. Townsend.— A discussion of mechanical and metallographical characteristics of fatigue failure of telephone cable sheath and the development of machines to duplicate service conditions. The correlation between the characteristics of service failures and laboratory failures is stressed. The special precautions necessary to carry out fatigue tests on soft metals is outlined. Fatigue failure of lead and the lead antimony alloys covered by this paper is by intergranular failure, and in the case of the lead antimony alloys repeated stress appears to reduce the solid solubility of antimony in lead, producing a widened grain boundary as viewed under the microscope. The type of fatigue test described is sensitive to very slight changes in composition and heat treatment for a particular class of material.—*Reprint B-285 Bell Telephone Laboratories.*

*Generator for Audio Currents of Adjustable Frequency with Piezo-Electric Stabilization.*—August Hund.—A beat-frequency generator for producing audio currents which are practically sinusoidal is described by the author. The frequency is adjustable and stabilized by means of a piezo-electric quartz disk and can be directly read off on a scale. The piezo-electric control makes it possible to reset the calibration for the frequency, for almost any B voltage on the tubes producing the two high-frequency currents which beat with each other. The resetting can be carried on without any standard by means of the filament rheostat common to both oscillator tubes. The slow visible vibrations on the meter for the anode current of the piezo-electric oscillator are utilized for the resetting of the scale. A thermostatic control is provided for very accurate work. Two filter detector circuits are described for obtaining audio currents of a good wave shape and keeping any high-frequency currents away from the load branch. A specially designed power amplifier is also mentioned.—*No. 569, Scientific Papers of the Bureau of Standards.*

## *Traction*

*New Railway Car Lighting System.* —L. Dreyfus.—All hitherto known systems for electric lighting of railway cars provided with axle-driven generator and storage battery require a complex regulating apparatus to keep the lamp voltage constant at widely varying train speeds. The author has developed a new system, in which the generator is of such design that it makes any external or additional voltage regulator unnecessary. This has been accomplished by a machine with a double field and three pairs of small, fixed brushes on the commutator. An 18-volt, 9 amp.-hour auxiliary battery (fourteen alkaline cells) maintains the excitation field essential for the operation of this generator. The arrangement of the two counteracting fields and their connection to the six brushes is such as to maintain a practically constant potential of 24 volts on the lamp circuit and a 30 per cent higher voltage for the charging of the main alkaline car battery. The control panel contains only an automatic double-throw switch for "standstill" and "travel," a combined voltage and over-voltage relay, both of exceedingly simple and robust design, and four adjusting resistors. The generator is positively driven by bevel gears.—*Elektrotechnik und Maschinenbau,* Feb. 5, 1928.

## *Miscellaneous*

*Waste Heat Recovery.*—A discussion of steam generation by waste heat. No reference is made to regenerative processes, air heating or similar expedients, the discussion being limited to certain definite aspects of steam generation by waste heat. The author states that despite economic factors there still appears to be some hesitation in the general adoption of waste heat boiler plants and that the reasons may be summarized as follows: Incomplete knowledge of the exact scope of waste heat recovery, particularly of its influence on fuel consumption and its general effect on the primary process; a tendency to lay too much stress on the troubles met with in pioneer plants installed before the principles governing the subject were properly understood; the practice in certain quarters of overstressing the possibilities of the generation; engineers responsible for the design and operation of furnaces, retort settings, internal combustion engines, etc., have confused waste heat with wasted heat, the latter being a potential reflection on their products. Considerations are largely devoted to steel plants, carbonizing processes and marine engines.—*Engineering (England)*, Feb. 24, 1928.

# News of the Industry

## Tennessee Tax Illegal

*Commission's Imposition of One Mill per Kilowatt-Hour on Power Generated in Hydro Plants Upset by State Court, Along with Recapture Clause*

HOLDING that although the Tennessee Eastern Electric Company must apply to the Railroad and Public Utilities Commission of that state for a certificate of convenience and necessity before proceeding with hydro-electric developments on the Holston River, none the less the commission's attempt to impose a tax or rental of one mill per kilowatt-hour of generated electricity on the output of hydro-electric companies is unconstitutional, the Chancery Court at Nashville handed down last week an opinion of far-reaching importance to the power industry of Tennessee and other states.

The court held that the Legislature has not conferred the taxing power upon the utilities commission; that the commission is not legally empowered to require the applicant for a certificate of convenience and necessity to agree to surrender its property at the end of 50 years under terms to be set out in such certificate; that the water-power value of the company's property must be included in the rate base, not on the basis of the cost at the time of acquisition, but on the basis of the present or existing value at the time the rate is to be fixed, and that the commission cannot exercise jurisdiction over the assignment, transference or alienation of the certificates of convenience and necessity to the exclusion of court authority.

Though in other matters the commission was upheld in its general jurisdiction over the power company and its right to issue certificates, require public hearings, fix rates, and generally oversee the development and distribution of power, the opinion is obviously a victory for the complainant power company, as the imposition of the one-mill tax or rental, the recapture clause and the jurisdiction claimed over assignments of the certificates were the sections of the commission's order from which the complainant was seeking relief.

## Radio Bill Becomes a Law

After weeks of uncertainty and delay in Congress, President Coolidge on Wednesday signed the radio bill, passed by the Senate on March 24, after previous acceptance by the House, and it became law, effective at once. In addition to the provision extending for a year the life of the Federal Radio Commission as a control body and the clause providing for "equal" distribution of radio service to the five zones and "equitable" distribution among the states within the respective zones in accordance with population, the bill provides that broadcasting licenses shall be issued for not to exceed three months, instead of three years as at present, and other classes of licenses for not longer than one year, instead of five as under the existing law. Indications are that the new law will materially curtail the number of licenses and the power enjoyed by big radio centers like New York and Chicago. Unused wave lengths, time or station power can, however, be allocated elsewhere than to the zone originally entitled to them. The new license provisions are to terminate Jan. 1, 1930.

## Elihu Thomson Attains His Seventy-fifth Birthday

THURSDAY of this week was the seventy-fifth birthday of Elihu Thomson, consulting engineer for the General Electric Company at its Lynn works. Dr. Thomson passed the anniversary quietly with his family at his home in Swampscott, Mass., but many letters and telegrams of congratulation reached him. Among the numerous honors that have been bestowed upon him in the course of his career have been the presidency of the American Institute of Electrical Engineers, the Grand Prix award, the Rumford, Edison, Elliott Cresson, John Fritz, Hughes, Kelvin and Franklin medals of American and foreign societies, and honorary membership in the National Electric Light Association. A special resolution in honor of Dr. Thomson was passed by the association's executive committee at a session on Thursday.

## New Permits Granted by Federal Power Board

*One for White River, Ark.—License for St. Croix Falls, Wis.—Applications for Sites on Roanoke, Flint and Salt Rivers*

A PRELIMINARY permit for the White River Power Company of Little Rock, Ark., was authorized at a meeting of the Federal Power Commission held March 26. The company's plan provides for the construction near Cotter of a storage dam 226 ft. high. Other dams and power houses below Cotter, on the White River and on its Buffalo and North Forks, are planned. It is estimated that 70,000 hp. of primary power will be made available. It is planned to install 165,000 hp. A conflicting application by the Ozarks Hydro-Electric Company was withdrawn recently.

The application of the Western Washington Electric Light & Power Company for a preliminary permit on North River in Washington also was authorized. It is planned to install 40,000 hp.

A license was authorized for the St. Croix Falls Improvement Company covering a project on the St. Croix River in Wisconsin. It is proposed to install 66,500 hp. at Kettle River Rapids and at Nevere.

A license was granted to the Citizens' Light, Power & Water Company covering a constructed project on Ketchikan Creek in Alaska. The plant has an installation of 2,500 hp. A preliminary permit covering a proposed development on Ward Cove Creek, near Ketchikan, Alaska, was also authorized. The applicants are H. G. McCain and five others, all of Ketchikan.

The permit covering the project of Julian H. DeCoster of Idaho Falls and Steve Meikle of Victor, Idaho, on Palisade Creek was authorized. The applicants are required to determine the feasibility of storing water in the upper and lower Palisade lakes. It is planned to install 9,000 hp.

The Bunker Hill & Sullivan Mining & Concentrating Company was authorized to construct a 350-hp. project on Deadwood River, Idaho.

As no additional water rights are likely to be granted soon on Seepe and Piru Creeks by the California authorities, the commission rescinded its action in authorizing a preliminary permit for the Ventura Power Corporation.

The Roanoke River Power Company of Richmond, Va., has applied to the Federal Power Commission for a license covering a project on Roanoke River near Buggs Island. It is proposed to construct a dam 80 ft. high to create a reservoir with 240,000 acre-feet capacity. The reservoir would extend upstream for 23 miles. It is planned to install 70,200 hp. and to construct a transmission line to connect with the system of the Appalachian Power Company. The primary capacity of the project is 8,900 hp.

J. J. Williams, O. M. Heard, W. E. Grubbs, P. F. Fitzgibbons and Dr. J. A. Ward of Cordele, Ga., have applied for a license covering a project on Flint River. It is proposed to install four units of 3,600 hp. each. The license, if issued, is to be transferred to Crisp County. The power is for public use.

John L. Fish of Lakeside, Ariz., has applied for a license covering a project on Salt River, Gila County, Ariz. It is proposed to install 24,000 hp. capacity.

The Southern Sierras Power Company, of Riverside, Calif., has applied for a license covering a transmission line 13 miles long over public lands in San Bernardino County. The Western States Gas & Electric Company of San Francisco has applied for a license covering a transmission line from Camino to the tramway of the Michigan-California Lumber Company.

The City of Sand Point, Idaho, has applied for a preliminary permit covering a site on Priest River, in Bonner County, Idaho. It is proposed to construct four dams and power houses with an installed capacity of 10,000 hp.

# House Committee Reports Its Shoals Bill

## New Measure Differs Only Slightly from the Norris Bill Adopted by Senate, and Final Agreement Is Now Predicted—Leatherwood on Boulder Dam Bill

BY A VOTE of seventeen to four, the House military affairs committee on Wednesday, March 28, ordered a favorable report on a bill for government operation of Muscle Shoals which is so closely in agreement with the principle of the Norris resolution, already adopted by the Senate, that, if it is passed by the House, there is little doubt that differences between the two measures can be ironed out easily, thus assuring legislation at this session. The House committee bill, fathered by Representative Morin, the chairman, sets up a government corporation to be administered by a bipartisan commission of five members appointed by the President to operate Muscle Shoals, producing fertilizer and selling surplus power, instead of leaving operations to the Secretaries of War and Agriculture, as the Norris bill did. This is the principal difference. The government corporation to be set up will be capitalized at $10,000,000. Fertilizer manufactured is to be distributed equally among the states, territories and possessions.

Indications point clearly to passage of the committee bill by the House. The same influences which actuated the Senate majority in adopting the Norris resolution are being felt in the House—the promise of cheaper fertilizer for the farmers in an election year, the fact that no private offer for Muscle Shoals remains before Congress and utter weariness with the entire subject. These are sufficient, it is confidently believed, to overcome any opposition to government operation as a principle. Furthermore it is believed President Coolidge will sign a government operation bill to dispose of Muscle Shoals if one is presented to him.

The bill reported out by the House committee Wednesday was to be formally reported to the House before the end of the week. With that accomplished, the chairman had been instructed to inform the rules committee that a rule to give the bill privileged status for action is sought. If this is granted, as is held certain, the bill probably will be voted upon in the House within the next four weeks.

Before voting upon the government operation bill, the House committee Wednesday took from the table for reconsideration the Madden bill embodying the bid of the American Cyanamid Company, which measure has been vigorously advocated by the American Farm Bureau Federation. A new recapture clause offered Monday in a letter to the committee was incorporated in the bill, but the measure, thus revised, was voted down by twelve to five, four members not voting. The Norris resolution was taken from the table and the committee bill was substituted for everything after the enacting clause.

It has not been decided whether the minority in the committee will submit a dissenting report to the House advocating substitution of the Madden bill. Representative Hill of Alabama, who voted against the committee bill, expressed his conviction that the appropriation of $10,000,000 in wholly insufficient, that the bill does not mean cheap fertilizer for the farmers, and that far from taking the matter out of the hands of Congress and assuring continuous operations at Muscle Shoals, it means that Congress must be consulted virtually every year and asked for additional money, which may or may not be given.

### Leatherwood on Boulder Dam

An extensive minority report on the Boulder Dam bill has been submitted by Representative Leatherwood of Utah, who sums up his arguments as follows:

> It proposes a serious invasion of state sovereignty in turning the Colorado River over to the federal bureaucracy. It accomplishes nothing immediately but the assurance of prolonged litigation between the states and the federal government. It is not a flood control project but a power project, wherein flood control is delayed indefinitely and subordinated to power development. It creates and invites international complications with the Republic of Mexico. Congress is asked to authorize at once the risking of the taxpayers' funds in an engineering experiment in the face of warnings that the project has had insufficient engineering studies and should be reviewed by the country's ablest engineers. It inaugurates a new socialistic principle in government expenditure—that the government may enter business whenever there is a promise that by so doing it may make a government undertaking 'self-supporting and financially solvent.' In this instance all known facts point to almost certain loss on the government's venture into business. Aside from flood control, the needs upon which the project is supposed to be based—more water for irrigation and domestic use in California, a market eager for power, improvement of navigation—are largely non-existent or can be just as well served by any other dam on the Colorado River. I find that not a single one of the major representations as to the project is true; that it has been promoted by political methods and not on its merits.

The bill authorizing the Federal Power Commission to employ its own personnel was rejected in the House by the close vote of 179 to 168. It is known that the Senate committee favors the bill and that it has a chance to pass the Senate. An effort probably will be made to attach the measure to some other legislation, with the possibility that it may be brought before the House again this session for another vote. The principal argument advanced against the measure was that it would make possible the building up of a new bureau.

## New York-Paris Telephone Is Inaugurated

Transoceanic telephone communication between the United States and Europe was extended on Wednesday to France, conversation between New York and Paris being carried on with complete success. Sending and receiving circuits were connected with a loud speaker, and four hundred employees of the American Telephone & Telegraph Company in that company's assembly room heard the speeches made by President W. S. Gifford at the New York end and Maurice Bokanowski, French Minister of Commerce and Industry, at Paris.

## Rate-Base Pleas Delay Work, Says Bay State Board

Declaring that the contentions of many companies on behalf of the reproduction-cost rate base retard its work, the Massachusetts Department of Public Utilities submitted a report to the Legislature on March 21 replying to inquiries of the House as to the rate-regulating situation in the state and set forth that ample authority exists to enable the commission to regulate rates within the time available. Between April 26, 1926, and March 15 last the board has held 445 public hearings, made 563 orders and findings and four special reports.

In answer to an inquiry as to the advisability of establishing a zone system of rates in the territory of the Boston Edison Company, the commission stated that evidence taken by it in recent cases puts it in a position to bring about the establishment of such rates if it deems them just. The statute giving the board the right to initiate rate inquires has aided the commission's power of suggestion to companies whose rates appear to it to be open to reduction. The report points out that voluntary reductions have either been made by a number of leading companies or that cases are pending on the board's docket for their consideration.

## Aftermath of the Disaster at Los Angeles

*One of the Generators Left Standing on Site of Plant No. 2 May Be Salvaged—How the Edison Company's 220-Kv. Vincent Line Proved Its Worth*

INVESTIGATION into the condition of the two 17,500-kw. General Electric turbines which were the only parts of Los Angeles' municipal plant No. 2 left after the waters let loose by the failure of the St. Francis Dam had receded indicates that one of them will probably be salvaged but that the other is in very bad shape and the possibility of repair is doubtful. No plans for rebuilding plant No. 2 have yet been announced, and it is said that should work begin immediately, it would require at least a year to complete it. Engineering testimony so far elicited points to the unstable character of the rock forming the foundation of St. Francis Dam as the cause of the disaster.

Information which was received just too late for last week's news recounts that after the flood had left the mouth of San Francisquito Canyon, headed for the ocean, it crossed the two 220-kv. Big Creek lines of the Edison company. Nine towers were torn down in the west line. This line was repaired and in operation by 5 p.m. March 16, three days after the flood. The East Big Creek line, immediately adjacent to the west line, had three towers destroyed. This line was put back into operation March 19. The third, or Vincent, 220-kv. line was not affected. To provide for just such emergencies as existed during and after this flood this third line had been built by the Edison company over a new right-of-way entirely separate from the original two lines. When the original two lines went out the hydro load was immediately transferred to the Vincent line.

The Saugus switching station of the Southern California Edison Company at the mouth of San Francisquito Canyon was put out of commission temporarily. Service to Santa Barbara and Ventura Counties was interrupted when this switching station went off the line. The Edison company had 300 men on the ground before daybreak Tuesday morning, March 13, and had built a temporary line around the Saugus switching station to serve these two counties before business opened up in these communities.

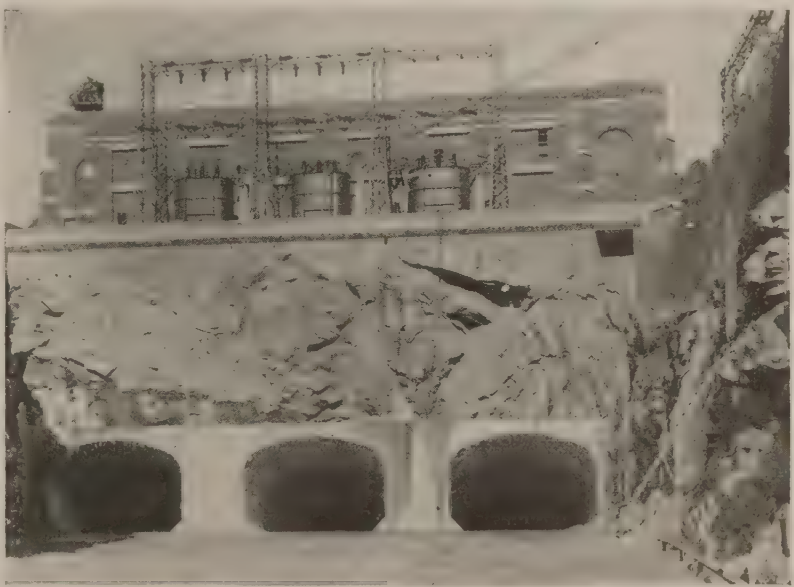
On a mesa immediately adjacent to the bed of the Santa Clara River, down which stream the floodwaters raged, the Edison company had a construction camp of 178 men. This camp was about 22 miles away from the St. Francis Dam. The floodwaters covered this tableland and destroyed the camp. Of the 178 men in the camp, 42 have been found dead and 42 were still missing when this account was prepared. Ninety-four escaped alive. C. W. English lost his life and B. D. Haugh suffered a broken leg and serious internal injuries when the airplane in which they were flying to reconnoiter the affected area crashed on a mountain peak in the vicinity of St. Francis Dam. These men were both connected with the operating department of the Edison company.

A resolution of the Board of Water and Power Commissioners of Los Angeles expressing its sympathy for the loss of life by employees of the Southern California Edison Company and expressing "appreciation and gratitude" to the company was made March 14. The Edison company's monetary loss will not exceed $100,000. That of city bureau property is now put at $5,000,000.

## Floods in Sacramento Valley Do No Serious Harm

Heavy seasonal rains in central and northern California lasting from March 22 to 26 brought flood conditions to many Sacramento Valley points and caused the Pacific Gas & Electric Company and the Great Western Power Company some inconvenience. All storage reservoirs are spilling heavily, but no damage of any consequence to structures other than canals and flumes has been reported. One small power plant belonging to the Pacific Gas & Electric Company had three feet of water over the power-house floor, but little damage was done to the generator and other equipment. Some of the reclaimed areas in the Sacramento Valley are flooded, but service interruptions of the two power companies have been local and only minor in character. Ability of the companies to maintain power service to drainage pumps was the means of saving crops on many thousands of acres of reclaimed land in valley regions.

## Bellows Falls (Vt.) Hydro Plant on Line



THE new 60,000-hp. hydro-electric station of the New England Power Association on the Connecticut River at Bellows Falls, Vt., was phased into the system on March 27. The development includes a generating plant with three 20,000-hp. vertical single-runner Francis-type waterwheels, each directly connected to a 17,000-kva., three-phase, 60-cycle generator. The project required raising the old dam and providing additional spillway and canal facilities, as well as the construction of a new power house. The dam is of the gravity-section concrete type, 620 ft. long, with two bays equipped with roller gates, each with a height of 18 ft. The canal is 1,700 ft. long. The operating head is 60 ft.

Energy is generated at 6,600 volts and stepped up to 66 kv. and 110 kv. for transmission. Connections operated at 44,000 volts feed north into New Hampshire and Vermont, connecting with the system of the Vermont Hydro-Electric Corporation at Charlestown, N. H. The 66-kv. substation ties south in Vermont to Putney and Vernon. From the 110-kv. substation a 60-mile, double-circuit steel-tower line on private right-of-way delivers energy to an important switching station at Pratt's Junction, Mass., from which point 66-kv. lines radiate to load centers in New Hampshire, Massachusetts and Rhode Island.

Work was begun in May, 1926, the New England Power Construction Company acting as engineer and the Sherman Power Construction Company, Worcester, Mass., as contractor.

# Purchases and Mergers

*Atlantic Public Utilities Changes Hands —New Insull Company Organized— Dothan, Ala., Will Sell Plant for $2,000,000—Many Small Transactions*

CHASE & GILBERT, Boston, have acquired the Atlantic Public Utilities from Charles W. Young & Sons of Boston and will manage these properties henceforth. Besides water companies, the group includes the Provincetown (Mass.) Light & Power Company, Indiana Light & Power Company, General Utilities Company, Ohio Northern Public Service Company, Shenandoah River Power Company, Brookville (Ind.) Electric Company and the Colby Light & Power Company of New Sweden, Me.

The Illinois Commerce Committee has before it the application of the Super-Power Company of Illinois to organize a fourteen-million-dollar electrical power corporation to function with Insull interests. The petition discloses plans to purchase the property of the Powerton Electric Generating Company, involving affiliation with the Commonwealth Edison, Illinois Power & Light, Public Service of Northern Illinois and Central Illinois Public Service companies.

Consolidation of nine public utility companies in Missouri, Kansas, Nebraska, Oklahoma and Alabama into the Central States Edison Company was announced on March 28. Electric light and power companies included are Gasconade Power Company, Hermann, Mo.; the North Kansas Power & Light Company, the Beatrice (Neb.) Power Company, the Gulf Utilities Company and the Foley (Ala.) Light & Power Company.

Dothan, Ala., whose municipal power system has had various vicissitudes, voted recently by 1,174 to 671 to authorize the City Council to sell the municipal electric and water properties for $2,000,000. No offers were pending. The Alabama Power Company was not a bidder at that price. In June of last year the city voted by 710 to 672 against selling the electric plant to the Gulf Electric Company, a subsidiary of the Alabama Power.

Barton, Vt., has agreed to purchase the one-man power plant owned and operated in that town for 20 years by Dr. E. M. Nichols for $117,000. The Public Utilities Corporation had offered a better price for the plant without success. Voters decided to operate it as a municipal property and will issue bonds to cover the purchase price. Dr. Nichols bought the property in 1908, when it had 30 customers, for $2,800. It now has 103 miles of transmission lines.

A certificate has been filed at Albany under which the New York State Electric Corporation merges the Georgetown Electric Lighting Company.

According to Fred L. Santway of Theresa, N. Y., president of the Hydro-Electric Power Company, approximately $75,000 will be spent there this summer in development work to combine the Hydro-Electric, the Snell and the Makepeace Power companies, which will then be sold to the St. Lawrence Utilities Company.

Alleged attempts by undetermined interests to obtain options on the property of twelve independent electric utilities on the Eastern Shore of Maryland, with the promise of lower rates through the transmission of energy from the Conowingo Dam, are being investigated by the Public Service Commission of Maryland. The communities concerned are Cecilton, Millington, Betterton, Chestertown, Church Hill, Centerville, Queenstown, Easton, Oxford, Trappe, St. Michaels and Claiborne.

The Southern Ohio Electric Company of Athens, Ohio, has petitioned the Public Utilities Commission for permission to buy the Hocking Power Company of Nelsonville for $530,826 and the Mutual Electric Company of Pomeroy for $65,455.

By a special election in Emmetsburg, Iowa, the Municipal Utilities Company of Des Moines has been authorized, by a vote of 941 to 366, to install and operate an electric plant to cost $147,000. The Des Moines concern, which is in effect a financing corporation, agrees to turn the plant over to the municipality when earnings have paid for the original cost and maintenance. The Iowa Public Service Company unsuccessfully sought a franchise in Emmetsburg.

The citizens at Ashby, Minn., cast an almost unanimous vote in favor of selling the Ashby lighting plant to the Otter Tail Power Company.

The Central Public Service Corporation has bought the electric distribution system of the Worcester Lumber Company at Chassell, Mich. This purchase is for the Houghton County Electric Light Company.

Purchase by the Dakota Public Service Company from the Northern Utilities Corporation of the electric property at Cleveland, N. D., has been approved, as has the purchase by M. A. Erickson of Rugby of electric properties at Souris and Westhope from Victor Frykman and the Condit & Son Electric Company respectively.

The village of Lushton has sold its distribution system to the Iowa-Nebraska Light & Power Company, from which it has been buying wholesale. The company will reduce lighting rates and offer a new service for range and refrigeration.

Approval of the Kansas Public Service Commission has been granted for the sale of the municipal electric light and power plant at Coldwater to the Western Light & Power Corporation, Salina. Sale of the Natoma (Kan.) municipal distribution system to the Kansas Power Company, Topeka, has been agreed upon by the City Council. The city will retain title to the power-house property. Negotiations have been completed for the sale to the Kansas Utilities Company, Fort Scott, of the municipal plant and distribution system of Toronto, Kan. Buildings are not included.

Citizens of Atwood, Kan., have voted to sell to the Central Kansas Power Company, with headquarters at Hays, the city's electric plant and distribution system.

The electric plants at West Union and Salem, West Va., have been sold by the Mountain State Utilities Corporation to the Monongahela-West Penn Public Service Company of Fairmont.

Rio Grande City, Falfurrias, La Pryor, Palacios, Waelder and Flatonia are listed by the Central Power & Light Company as the Texas towns where existing properties were acquired by it in 1927.

The electric light and other utilities at Caddo, Tex., have been sold to S. R. Morgan of Little Rock, Ark., for $75,000.

Option on the sale of the Kellogg (Idaho) Power & Water Company for $250,000 to an unnamed Eastern syndicate was announced by President J. S. Ramage at Spokane, Wash., recently. A distribution system at Kellogg, in the Idaho Panhandle mining district, and a small generating station are involved.

A holding company to be known as the Stevens County Public Service Corporation is being organized at Spokane, Wash., to hold the common stock of the Stevens County Power & Light Company, A. H. Sperry, president of both, announces.

Sale of the Capitola Company, supplying energy to Capitola, Calif., to the Public Utilities California Corporation, a W. B. Foshay company, has been sanctioned by the California Railroad Commission.

Application has been made to the California Railroad Commission by the Pacific Gas & Electric Company for permission to merge the properties of the El Dorado Power Company, the Western States Gas & Electric Company and the Coast Valleys Gas & Electric Company with its system and for the acquired utilities to abandon public utility service. Control of these companies was purchased from the Byllesby interests by Pacific Gas in May, 1927.

Fifteen Pennsylvania power companies, all owned by the Potomac Edison Company, with headquarters at Hagerstown, Md., have been consolidated. The new company, which includes the Waynesboro Electric Company and fourteen township companies in Franklin, Fulton, Adams and Bedford Counties, will be known as the South Pennsylvania Power Company and will continue to be controlled by the Potomac Edison.

## Great Western Is to Purchase Feather River Company

The Great Western Power Company of California has applied to the Railroad Commission for authority to take over control of the Feather River Power Company, whose Bucks Creek plant on the Feather River is scheduled for completion by July 1. The application provides that a controlling stock interest in the Feather River Power Company is to be purchased by the Western Power Corporation of New York but shall be conveyed at the original purchase price to the Great Western Power Company of California on or before the expiration of two years.

The properties of the Feather River Power Company are valued at approximately $9,000,000 and consist of the Bucks Creek hydro-electric development with a 55,000-hp. plant which will utilize water from a 110,000-acre-ft. storage reservoir under a head of 2,561 ft. At the time the Bucks Creek development was started the Great Western Power Company contracted to purchase the entire output of the plant for a period of 35 years, at the expiration of which period the plant was to become the property of the Great Western.

## Connecticut Light & Power Adds to Hartford Office

Effective tomorrow, April 1, the engineering, merchandise sales and advertising staffs of the Connecticut Light & Power Company, as differentiated from the company's operating organizations, will move from Waterbury to 36 Pearl Street, Hartford, which has for some time been the headquarters of the president, treasurer and general financial interests of this utility and the Connecticut Electric Service Company.

## Rocky Mountain Men Sponsor Underground-Stream Survey

With a view to enhancing the value of agricultural resources and at the same time developing a substantial power load, the electric utility companies of Colorado, New Mexico and Wyoming will undertake a survey of the underground streams in their territory. This ambitious movement was launched at a joint conference of the Colorado Utilities Association and the Rocky Mountain Division of the National Electric Light Association held at Colorado Springs on March 19 and 20. While the public utilities are sponsoring the project and will largely direct it, the actual work of making the survey will be undertaken by the Colorado State Agricultural College under the supervision of President Charles A. Lory. The utility men of the Rocky Mountain States believe that this project will give a great impetus to rural-line extension and development and create heavy pumping load in at least a dozen localities.

Utility men from half a dozen Western states attended the meeting, and every phase of their industries received attention. Meetings were conducted by various chairmen, who used questionnaires, to which those in attendance responded with expressions of their views and experiences. Engineering commercial surveys, the value of national association committee research, local committee work, the tendency away from hydro-electric to steam-electric generating, overhead systems, inductive co-ordination, meters, underground systems, high-pressure turbines and the use of powdered-coal fuel were the engineering topics. V. L. Board, Public Service Company of Colorado, led the discussion of public relations, followed by H. S. Sands, who spoke on co-operation with educational institutions, and George H. Shaw. Meetings of the Commercial and Accounting Sections were also held, under G. B. Buck and Harry Adler, respective chairmen.

## Minnesota Governor Opposes Backus Plans for Border

Governor Theodore Christianson of Minnesota has joined in the opposition to the construction of a series of dams on the Minnesota-Ontario border as proposed by E. W. Backus of the Backus-Brooks Company, Minneapolis. The Governor, in a letter to the secretary of the state Izaak Walton league, declares: "I do not favor the exploitation of publicly owned water and lands of this region for hydro-electric purposes by any private interests."

A state survey of Minnesota's power potentialities on the basis of which legislation fully protecting the public's rights should be drawn is advocated by State Auditor Ray P. Chase. With engineering facts as a basis, the state should then set about to determine what waters could be best utilized for industrial or power purposes and which should be retained in their primeval conditions for recreational purposes, he said, adding:

"It has been the history of Minnesota that in some instances applications for authority to construct dams have not been filed until after the dams were constructed and the power plants in operation. Of what avail is it to talk of public rights after those rights are gone? The Federal Power Commission requires that any applicant company comply with all of the state's laws before an application is granted. The commission declares that it does not claim and never has claimed authority to dispose of the use and ownership of public waters, but thus far it has been unable to find any statute of Minnesota requiring the consent of the state as a condition precedent to the construction of dams impounding the waters of the streams of this state."

## Maryland Utility Men Meet in Baltimore

In addressing the members of the Maryland Utilities Association at the sixth annual convention, held in Baltimore, March 23, and referring to the federal investigation, Governor Albert C. Ritchie of Maryland stated that he perceived no indication that the utilities of the country were trying to take advantage of the public. Public ownership of the securities of these companies, and hence of the companies, was, he said, the greatest safeguard of the public interests. The relation between the utilities that want to serve and those whom they desire to serve was seen by the Governor as constantly improving.

The electric light and power, gas, water and transportation groups met separately in the morning session and jointly in the afternoon. Following the committee reports on meters and rural development, Earl Whitehorne, commercial editor of the ELECTRICAL WORLD, outlined the economic and promotional factors involved in the present inadequate development of the national domestic consumption of electrical energy. L. S. Storrs, managing director American Electric Railway Association; Major Alexander Forward, managing director American Gas Association, and Major H. S. Bennion, director of engineering, National Electric Light Association, referred to some of the problems confronting their respective industries. Major Bennion stressed the fallacies entertained by those uninformed on interconnection, with particular reference to the economic inadvisability of power transmission over great distances, and gave figures showing the limited amount of power involved in interstate transmission.

President H. B. Potter presided. The officers elected for the coming year are: President, H. T. Connolly, Washington, Baltimore & Annapolis Electric Railroad Company; vice-president, H. A. Brooks, Potomac Electric Power Company; treasurer, R. E. Towne, Potomac Edison Company; secretary, David Kinneau, United Railways & Electric Company.

## Ontario Premier Tells of the Hydro's Problems

In a discussion on hydro-electric estimates in the Ontario Legislature recently Premier Ferguson forecast the complete utilization of Ontario's water-power resources within a few years. Even allowing for a possible increase of 500,000 hp. on the Ottawa River should the questions now before the Supreme Court be decided in favor of the province, a possible 1,000,000 hp. from the St. Lawrence development and a possible 500,000 hp. from additional diversions at Niagara Falls which might be arranged by international treaty, the Premier thought that, with the power consumption of the province increasing each year by 100,000 hp., it would not be long until all available power would be utilized. "There is delay over which we have no control in connection with the St. Lawrence development," said the Premier. "It is now four years since we filed at Ottawa our plans for power development." He had asked Premier King for the report made to the Ottawa government by the National Advisory Council, but, as the matter had an international aspect, Mr. King had declined to make the report public.

Experiments were being made, according to Mr. Ferguson, with what he called a "booster system." Should these work out successfully, the Hydro system might, the Premier thought, be able to transport power with comparatively small loss from sources in northern Ontario which are wholly within the control of the province. Otherwise it would have to depend on the boundary sources owned jointly with Quebec or with the United States.

A vote of $1,250,000 for transmission and distribution lines on the Ottawa system was passed, as was one of $350,000 for transformer stations. A great increase in the load being carried on the Georgian Bay system, particularly between Waubaushene and Midland, and 62 miles of rural extension on that system accounted for a vote of $75,000 for that district. Approximately one million dollars will be spent on the Niagara system this year.

## Ontario Hydro Statistics Put Before Legislature

Provincial Treasurer J. D. Monteith told the Ontario Legislature the other day that the total horsepower in use by the Ontario Hydro-Electric Power Commission was now 1,600,000, with another million available. The Hydro paid into the treasury in 1927 for interest $7,848,043, Mr. Monteith said. The commission fulfilled its undertaking in regard to debt retirement, making a payment of $1,338,567, which represented its share of the $3,000,000 required on this account. "The finances of the Hydro are today in a very strong position," the Minister declared. "It has met all its obligations and even widened its usefulness by annual expansion."

The total available undeveloped power

in the province was estimated at 5,000,000 hp. The number of miles of transmission lines is 7,066. In 1927 807 miles of rural transmission lines were constructed, and the government contributed $1,100,000 in rural bonuses on this account. The entire debt of the province at the end of the fiscal year 1927 was $147,485,906, and the number of homes served by the Hydro-Electric Power Commission was 420,000.

## Work for Utilities by Commission Men Criticised

Governor F. R. Zimmerman of Wisconsin has sent a letter to the Wisconsin Railroad Commission condemning the practice of permitting employees of that body to work for public utility companies. He even suggests that all commission employees be requested to sign contracts that they will not upon leaving the commission enter public utility employment for a period of one year. The Governor's letter was prompted by a report made to the Legislature by the Railroad Commission in which the latter listed a large number of employees who were doing outside work for the public utilities and also listed a number of commission employees who later were permanently employed by public utility companies.

## Peek Tells of His Researches Into Lightning Phenomena

Tests with artificial lightning on small models in the Pittsfield, (Mass.) laboratory of the General Electric Company reveal that there is always a protected cone about a tall building or lightning rod, F. W. Peek, Jr., consulting engineer of the company in charge of high-voltage investigations, declared at New York on March 22 in a talk before members of the American Institute of Electrical Engineers. The radius of this protected area extends from the base of the building a distance of two to four times the height of the building, depending upon the altitude of the storm cloud. The chance of another building in this protected area being struck depends upon whether or not it extends above an imaginary line drawn from the top of the taller building to the edge of the protected area, Mr. Peek said. How these laboratory experiments were borne out in a natural electrical storm over New York last August when the New York World building was struck was described.

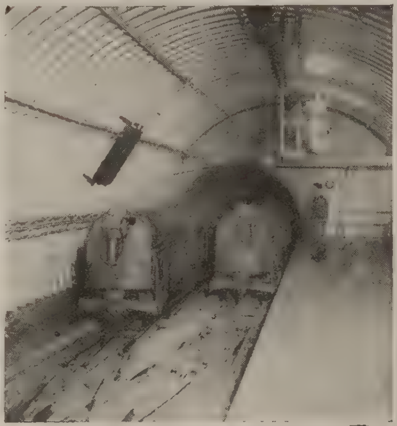
These laboratory experiments have progressed so successfully, according to Mr. Peek, that the protected-area plan has already been adopted in the safeguarding of oil-storage tanks in southern California. Several tall rods, placed near the outside of the big oil reservoirs, provide overlapping protected areas and thus greatly reduce the hazard of conflagrations from lightning flashes.

Another point touched on by Mr. Peek was that a cathode-ray oscillograph had been constructed in the laboratory by which lightning has been made to "write its autobiography" with a pencil of electrons on a photographic film. The lightning flash not only records itself but sets the device in operation, causing it to work automatically and at the correct time, although the flash may last but a few millionths of a second.

## Briefer News

**New High-Tension Line Under Way for Washington Water Power Company.**—A 110-kv., 40-mile transmission line is being built by the Washington Water Power Company from its Long Lake power station to the East Side substation at Spokane. The line is of two-pole construction and will give increased capacity from the power station to Spokane and the Cœur d'Alene mining district of northern Idaho.

**London Has Miniature Mail-Tube Railway.**—In a tube railway recently built by the General Post Office of London, England, trains carrying mail run without a driver between Mount Pleasant, Whitechapel and Paddington at the rate of 35 miles an hour. The trains are operated by electricity from a control room in the Post Office. It is the first tube system of its kind.



© Henry Miller Service.

**Highway Authorities and Transmission Lines.**—The right of highway authorities to supervise construction of power transmission lines on public roads is at issue in Iowa, where a permanent injunction has been obtained in Kossuth County to prevent the Central States Electric Company from erecting a line not in accordance with specifications made by the county engineer. Similar suits are pending in Pocahontas and Greene Counties.

**Chats Falls (Quebec) Hydro Plant to Start with 30,000 Hp.**—Plans have been announced for the development of the Quebec side of Chats Falls, on the Ottawa River, one of the few remaining major power sites in the Ottawa district. Plans of the Chats Falls Power Company, as filed with the Quebec government, call for an initial development of 30,000 hp. in two 15,000-hp. units. The site has a potential development of about 90,000 hp. It is also probable that High Falls, on the Lievre River, also in the Ottawa district, will be developed in the near future. The power rights at this site are owned by the Maclaren Lumber Company of Buckingham, Quebec.

**Oklahoma Gas & Electric Company Dedicates New Office Building.**—On Saturday, March 24, the new office building of the Oklahoma Gas & Electric Company at Oklahoma City was thrown open to inspection by the public, who thronged its offices, salesrooms and auditorium. The building, at Main and Harvey Streets, is of steel and stone and rises six stories. It is so designed that an additional six stories can be added in accordance with the architect's plan illustrated in the Electrical World for March 19, 1927 (page 623.)

**Electricity Brings Prosperity to North Carolina Mines.**—Completion by the Carolina Power & Light Company of a 47-mile, 60,000-volt transmission line from Asheville to Spruce Pine, N. C., at a cost put at more than half a million dollars, has, local reports say, brought a boom to the mining community reached, which had previously only about 75 kw. connected. In three months many mining industries have doubled their capacity and new industries have gone in.

**American Committee for Tokyo Conference Organized.**—Engineering leaders from many parts of the United States met at Washington on March 22 and formulated preliminary plans for participation in the World Engineering Congress which will be held next year in Tokyo. Officers elected for the American committee were: Honorary chairman, Herbert Hoover; chairman, Elmer A. Sperry; vice-chairman and chairman of the executive committee, John W. Lieb; vice-chairmen, C. E. Grunsky and C. E. Kettering; executive secretary, Maurice Holland. The Japanese Ambassador, Tsuneo Matsudarja, and Dr. Sperry addressed the engineers at a dinner following the meeting.

**Miller Rubber Company at Akron Now Completely Electrified.**—Installation of a new cooling plant for the Miller Rubber Company, Akron, Ohio, has been carried out by the Northern Ohio Power & Light Company. In addition, the company's engineers have supervised the entire electrification of the Miller factories, which cover 35 acres of ground. A substation of six 2,000-kw. transformers, with necessary switching equipment, has been erected and two 750-kw. synchronous motor-generator sets have been installed. An outdoor switching and transformer substation receives 22,000-volt, three-phase, 60-cycle power from the utility company, which is stepped down to 2,200 volts. The Miller plant now consumes electrical energy at the estimated rate of approximately 32,190,000 kw.-hr. annually.

Transmission Line Will Cross Big Muddy in Single Span.—The Central Illinois Public Service Company's 33,000-volt transmission line has been completed from the West Frankfort substation to Royalton, as far west as Freeman Junction, and from Royalton to the edge of Big Muddy River. The Big Muddy will be crossed at this point by a 1,015-ft. span. The 11,000-volt transmission line to Louisville has been completed, as has also the Teutopolis-Montrose 11,000-volt line.

Northwest Accounting Section Meets at Portland.—Committee reports, a thought-provoking discussion of published financial statements and the presentation by L. J. Pierce of a different conception of public relations and the accountant's responsibility therein than has prevailed were the principal features of the meeting of the Accounting Section, Northwest Electric Light and Power Association, at Portland, Ore., on March 12. F. W. Brownell, chairman of the section, outlined a broadened scope of activity.

Michigan Companies Establish Farm Electrification Research Fellowship. — Substantial recognition of the progress that Michigan State College is making in adapting electric power to the work of farms in the state has come in the form of an offer from the Detroit Edison Company and the Consumers Power Company of a fund for the establishment of a farm electrification research fellowship. With this offer came the tender of a second fund for the equipping and operating of a farm electrification demonstration truck to be sent out through the state this coming summer and fall under the direction of the Michigan State College. The fellowship fund is to be $2,000 a year for two years while the truck demonstration fund is $2,500. The fellowship will be awarded to a graduate engineer —preferably to an agricultural engineer.

Ultimate Production of 170,000 Hp. on Roanoke River Prophesied.—Ultimate development on the Roanoke River in Virginia of approximately 170,000 hp. is a prophecy based on the announcement that the Roanoke River Power Company of Richmond has applied to the Federal Power Commission for permission to construct a dam and power station on the Roanoke that will develop 70,200 hp., with transmission lines tied in with those of the Appalachian Power Company. The proposed power plant, at Buggs Island, is a few miles above the upper power site owned by the Virginia Electric & Power Company. The latter owns four power sites on the Roanoke, only one of which, at Roanoke Rapids, N. C., is developed. The three others are below the site of the Roanoke River Power Company's proposed plant, and it is thought that at least one of them may be developed by the Virginia Electric in the next two or three years. The Roanoke Rapids plant furnishes about 8,000 hp., and the three undeveloped sites are thought to be capable of producing 30,000 hp. each. Thus when all the Virginia Electric & Power Company's sites are developed that company will have available from the river nearly 100,000 hp., which, added to the Roanoke company's 70,000 hp., gives the top figure hoped for.

## *Coming Meetings*

[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]

Southwestern Division, N. E. L. A.—Edgewater Gulf Hotel, Biloxi, Miss., April 3-5. S. J. Ballinger, San Antonio Public Service Company, San Antonio, Tex.

Nebraska Section, N. E. L. A.—Omaha, April 4 and 5. T. A. Browne, 1527 Sharpe Bldg., Lincoln.

Southeastern Division, N. E. L. A.—Miami, Fla., April 11-14. C. M. Kilian, 207 Bona Allen Bldg., Atlanta.

American Institute of Electrical Engineers — Baltimore regional meeting, April 17-19; New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities—Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Arizona Utilities Association—Prescott, Ariz., April 26-28.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

Eastern Association of Electrical Inspectors Has New Officers.—A recent election by ballot for officers of the Eastern Association of Electrical Inspectors resulted as follows: President, C. S. Cahaskie, New York; first vice-president, W. C. Field, Springfield, Mass.; second vice-president, J. P. Rohan, Hartford, Conn.; third vice-president, R. M. Nesbitt, Philadelphia; treasurer, A. W. Hopkins, Springfield. The new secretary is R. Walker, 16 Court Street, Brooklyn. The association voted by a large majority to unite in the formation of an international association.

Montana Power Company's New Dams.—Completion of the dam and power plant of the Montana Power Company at Black Eagle Falls of the Missouri River is noted in the company's just issued 1927 report. The cost was $1,680,000, 10 per cent under the estimate. This plant utilizes to its full capacity under existing circumstances the first of the series of three falls of the Missouri River near the city of Great Falls and is the company's sixth development on the Missouri. The dam at the outlet of Mystic Lake was also completed, raising the level of the lake 20 ft., increasing the storage and permitting the use of the generating facilities there at full capacity during a longer period of each year.

Arkansas Power & Light Completes Maguire Substation. — The Cullendale substation of the Arkansas Power & Light Company, recently completed at a cost of a half million dollars, has been named Maguire substation as a tribute to the late W. C. Maguire, who was a member of the Arkansas Power & Light Company organization for many years. It is situated 3 miles south of Camden and contains four 1,667-kva. transformers, stepping down the voltage from 110,000 to 33,000. The station is operated by remote control. With the transmission lines from the Louisiana line and the rebuilding of the 66,000-volt line from Pine Bluff to carry 110,000 volts, an investment by the utility company of about $750,000 is represented.

Hearing Given on Cooper's Clark's Fork Hydro Plans.—Application for the development of 265,600 hp. at "Z" canyon, on the Clark's Fork branch of the Columbia River in northeastern Washington, has been heard at Newport, Wash., by Major John S. Butler of Seattle, representing the Federal Power Commission. The cost is estimated at $17,600,000. No conflict arose in the testimony of county officials, the Columbia Basin project officials and local residents. The Pend Oreille Lead & Zinc Company, however, claimed prior right in behalf of its proposed development of a site at Metaline Falls, just above the "Z" canyon site. The mining company's site would be flooded by Cooper's development. (See ELECTRICAL WORLD, March 3, page 474.)

GREAT NORTHERN POWER COMPANY WILL START FIRST UNIT IN APRIL.—The project of the Great Northern Power Company, which hopes ultimately to develop 160,000 hp. on streams in Snohomish County, Wash., and wants to serve the city of Seattle until the Skagit plant is able to carry all the load, is going ahead, according to the president of the company, J. E. Wickstrom. A 1,200-hp. unit at Gold Bar is to go into service in April, with 40 per cent of the output already contracted for. A primary rate of 2 cents for the first 5,000 kw.-hr., with a large-power rate of $22 a horsepower, is predicted when the new development gets under way. The company will go into new territory, Mr. Wickstrom says, and not compete either with the city of Seattle or the Puget Sound Power & Light Company.

SASKATCHEWAN GOVERNMENT AIMS AT PUBLIC OWNERSHIP.—Through legislation to be introduced at the present session of the Provincial Legislature the Saskatchewan government will seek authority to construct and operate central electric power plants, erect high-tension transmission lines and transformers, expropriate existing power plants and transmission lines and other equipment at its replacement value and sell energy, electrical appliances and equipment to urban and rural dwellers. George Spence, Minister of Railways, Labor and Industries, made this announcement, which met with general support in the Legislature. In the meantime the Montreal Engineering Company is going ahead with the construction of more than 300 miles of transmission lines in the province this year. In the neighboring Province of Alberta another 500 miles of line will be built.

NEW ST. LOUIS STREET-LIGHTING CONTRACT GOES TO WESTINGHOUSE.—A contract amounting to $2,250,000, said to be the largest single award ever made for a street-lighting improvement, has been made with the Westinghouse Manufacturing & Electric Company by the city of St. Louis. The contract is the fourth to be awarded in connection with the city's eight-million-dollar street-lighting project, and the area to be lighted includes the downtown district as well as a number of thoroughfares intersecting the city. The Westinghouse company will furnish the equipment, which will include 4,500 hollow-spun granite standards of special design with a height on the major thoroughfares of 24 ft. and supporting twin lighting units. Single-light standards having a height of 18 ft. or of 13 ft. will be installed on the streets which carry lighter traffic. The installation must be completed on Dec. 8.

# Commission Rulings

CONDITIONS MODIFYING OBLIGATION OF COMPANY TO EXTEND SERVICE.—Setting up two principles—first, that an electric utility should extend its lines to render service within the territory which the company undertakes to serve if the extension can be made without placing any undue burden on the company's other patrons; second, that it should not be required to make a comparatively large investment necessary for service to a group of new patrons without some assurance of reasonably adequate revenue for a definite length of time—the Maine Public Utilities Commission ordered the Central Maine Power Company to extend a 2,300-volt line about 6 miles to serve complainants living in a fairly prosperous and well-settled community within the company's territory, on condition that an adequate gross annual revenue fixed by the commission be guaranteed for five years. Subject to the payment of this guaranty, rates were to be in accordance with the company's published schedule.

PRINCIPLES GOVERNING APPROVAL OF CONSOLIDATIONS.—In granting authority to the Central Maine Power Company to absorb the Bethel Light Company, the Black Stream Electric Company, the Fryeburg Electric Light Company and the Western Maine Power Company, the Maine Public Utilities Commission reiterated a former statement of the considerations which govern it in passing upon such applications. These are: (1) the legal right of the purchaser of the new corporation or utility to acquire and hold the property affected by the consolidation; (2) the probable effect of the consolidation with reference to service in the territory affected; (3) the probable consequences of the sale, so far as the interest of the public is concerned with reference to rates, and any other particulars by which the public might be affected, including: (a) petitioner's capacity to serve its present territory, (b) to meet its obligations to present security holders, (c) improvement of service, diminution of cost of management and operation.

COOKING RATE MUST NOT BE EXTENDED TO OTHER USES BY MEANS OF RANGE OUTLETS.—The North Dakota Board of Railroad Commissioners has ordered discontinued the practice of the Otter Tail Power Company at Devil's Lake of offering a special rate for stoves having outlets for other electric appliances such as flatirons and washing machines, thus obtaining the low cooking rate for energy used by these. The decision resulted from the protest of a steam laundry and other consumers that they were paying far more for power than domestic consumers paid for electricity for cooking and other uses. The cooking rate was shown to be 4 cents per kilowatt-hour, while the power rate paid by the protestants began at 7.77 cents, grading downward. A low rate for cooking to develop business was held by the commission to be a sound practice. It was further held, however, that "the consumers of Devil's Lake and other cities who have purchased and operate electric ranges upon representations by the utilities that they could attach all appliances and obtain preferential rates have been made parties to a practice which we believe results in discrimination." The commission added: "We respectfully direct the attention of the electric utilities to this recommendation and request their earnest consideration with a view to voluntarily taking action. Should the desired result remain unaccomplished, we shall have no alternative but to investigate upon our own motion." A solution suggested by the board but not incorporated in its order was that three separate rates be substituted for the cooking rate now in use. The first would be the present cooking rate and would apply to stoves having no outlets to which appliances could be attached; the second would be a rate for electric stoves with such outlets and would cover energy used for such appliances as well as for cooking; the third would be a combination lighting and cooking rate and would apply to all energy used in the household. It was specified that the rate for the second class of service should compare favorably with the power rate.

# Recent Court Decisions

POLICE POWER OF STATE UPHELD IN OKLAHOMA.—The Oklahoma Supreme Court, in Galbreath vs. Oklahoma Natural Gas Company, has sustained the power of the commission to modify as to rates the terms of a contract or franchise made by a municipality with a public utility. The suit was filed originally on behalf of the city of Tulsa and various citizens, but the city and all except three of the individual complainants withdrew. The plaintiffs sought recovery of large sums of money which it was alleged had been collected from Tulsa citizens in violation of the contract with the company after the commission had authorized an increase in the rate. The Supreme Court, quoting the state constitution, said: "The Corporation Commission has power to regulate the charges for public services by municipal corporations. Such power is inherent in the state and is a necessary attribute of sovereignty."

INSTRUCTION IN DAMAGE SUIT REQUIRING PLAINTIFF TO PROVE ABSENCE OF CONTRIBUTORY NEGLIGENCE HELD ERROR.—Declaring that in federal courts the burden of proving contributory negligence is on defendant, whether or not the trial is held in a state holding that the burden is on plaintiff, and that an instruction in the trial court requiring plaintiff to prove the absence of such negligence by the preponderance of evidence was erroneous, the United States Circuit Court of Appeals in West Virginia reversed a verdict for the defendant in Dunagan vs. Appalachian Power Company, a suit asking damages for the death of a man who had charge of an electric fan in a stable and endeavored to stop a leakage of electricity by pulling a switch on a pole outdoors. Evidence showing that after the accident the company grounded a fence which was supposed to have produced a short circuit through the victim's body was properly excluded, the federal court held; but an instruction to the effect that the defendant was not negligent if the lines were properly constructed and equipped was erroneous in ignoring the duty of inspection. (23 F. [2d] 395.)*

# News About Men of the Industry

## *G. C. Ward Named Executive Vice-President*

George C. Ward, vice-president in charge of engineering and construction for the Southern California Edison Company, was made executive vice-president at the recent annual meeting of the board of directors. Though born and educated in the East, Mr. Ward's chief engineering achievements have been tied in with the development of the great hydro-electric potentialities of California, his adopted state. Since 1912, when the Big Creek-San Joaquin River project of the Southern California Edison Company was first conceived, he has been actively interested in the work and his guiding hand has been apparent from the very beginning. His outstanding accomplishment in connection with this enormous task was the successful completion of the 13-mile Florence Lake tunnel through the solid granite of the Sierras. In recognition of his endeavors he was presented with a bronze medallion by the United States Chamber of Commerce in December, 1925.

*G. C. Ward*

Mr. Ward was born in White Plains, N. Y., and after being graduated from Phillips Andover Academy he engaged in railroad location and survey work for the Raquette Lake Railroad in New York State. Until 1906 he was continuously connected with railroad and bridge building and it was during this period that he became associated with Collis P. Huntington and Henry E. Huntington. It was at the instigation of Henry E. that he transferred his interests to California. When the Pacific Light & Power Corporation, of which he was vice-president, was consolidated with the Southern California Edison Company Mr. Ward became vice-president.

---

Selby Summers has resigned his position with the distribution engineering department of the Utica (N. Y.) Gas & Electric Company to enter the engineering department of the New York Power & Light Corporation at Schenectady.

Samuel Insull, Jr., has been elected a director of the Commonwealth Edison Company, Chicago, to fill the vacancy caused by the recent death of Watson F. Blair.

T. S. Sloan, formerly connected with the Central Georgia Power Company, Macon, has resigned to become division manager of the Georgia Power Company at Rome.

Hon. Mayland Morse, formerly Assistant Attorney-General of New Hampshire, has been appointed a member of the Public Service Commission of that state.

Owen D. Young, chairman of the board of directors of the General Electric Company, sailed for Europe March 24 abroad the French liner *Paris* for his annual pleasure trip abroad. Most of his visit will be spent in England.

Lawrence Palk, formerly assistant to the president and secretary of the Winnipeg Electric Company, Winnipeg, Man., has been appointed assistant general manager in charge of executive matters. Mr. Palk will continue in the capacity of secretary.

Herbert Southworth has been appointed superintendent of the Bristol County (R. I.) Gas & Electric Company, succeeding Abel Reynolds, who recently became general manager and treasurer of the New England Water, Light & Power Associates. Mr. Southworth was formerly employed by the New England Telephone & Telegraph Company at Providence, and since 1923 has been an engineer in the power sales department of the Narragansett Electric Lighting Company of that city.

Prof. H. B. Walker, head of the department of agricultural engineering at Kansas State Agricultural College, Manhattan, and since 1910 a member of the faculty of that institution, has resigned to accept a similar position with the agricultural branch of the University of California at Davis. He will leave Kansas June 1. Professor Walker has taken a most active interest in the work of the Kansas Committee on Relation of Electricity to Agriculture since its formation, serving as secretary and treasurer from the time the committee was organized. With the establishment of the rural electrical laboratory, embracing nine electrified farms near Larned, Kan., Professor Walker was also made state supervisor of the committee. Active in many projects involving a mutuality of interest between power companies and agricultural leaders, Professor Walker has come to be well known to the public utility industry of the Middle West.

## *William Baurhyte Resigns*

William Baurhyte, president of the Los Angeles Gas & Electric Corporation for the past four years, has resigned, effective March 31. Mr. Baurhyte's retirement as chief executive of the Los Angeles utility brings to a close an association which covered a period of 25 years. Starting in the office of second vice-president, he retained that position until 1913, when he assumed the duties of vice-president. Mr. Baurhyte's valuable services won the recognition of the company's officials and in 1921 he was named vice-president and general manager. When the office of president became vacant through the retirement of W. B. Cline, in the spring of 1924, Mr. Baurhyte was the logical selection for a successor. Mr. Baurhyte was also a member of the board of directors. Addison B. Day, executive vice-president and general manager, has been named president.

*William Baurhyte*

---

J. H. Henderson, who served as commerce counsel of the Iowa Railroad Commission from 1911 to 1927, when he was succeeded by Dwight N. Lewis, has been reappointed to that position. Mr. Lewis recently resigned.

Robert B. Grove, assistant secretary of the United Electric Light & Power Company, New York, since 1925, has been elected secretary to succeed the late William J. Meyers. Mr. Grove has been identified with the United organization since 1907 and has served successfully as draftsman, general assistant in the engineering department, assistant to the electrical engineer, assistant to the vice-president and general manager and assistant secretary. When he was made assistant secretary, in 1925, he retained his former title and duties as assistant to the vice-president and general manager, in which capacity he still serves. Mr. Grove has always been an ardent worker for the National Electric Light Association, at the present time being vice-chairman of the Accounting National Section, secretary of the lamp committee, assistant traffic manager and a member of the industrial relations committee.

Edgar L. Hartpence has been elected vice-president of the Acme Wire Company, New Haven, Conn., to succeed Leonard S. Taylor. Mr. Hartpence also succeeds Victor M. Tyler as general manager. Mr. Tyler, however, continues as president of the company.

George F. Mitchell, treasurer of the Midland Utilities Company, Chicago, since its formation, five years ago, was elected a vice-president at a meeting of the board of directors, and William A. Sauer, comptroller during that period, has also been elected to a vice-presidency. Both these new executives have also been elected to the board of directors.

E. Ogden Ketting, formerly assistant secretary of the Commonwealth Edison Company and for several years secretary to Samuel Insull, president, has left for England to become joint managing director of Insull, Son & Company, Ltd., of London. He has also been elected a vice-president of Insull, Son & Company, Inc., of Chicago and New York.

Kinsey M. Robinson, engineer for the Payette division of the Idaho Power Company, has been appointed manager of that division to succeed J. D. Orr, who has been transferred to the Twin Falls division. Mr. Robinson has been identified with the Idaho Power Company and its predecessor, the Idaho-Oregon Light & Power Company, since 1911.

L. B. Harvey has been elected president of the Porcelain Insulator Corporation, Lima, N. Y., succeeding his father, W. F. Harvey, whose death was announced in these columns several months ago. Mr. Harvey is a graduate of Georgetown University and since leaving college has spent the greater part of his time with the Porcelain Insulator Corporation in various capacities.

John L. Burns, formerly assistant to president of the United Gas Improvement Company, Philadelphia, has been promoted to the position of manager of the insurance and personnel department of the company. Mr. Burns became identified with the United Gas Improvement Company in 1926, when Arthur W. Thompson was named president of that utility. Previously he had been associated with Mr. Thompson for twenty years in public utility work.

C. H. Spiehler, mechanical engineer of the Columbia Engineering & Management Corporation for the past year and a half, is now in charge of the engineering staff for the electrical properties of that corporation with headquarters in Cincinnati. Following graduation from the Massachusetts Institute of Technology in 1908, Mr. Spiehler joined the Rochester Railway & Light Company in the capacity of heating engineer. Two years later he removed to Dayton, Ohio, where he became affiliated with the Dayton Power & Light Company, at first as heating engineer, subsequently as mechanical engineer and then as superintendent of power stations. He entered the employ of the Columbia Engineering & Management Corporation in August, 1926.

## *O. J. Shaw Resigns*

O. J. Shaw has resigned as vice-president of the Iowa-Nebraska Light & Power Company to devote his time to private interests. He is president of the Lincoln Oil Company and Lincoln Insulating Company. He will retain offices in the headquarters building at Lincoln and will remain in an advisory capacity with the company.

*O. J. Shaw*

Mr. Shaw has been connected with Lincoln public utilities for the past eighteen years, starting as head of the electric lighting department of the Lincoln Traction Company. Subsequently he became assistant secretary and later was placed in charge of the overhead distribution system, power plant operation and steam heating system. Then he was made secretary and in 1919 general manager, the position he occupied when the United Light & Power interests took over the property. Following the consolidation of the Lincoln Traction with the Lincoln Gas & Electric Mr. Shaw became general manager of the Lincoln Public Service Company, predecessor of the Iowa-Nebraska Light & Power Company. Previous to his experience in Lincoln Mr. Shaw was manager of plants at Aurora and Harvard. He graduated from the electrical engineering department of the University of Nebraska in 1907.

Edward L. Gay has been appointed manager of the Keene district of the Public Service Company of New Hampshire, succeeding the late Ralph D. Smith. Mr. Gay is a native of Keene and has been in the employ of the Keene district company most of his business life. He entered the service as a bookkeeper, in time becoming assistant treasurer, and later devoting his time to handling the securities of the Public Service Company in the Keene district.

## Obituary

James E. Johnson, president of the Canton Electric Light & Power Company, Canton, N. Y., died suddenly March 18 at his winter residence in St. Petersburg, Fla.

George L. Gibson, formerly purchasing agent of the Rutland (Vt.) Railway, Light & Power Company, Clyde River Power Company, Hortonia Power Company and Vermont Hydro-Electric Corporation, died at Rutland March 25 at the age of 54.

Wolcott Remington, vice-president and director of the Thomson Electric Welding Company, Lynn, Mass., died at Lynn March 20 following an illness of a week. He was a graduate of the Massachusetts Institute of Technology. Mr. Remington was cited by the British Government and given a medal of honor for his services in the World War in munitions production.

Gaetano Lanza, engineer, died at his home in Philadelphia March 21 in his 79th year. Dr. Lanza was for 40 years affiliated with the teaching staff of the Massachusetts Institute of Technology, in 1911 having become professor emeritus of mechanics. He was born in Boston and received his education in Virginia. Before his connection with the Massachusetts Institute of Technology Dr. Lanza was assistant instructor at the University of Virginia.

E. W. Cameron, electrical engineer of Buffalo, N. Y., died suddenly March 18 while on a visit to New York. Mr. Cameron was 55 years of age.

William F. M. Goss, formerly dean of the College of Engineering at the University of Illinois and president of the Railway Car Manufacturers' Association for ten years, died March 23 at the Waldorf-Astoria Hotel, New York. Dr. Goss is probably best known to the electrical industry for his work as a member and later as chief engineer of the Chicago Association of Commerce committee on smoke nuisance and the electrification of railroad terminals in Chicago. In the course of his academic career he organized the department of practical mechanics at Purdue University, with which institution he was connected for seventeen years, being dean of the engineering school for a large portion of that time. In 1907 he became dean of the College of Engineering of the University of Illinois, but ten years later he severed his connection with that faculty to take up the duties of president of the Railway Car Manufacturers' Association. Dr. Goss was quite active in association work, having been a president of the American Society of Mechanical Engineers, a fellow of the American Association for the Advancement of Science, a member of the Society for the Promotion of Engineering Education and of other engineering associations. He was a native of Massachusetts and a graduate of the Massachusetts Institute of Technology.

# Financial and Statistical News

### *Price Levels Unchanged Few Discount Bonds*

FEW changes of any importance took place in the prices of power and light common stocks during the week, market interest being centered, for the moment, in more speculative issues. Prices have been firm, however, with the trend upward.

Power and light company bonds have been firm with several price rises. A feature of these issues is the exceedingly large proportion of prices showing a premium. Discount bonds are becoming difficult to find.

### Engineers Public Service Leads New Issues

During the past week the Engineers Public Service Company issued 320,000 shares of $5 dividend convertible preferred stock at $100 per share to yield 5 per cent. Proceeds will be applied with other funds toward the retirement of the entire outstanding 311,662 shares of $7 dividend preferred stock at $110 per share and accrued dividends. This refinancing plan will effect a reduction in annual preferred dividend requirements of $581,634.

Gold debentures of the Iowa Public Service Company were offered at 95 and accrued interest, to yield about 5.30 per cent, a piece of financing involving a total of $1,500,000.

The United Public Utilities Company issued 35,000 shares of $6 dividend series preferred stock at $94.50 per share and accrued dividends, yielding about 6.35 per cent.

The North Continent Utilities Corporation made an offering of first lien and refunding gold bonds, series A, totaling $3,500,000, the price being 97 and interest, to yield about 5.75 per cent.

One foreign issue appeared during the week, the million-and-a-half-dollar loan floated by the Municipal Gas & Electric Corporation of Recklinghausen, Germany. The offering was in the form of first mortgage twenty-year sinking fund 7 per cent gold bonds.

DUQUESNE LIGHT STOCKHOLDERS APPROVE CHANGES IN SET-UP.—Stockholders of the Duquesne Light Company approved the changes in capitalization outlined in the Jan. 21 issue of the ELECTRICAL WORLD. They voted to change the authorized common stock from 250,000 shares (par $100) to 1,000,000 shares of no par value. At the same time they increased the number of shares to 4,000,000. There was also approved an issue of 5 per cent cumulative first preferred stock amounting to $50,000,000.

### *Critical Investor Buys Utility Stocks*

ONE of the largest and most critical institutional investors in America—the Sun Life Assurance Company of Canada, with assets of more than $400,000,000—evidently has few misgivings about the standing of American public utility company securities. In its list of holdings appear common stocks of such companies as Commonwealth Edison, Consolidated Gas of New York, Detroit Edison and Public Service of New Jersey, totaling $21,299,903. The same list shows $20,573,445 of preferred stocks, the great bulk of which are of United States utilities. Its utility bond holdings total $27,114,464, of which at least $17,000,000 are bonds of public utilities in the United States.

## January Revenue Establishes New Peak

### Energy Output for Electric Light and Power Companies Close to 6,700,000,000 Kw.-Hr.—Revenue $172,400,000, Increase of 3.9 per Cent Over December Earnings

A CONTINUOUS upward trend is reflected in reports of operations of electric light and power companies for January. The energy output, 6,699,748,000 kw.-hr., was nearly as great as in December, notwithstanding the seasonal decrease in the lighting load. The operating revenue rose to $172,400,000, computed for 100 per cent of the industry by including estimates for missing reports. This is 3.9 per cent in excess of the earnings for December and thus establishes a new record. The returns also indicate an increase of 7 per cent compared with January, 1927, which is rather better than the average increase in October, November and December. Operating expenses, exclusive of interest, taxes, depreciation or deductions for sinking funds, amounted to $66,200,000; the increase in this item over January, 1927, was 4.6 per cent and was

*Data on "energy generated" are those collected and published by the United States Geological Survey for all public utilities minus such data as are collected on energy generated by electric railway companies, reclamation service and manufacturing plants. The data are, therefore, for the electric light and power industry only.

†1928 figures are only approximately comparable with those for 1927, because of changes in classification of certain plants.

thus relatively smaller than the increase in operating revenue.

Taking into account the growth of the electric light and power industry, as established by statistics covering a considerable number of years, and taking into account also the cycle of seasonal changes as determined from the monthly figures for the past five years, it is possible to estimate the normal income for each month. As shown on the chart, the actual earnings for January are within 2 per cent of the estimated normal.

The increase of revenue for January, 1928, over that for January, 1927, was not confined to any one region, as is evident from the following table:

| Region | Per Cent Increase |
|---|---|
| New England | 7.3 |
| Atlantic | 6.4 |
| North Central | 6.8 |
| South Central | 7.2 |
| Western | 5.1 |

The regional increases in energy output followed very closely the ratios prevailing in December. The greatest gain was in the West South Central States, where the output was 20 per cent greater than in January of last year. In the South Atlantic States the increase was 15 per cent. In other parts of the country the gains were smaller, running down to 1 per cent in New England. The output in the Mountain States, chiefly from water power, showed a decrease of 3 per cent, while the Coast showed a change from 6 per cent increase in December to 8 per cent in January.

As in December, the output by the use of water power constituted about 39 per cent of the total; 4,108,994,000 kw.-hr. were generated from fuel, requiring the consumption of 3,304,126 tons of coal, 551,756 barrels of fuel oil and 4,893,386,000 cu.ft. of natural gas,

## Associated Gas & Electric Plans Refunding Program

A new 4½ per cent issue of twenty-year debentures of the Associated Gas & Electric Company, amounting to $50,000,000, is being offered directly to the company's security holders, each holder of record March 22 being entitled to subscribe for $20 par of debentures for each share of stock or each $100 principal amount of registered convertible securities held. Proceeds will be used to refund the 5½ per cent and 6 per cent convertible debentures outstanding and in addition to provide funds for the retirement of the preferred stocks of subsidiary companies and for the acquisition of new properties.

## General Electric Earned $6.41 Net on Common

Net profits of the General Electric Company for 1927 increased nearly 5 per cent to $48,799,489, although orders received during the year declined 5 per cent. Orders totaled $309,784,623, against $327,400,207 in 1926. Unfilled orders at the end of 1927 were $68,916,000, against $72,297,000, also a decrease of 5 per cent. Net sales billed during the year were $312,603,772, against $326,974,104. The income accounts for the past two years show total income of $51,547,687, against $49,657,295 in 1926.

Selling prices of the company's prod-

ucts continued downward during 1927 as a result of improved manufacturing methods and keen competition in the industry, according to the annual report just issued.

The balance sheet of the company shows current assets of $252,668,341 and current liabilities of $33,147,449. General reserve was $30,158,263, against $27,696,551 a year previous, and the profit and loss surplus was $115,096,616.

---

COLORADO UTILITY RETIRES PREFERRED.—First steps have been taken toward the retirement of the outstanding 7 per cent preferred stock of the Public Service Company of Colorado with an offer to convert owners' holdings into preferred or common stocks of the Cities Service Company, the parent organization. Public Service stock will be accepted at 110 as payment for Cities Service shares at their market prices. Approximately $6,400,000 of Public Service 7 per cent preferred is now outstanding and it is believed that as soon as the present offer is withdrawn a call will be issued for the unconverted balance. The stock is callable at 110 on 45 days' notice.

# Many Stockholders Added to Public Service of New Jersey

AN INCREASE of 8.1 per cent in gross earnings, against a 12.2 per cent growth the previous year, is disclosed in the annual report of the Public Service Corporation of New Jersey. Net earnings, however, due to an improvement in the operating ratio, are up 11.3 per cent, against 9.4 per cent in 1926. Gross earnings of the system have reached the huge total of $115,005,908, and total assets are $615,460,097.

The corporation reports a very substantial increase in business during the year. Sale of electric current during 1927, exclusive of current furnished the Public Service Railway Company, amounted to 1,233,984,052 kw.-hr., which is an increase of 142,234,480 kw.-hr., or 13.03 per cent. The gain in meters was 77,716, making a total of 781,959 in service at the end of the year. This total exceeds the number of gas meters for the first time. Power sales amounted to 770,756,047 kw.-hr., a gain of 11.36 per cent, while commercial light gained 16.71 per cent and sales for municipal lighting 9.65 per cent. Maximum load amounted to 435,500 kw., against 415,000 kw. in 1926. One of the new contracts is with the Holland tunnels.

Analysis of the Public Service Corporation's earnings statement shows a balance of $9,302,163 earned on common stock. This is the equivalent of $2.30 per share on stock outstanding at the end of the year. A dividend of $2 was paid on common shares.

Capital adjustments during the year include the issue of 576,338 shares of no par common stock, $32,542,100 of 6 per cent cumulative preferred and $3,800 of 7 per cent cumulative preferred stock. Five additional issues of 6 per cent cumulative preferred stock were also authorized. Both these were offered to shareholders and the unsold balance was marketed under the company's popular ownership plan. The corporation purchased during the year 1,975,000 shares of Public Service Electric &

Gas Company and a number of issues of lessor companies.

At the end of 1927 there were 89,769 accounts on the stock ledgers of the corporation, against 67,303, and there were in addition, 18,912 open accounts, indicating an unusually wide distribution of shareholders.

Puget Sound Company Plans Retirement of 7 Per Cent Issue.—At a meeting to be held May 2 stockholders of the Puget Sound Power & Light Company will vote on a proposal to redeem $10,000,000 of 7 per cent prior preferred stock at $110 a share. This will be made possible through the issuance of 110,000 shares of new $5 cumulative no par prior preferred stock. Any required balance will be provided by an additional issue of $6 preferred.

## Southern California Edison Votes Change in Set-Up

Stockholders of the Southern California Edison Company, at their annual meeting, March 16, approved an increase in the company's preferred and a decrease in its common stock. The proposal to issue $5,000,000 par-value common stock to employees at not less than par ($25) was also approved. It was decided to decrease the authorized amount of common stock from $125,000,000 to $100,000,000 and to increase the amount of preferred "C" stock from $20,000,000 to $45,000,000.

Of the 6,345,773 shares of stock outstanding, 4,762,173 shares, or some 74 per cent of the total, were voted at the meeting, either in person or by proxy. Only 500 shares of stock voted against the proposal to change the authorized common and preferred stocks, but 600 shares of stock objected to offering common stock to employees.

British Cable and Radio Companies Merge. — Britain's Eastern Telegraph Company and associated companies and the Marconi Wireless Telegraph Company have jointly announced a provisional fusion in the form of a holding company, provided the companies negotiate an agreement with the British and Dominion Governments and the shareholders approve, cables Commercial Attaché William L. Cooper, London, to the Department of Commerce. The holding company is capitalized at £53,700,000 of 5½ per cent preference and 7½ per cent ordinary shares.

# Business News and Market Conditions

## The Electrical Unions and Armored Cable

Rumors have been circulated in the trade that the electrical workers' unions will not permit the use of armored cable in New York. A committee of manufacturers conferred with H. H. Broach, vice-president of the International Electrical Workers' Union, relative to this, and Mr. Broach recently appeared at the district attorney's office, Bronx County, in response to a subpœna issued because of a complaint against such interference. On both occasions Mr. Broach stated that the unions would not take any action to prevent their members from installing armored cable.

The board of governors of the National Electrical Manufacturers' Association has approved recommendations presented by its labor committee as follows:

1. That you urge all members of Nema not already members of the League for Industrial Rights to take out membership in that organization immediately.
2. That all member companies having trouble with organized labor, in so far as it affects the free distribution of their products, at once notify the labor committee of Nema for such action as may seem best, and that the matter may be brought to the attention of other members of Nema.
3. That our representatives on the executive committee of the National Electric Light Association lay before that committee the facts in reference to existing labor conditions and their effect on the industry.
4. That our representatives on the board of governors of the Society for Electrical Development (which is the co-ordinating organization of the entire electrical industry) lay before that board the facts in regard to existing labor conditions, discussing with such representatives from other branches of the electrical industry the situation in detail and its effects on restricting the development of the entire industry.
5. That representatives on the above organizations report to the board of governors of Nema for action at the next meeting.
6. Your labor committee believes that every right and proper step should be taken by Nema to protect the electrical manufacturing industry in the unrestricted distribution of its goods so that an open and free market may be maintained.

## Activity Slightly Above Last Year

### Production in Electrical Manufacturing Plants Holding Up Well—February Rate of Operations 1.2 Per Cent Over 1927

DURING February the electrical manufacturing plants of the nation reported that productive operations were slightly below those of January, but were slightly above those of February last year. Although the operations of the electrical manufacturing plants during the past few months at times have been under those of the same month in the year previous, yet the volume of production for the twelve-month period ended during the current February was about 1 per cent over that during a similar period ending with February last year. The operations of the larger electrical manufacturing companies appear to be holding up materially better than the smaller companies. The February rate of production of the smaller companies was 12.3 per cent under the peak reached last October, while that of the larger companies was actually 4 per cent above the rate of production reported for last October.

The index of activity in the electrical manufacturing industry based on consumption of electrical energy stands at 121.8 for February, as compared with 124.7 for January and 131.3 for the peak month of October. Comparative indexes of productive activity referred to the average activity for the period 1923-25 as 100 and adjusted for number of working days are as follows:

| | |
|---|---|
| February, 1928 | 121.8 |
| January, 1928 | 124.7 |
| December, 1927 | 125.4 |
| October, 1927 (peak month) | 131.3 |
| February, 1927 | 120.5 |
| February, 1926 | 113.8 |

While past history would indicate that it is perfectly normal for the electrical manufacturing plants to reduce their rate of operations gradually from October to about April, general industry in the nation appears to reach its low point normally in December, the first quarter of the year usually witnessing a material increase in activity. This increase during the current year was slightly below that of the first quarter of 1927, but appears to have exceeded that of both 1925 and 1926. The February operations of general industry were about 16.2 per cent over those of last December.

## Hoist Manufacturers Hold Annual Meeting

At the annual meeting of the Electric Hoist Manufacturers Association, held in New York on March 15, N. A. Hall of the Sprague hoist division, Shepard Electric Crane & Hoist Company, New York, was elected chairman of the association, and H. J. Fuller of the Yale & Towne Manufacturing Company, Stamford, Conn., was elected vice-chairman. The American Engineering Company of Philadelphia and the Chisholm-Moore Manufacturing Company of Cleveland were elected to membership. Reports which were submitted at the meeting indicate that electric hoists are now being used in 95 industries. In addition to the regular statistical work of the association, which includes the gathering of information monthly regarding the number and value of hoists ordered, segregated under standard rating sizes, and value of shipments, there has been inaugurated a plan for the collection of information regarding inquiries for hoist quotations. An effort is being made by the association to determine what relation exists between inquiries and orders.

# Market Conditions

BUYING in New England is being well sustained with a good demand recorded for motors. A number of electric furnace orders are pending final approval. A prominent manufacturer states that New England business has shown a steady growth and, with the exception of 1920, sales for the last year are greater than in any other year. In the Eastern district the demand for motors was strong and central-station companies continue to buy substation equipment. One order for transformers amounted to $270,000. The volume of sales is satisfactory in the Southeast and is spread over the entire territory. A considerable amount of industrial business is in immediate prospect.

Inquiries are good but sales are off in the St. Louis district. Industrial buying improves in the Middle West and there is little change in general business conditions. On the Pacific Coast industrial ordering is active, although in the Seattle district motor orders are low, with good prospects for future business. Many street-lighting projects are reported. A 200-ton paper mill to cost $6,500,000 is being planned by the Zellerbach interests.

### *Big Demand for Copper Both Here and Abroad*

An enormous demand for copper, which developed to its fullest extent on Tuesday, was the feature of the metal markets. The other non-ferrous metals were fairly quiet, with prices generally well maintained. The copper market, which has been little better than average for the last month, and extremely dull in the East and in the Middle West for many weeks before that, gradually improved until Tuesday, when an avalanche of orders quickly brought every seller up to the full 14⅛-cent Valley quotation. Total sales for the week ended Wednesday have exceeded those of any week since that of Dec. 8, 1926.

Good inquiry and active buying have characterized the domestic lead markets.

NEW YORK METAL MARKET PRICES

| | Mar. 21, 1928 Cents per Pound | Mar. 28, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic | 13.78¾ | 13.90 |
| Lead, Am. S. & R. price | 6 | 6 |
| Antimony | 10¼ | 9¾ |
| Nickel, ingot | 35 | 35 |
| Zinc spots | 6.0½ | 6.046 |
| Tin, Straits | 53¾ | 53 |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper price March 28, 1928, 15¾ cents.

Small premiums over the contract price of the American Smelting & Refining Company, which has remained at 6 cents New York, have been obtained, but the tonnage is not sufficiently large to be reflected in quotations. The leading interest, however, during the last two days has been unwilling to entertain business at the 6-cent level for delivery beyond April.

### *Volume of Sales Satisfactory in the Southeast*

Individual orders placed in the Southeast are small. The demand is virtually from the entire territory and the total volume of business is satisfactory. One company in Georgia ordered creosoted pine poles amounting to $3,400 and bare copper wire amounting to $1,800, while two small companies in the same state ordered line construction materials amounting to $2,500 and $1,000, respectively. One of the larger central-station companies received an order for 72 electric ranges for an apartment house installation and the order for 72 electric refrigerators for the same installation is pending and will undoubtedly be placed during the coming week. The same company also received an order for sixteen refrigerators for an apartment house.

Inquiries, rather than orders, constitute the principal activity in industrial lines, but a considerable amount of business is in more or less immediate prospect. Two medium-sized textile mills in the Carolinas, using large amounts of process steam, are contemplating the purchase of steam turbines. An order was received for $1,000 worth of inside wiring materials for a Georgia fertilizer plant addition. A "white-way" system and additional street lights will be installed at Brunswick, Ga.

Construction items are as follows: The Central Georgia Power Company will extend its 11,000-volt line to the American Clay Company, and install a 300-kva. substation. The Alabama Power Company is acquiring the municipal power plant at Athens, Ala. The Atlantic Ice & Coal Company, Atlanta, Ga., plans a cold storage plant at Buena Vista, Ga. The Chase Bag Company, Memphis, Tenn., plans the installation of a plant addition which is to cost $115,000. The Tubize Artificial Silk Company, Hopewell, Va., plans a new mill to cost $1,000,000. The Orange Textile Mills, Inc., Orange, Va., plans a new mill, to cost $100,000. The Shenandoah Milling Company, Shenandoah, Va., plans a hydro-electric plant on the Shenandoah River to cost $250,000. The Appalachian Electric Power Company plans a substation in the Williamson district, to cost $150,000. The Mississippi Power & Light Company plans a transmission line from Lexington to Durant, Miss. The Carolina Power & Light Company plans a transmission line from Canton to Asheville, with branch to Greenville, S. C., about 70 miles, to operate at 110,000 volts and to cost $250,000. Hickory, N. C., Montgomery, Ala., and Union City, Tenn., are planning ornamental street-lighting systems.

### *Strong Demand for Motors in Eastern District*

Motor sales are decidedly active in the Eastern district. Iron and steel mills, dye and chemical interests, textile mills, metal-working plants, paper mills and the automobile industry are prominent in the demand for equipment. The business in turbine units also is improving and the outlook is encouraging. A dye manufacturing company in New Jersey has placed an order for motors totaling $35,000. A yeast manufacturing concern has contracted for a turbo-generator to cost over $20,000. Chemical interests in West Virginia and Tennessee, now engaged in plant expansion, are in the market for motors and kindred equipment and are expected to place orders at an early date. A shipbuilding company in New Jersey is constructing two large vessels for the Panama Railroad and, while decision is still pending, it is anticipated that electric turbine units will be selected for operation. Business in fractional-horsepower motors is holding up well.

Central-station companies are continuing the purchase of substation equipment. A metropolitan utility has contracted for a quantity of oil circuit breakers and regulators for a local substation. A company in New Jersey has divided an order for 27 transformers, 4,000 kva. each, among three manufacturers, at a total cost of $270,000. Another company placed an order for transformers amounting to $55,000 and for regulators to cost $65,000. A New Jersey utility also has signed a contract for a quantity of high-tension insulators. The demand for insulators has been very sluggish during the past few weeks and still continues spotty. Wire and cable business is lagging, although the prospects for sizable commitments are better. A manufacturer of street-lighting equipment reports an awakening in this line and a number of municipalities in the Eastern district are showing an inclination to make purchases.

Both central station and industrial accounts are fairly active at Philadelphia, although sales are on a reduced basis as compared with this time a year ago. Some of the Pennsylvania power concerns are expected to make early purchases of line equipment and apparatus for substation service. Industrial motors are moving quite actively.

Immediate construction projects in the Eastern district include the following: The A. P. W. Paper Company, Albany, N. Y., plans an addition to cost $1,000,000. The Cortland (N. Y.) County Lighting Company plans line extensions at Preble, Solon and vicinity. The Lockport Light, Heat & Power Company will install a system at Middleport. Albert D. Smith & Company, New York, will build a window shade plant on Staten Island to cost $100,000. The Great Atlantic & Pacific Tea Company, Jersey City, N. J., plans a baking and refrigerating plant at Altoona, Pa., to cost $350,000. A. Schottland, Inc., Paterson, N. J., plans a silk mill at Staunton, Va., to cost $200,000. The Trenton Potteries Company, Trenton, N. J., will build an addition to cost $100,000. Newark, N. J., plans an ornamental lighting system on Hawthorne Avenue. The American Electric Power Company will build transmission lines to Atlantic City and in the vicinity of Wilmington, Del. The Hazleton Heights Silk Company, Hazleton, Pa., plans a mill at Clinton, S. C., to cost $100,000.

### *Industrial Buying Improves in Middle West*

Industrial plant buying is improving in the Middle West. Little change in general business conditions is noted. The automotive and steel industries continue to show improvement. Several of the railroads have placed large orders for equipment, while car loadings indicate a considerable movement of commodities. Utility companies are actively engaged in construction work. An order was placed for 350,000 lb. of copper bar, one for 150,000 lb. of solder and one for 500,000 lb. of triple-braid weatherproof wire. Jobbers' sales are normal. Business is not generally as good in the electrical jobbing line as it was last month at this time.

Construction projects are as follows: The Central Illinois Public Service Company plans an ice plant at Bluford, Ill., to cost $100,000. The Park Air Line Company, St. Louis, plans an aircraft manufacturing plant at East St. Louis, Ill., to cost $100,000. The Fleischmann Company, Chicago, will build a yeast plant at Pekin, Ill., to cost $450,000. Logansport, Ind., plans extensions in its electric power plant. The Iowa Soap Company, Burlington, Iowa, plans a power plant in connection with an addition to its factory to cost $100,000. The Consumers Power Company will build an addition to its steam plant at Grand Rapids, Mich. Willmar, Minn., plans extensions in its municipal power plant. Haskins Brothers & Company, Omaha, Neb., will build an addition to its soap-manufacturing plant, to cost $100,000. The Akron Rubber Reclaiming Company, Barberton, Ohio, will take bids for a new mill at East St. Louis, Ill., to be operated by the Midwest Rubber Reclaiming Company, a subsidiary, to cost about $175,000. The Consolidated Water Power & Paper Company plans an addition to its paper mill at Appleton, Wis., to cost $350,000. The Central Illinois Public Service Company, Springfield, Ill., will serve Laclede, Watson, Mason, Edgewood, Rosamond, Forest City, Topeka, Bishop, Ledford, Rohrer and Dorans. Belleville, Wis., plans an extension of its 6,600-volt line and the construction of a small substation. Janesville, Wis., plans to rebuild the transmission line on the south shore of Lake Ripley. The Wisconsin Power & Light Company, Madison, Wis., plans a transmission line at Clintonville and in the Baraboo district and reconstruction of the line extending from Reedsburg to Pardeeville. Glenview, Ill., Deer River, Grand Rapids and Waseca, Minn., and Lincoln, Neb., plan ornamental lighting systems.

### *Buying in New England Is Well Sustained*

The sales volume in the New England district indicates that buying is steady with increasing symptoms of strength. Particularly is this true of the movement in small motors, which reached an encouraging total of over $50,000. Central-station supplies are moving in small lots and prospects for continued activity are good in view of a number of link-ups planned in Maine and Massachusetts. Wire orders are coming in regularly, and portable electric tools have received some attention. Switch and control apparatus orders have fallen off temporarily and transformers are quiet.

Electric furnaces are being considered by a number of plants and a number of orders are pending final approval. Electric street lighting is active and a list of appropriations amounting to over $100,000 is being considered by a prominent manufacturer. One company states that New England business over the past year was greater than at any time since 1920. Contracts awarded last week reached a total of over $11,000,000. Construction projects are as follows: A hospital under state aid will be erected in Waltham, Mass., at a cost of $1,000,000, and the Boston Ice Company plans an ice plant in Dorchester.

### *Industrial Ordering Active on Pacific Coast*

A week's steady rain on the Pacific Coast has prevented serious crop losses owing to an otherwise dry spring. There are only 42 in. of snow at Summit, the normal being 115 in. Various orders now under consideration include a 100-ton electric crane for Los Angeles, 650 pieces of copper busbars for Glendale, a traffic signal system for Santa Cruz and street lighting projects for Belmont, Willows, Oakland, etc. Industrial ordering is good, comprising such varied business as $3,000 worth of motors for a lumber company, three motion-picture motor-generator sets amounting to $6,000, 100 washing machine motors, 250 mixing machine motors, a gas-engine-driven arc welding set for a steel company and a complete traffic control system for San Jose. Power company ordering is rather quiet, being limited to maintenance material and supply stock orders. The outstanding machinery order covers two heavy-duty circuit breakers, valued at $3,000 each, for the Bay district.

Although prospects for future business are reported exceptionally bright by Seattle jobbers, sales were at a minimum and were the smallest for any week since the first of the year. A few scattered motor orders, small sizes only, were placed by irrigation companies and orchards. The Puget Sound Power & Light Company placed an order for twelve 75,000-volt oil switches and the city of Seattle issued a call for bids for clearing 700 acres of land for the Diablo reservoir site of the Skagit hydro-electric project. The city of Seattle also called for bids for street lights on Union and other streets, costing in excess of $400,000. Longview, Wash., plans extension of street lights to cost $25,000 and Oregon City during March will award a contract for a system on four streets. The Western Cold Storage Company, Wenatchee, will purchase 350 hp. in motors for one of its plants. The Zellerbach interests are planning a 200-ton paper mill to cost approximately $6,500,000 and to operate in conjunction with the 100-ton pulp mill at Hoquiam now under construction.

Construction projects are as follows: The Salt River Valley Water Users' Association, Phoenix, Ariz., plans an 8,000-kw. hydro-electric power plant in the Stewart Mountain district. The San Diego Gas & Electric Company has approved plans for a substation at Oceanside, Calif. The E. H. Edwards Company, South San Francisco, Calif., will build an addition to its wire rope plant to cost $100,000. The Apple Growers' Cold Storage Company, Watsonville, Calif., will build a cold storage plant to cost $250,000. The Walsenburg Creamery Company, Walsenburg, Colo., plans a cold storage plant. The Midland Counties Public Service Corporation will make extensions in substations and transmission lines at San Luis Obispo, Calif., to cost $30,000. The Southern Colorado Power Company will make extensions in its power plant at Lamar, Colo., and will construct a transmission line from Las Animas to Lamar. Richmond, Sacramento, Orlando, Salinas, Los Angeles and Yreka, Calif., plan installation of ornamental lighting systems.

### *Inquiries Good But Sales Off in St. Louis District*

Manufacturers in the St. Louis district report a slight increase in the demand for stock apparatus. The only important orders placed were one for a lot of eight oil well motors amounting to $75,000, and another for an electric locomotive for one of the Southern railroads at a cost of $28,000. Jobbers report business quiet, but several large jobs are being figured.

Construction projects are as follows: The Southwestern Gas & Electric Company, Shreveport, La., plans a steam power plant on the Little River, near Horatio, Ark., to cost $1,500,000. The Hollywood Public Utilities Company, Shreveport, La., plans a power plant. Marshall, Mo., has voted $80,000 in bonds for an addition to its municipal power plant. The Stewart Inso Board Company, St. Joseph, Mo., will build an addition to its plant to cost $200,000. The New State Ice Company, Oklahoma City, Okla., will build an ice plant on West Main Street. The Southwestern Light & Power Company has acquired the municipal power plant at Thomas, Okla. The Myers-Spalti Manufacturing Company, Houston, Tex., will build an addition to its furniture factory to cost $200,000. The Crystal Oil Refining Corporation, Shreveport, La., plans a new refinery at Monahans, Tex., to cost $350,000. Olton, Tex., plans a municipal power plant. The Texas Utilities Company will build a transmission line from Slaton to Tahoka, Tex., to cost $50,000. Clayton, Noel and St. Joseph, Mo., and Fort Worth and Burnett, Tex., plan ornamental lighting systems.

# Activities of the Trade

## Bryant Company Acquires Hemco Manufacturing

The plant, real estate, equipment and patents of the Hemco Electric Manufacturing Company of Bridgeport, manufacturer of molded sockets, plates and other composition parts for electrical fittings, has been taken over by the Bryant Electric Manufacturing Company, Bridgeport, Conn. The acquired plant covers 2¾ acres with 70,000 sq.ft. of floor area.

The Hemco products will be made under the same trade name, but the plant will be operated under the Bryant name, and its products will continue to be distributed by former Hemco distributors and also by all Bryant distributors. The line also will be increased. The Bryant company is taking over the entire personnel, including E. B. McKinley, president of the Hemco company.

## Joslyn Company Takes Over American Jobbers Supply

The Joslyn Company, Eastern division of the Joslyn Manufacturing & Supply Company, has taken over the interests of the American Jobbers Supply Company of New York with branch offices located in Philadelphia, Boston, and Baltimore. The Joslyn Company will continue to sell the same lines of material formerly sold by the American Jobbers Supply Company, consisting of the Seyler Manufacturing Company's pole line hardware and specialties, the Porcelain Insulator Corporation's "Pinco" high-voltage porcelain insulators, and the Joslyn Manufacturing & Supply Company's poles and complete pole line materials and construction tools.

The Joslyn Company has crossarm factories and complete warehouse stocks of hardware and other supplies at Rutherford, N. J. and Baltimore, Md. E. L. Morier, who was formerly Eastern vice-president of the Naugle Pole & Tie Company, Chicago, has been appointed general manager of the Joslyn Company.

## Babcock & Wilcox Gets Order for Deepwater Boilers

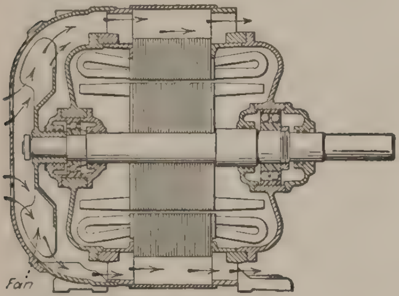
Stevens & Wood, Inc., New York, acting as agents for the American Gas & Electric Company and the United Gas Improvement Company, have placed an order with the Babcock & Wilcox Company for six high-pressure boilers for the new Deepwater plant. Four of these units are standard boilers, 53 sections wide, each section being eight tubes, 3¼ in. in diameter and 20 ft. long, the sections being connected to a forged steel drum 4 in. thick, 52 in. internal diameter and 50 ft. 3 in. long. The heating surface of each unit is 9,623 sq.ft. The boilers are to be equipped with Babcock & Wilcox convection superheaters designed to give an ultimate steam temperature of 725 deg. when the boiler is operating at a rate of 331,000 lb. of steam per hour. The boilers will also be equipped with Babcock & Wilcox wrought steel return bend economizers of the steaming type. Each economizer will contain 18,326 sq.ft. of heating surface.

Two of the units are reheat boilers, the boiler sections having the same size and arrangement of heating surface, and are identical with the standard boilers. The superheaters are of the convection type designed to give an ultimate steam temperature of 725 deg. when the boilers are delivering 290,000 lb. of steam per hour. The reheater elements are of the Babcock & Wilcox wrought steel return bend construction, designed to reheat a maximum of 419,000 lb. of steam per hour at an initial pressure of 385 lb., and a temperature of 487 deg. to an ultimate temperature of 775 deg. The reheat boilers are to be equipped with Babcock & Wilcox wrought steel return bend economizers containing 4,763 sq.ft. of heating surface each. Both standard and reheat boilers are built for a working pressure of 1,350 lb.

# New Equipment Available

## Air-Jacketed Motor

An air-jacketed motor, for use where dust, fumes and moisture are present in sufficient quantities to necessitate protection to the motor, has been developed by the Wagner Electric Corporation, St. Louis. The entire motor, as shown in the illustration, is surrounded by a jacket open at both ends with fan blades on a shaft extension, between the sealed motor and its outer jacket. The only clearance between rotating and stationary parts of the motor is in the bearing housing. The motors are new in external construction only, the company stating that no change has been made in the electrical principles. The end shield is made of cast iron, rib-reinforced, and has a substantial grating which protects the fan and provides an opening for incoming ventilating air. The center shield is made of heavy sheet steel held in place by slot head bolts. The fan is of one-piece construction. The conduit box is mountable in four positions. The exposed outer rim of the stator is deeply grooved to increase radiation surface, and the stator laminæ are welded together to lessen vibration and reduce magnetic noises.



*Inclosed motor with air jacket and ventilating fan*

The motors have a double row of ball bearings, self-aligning in one end plate and deep groove in the other to take end thrust. Bearings are grease lubricated and sealed in a dustproof housing. The shafts are made slightly longer than those for standard motors to permit mounting the fan. Single-phase repulsion-induction motors may be had in sizes from 1 hp. to 20 hp. and polyphase squirrel cage motors in sizes from 2 hp. to 30 hp. These motors are designed for a temperature rise not to exceed 50 deg. C. and to meet all A.I.E.E. and N.E.L.A. standards.

---

MICROAMMETER.—A microammeter of the semi-suspended type is being marketed by the Rawson Electrical Instrument Company, Cambridge, Mass. This instrument is furnished to meet the demand for a portable calibrated meter reading excessively small current values. In this device, known as the type 503, full scale sensitivity is obtained with a current of 0.5 microampere. The scale is about 5 in. long, each division representing 0.005 microampere.

---

## Stroboscope

An electrically operated stroboscope, for determining the angle of lag of synchronous machine rotors under load, has been devised by engineers of the General Electric Company. The new device employs no moving parts or tachometers. It operates by means of a small neon-gas lamp, which gives flashes of light lasting less than one-fifty-thousandth of a second each, and thus illuminates a white line on a stroboscopic disk fixed to the rotor shaft of the machine under test, for so short a time that the line appears to be standing still. Fixed concentrically with the disk, and just outside its circumference, is a stationary scale marked in electrical degrees, and upon this the white line acts as a pointer, giving a direct reading of rotor displacement.

---

## Stoker

Each section of the new Riley superstoker made by the Riley Stoker Corporation, Worcester, Mass., is provided with a damper which is under the control of the operator so that he may supply more or less air, dependent on the fuel conditions at any particular point throughout the length of the stoker. These dampers are controlled from the side wall of the boiler. In the front wall construction means for admitting air over the top of the fuel bed has been provided and is under the control of the operator. The control consists of a sliding damper which is operated by a hand lever at the front of the stoker. Another improvement in the Riley super-stoker over the old design is in the grate block construction. A large diameter and long stroke plunger is used, the disadvantage of a large plunger being overcome by using four grate blocks at the front of the stoker of narrower width and then widening out the remaining grate blocks. This construction is said to give higher capacity and far greater pick-up and flexibility.

The clinker grinding operating mechanism has been redesigned to provide a more variable means of control. The drive for the double roll clinker grinder is so arranged that either or both rolls can be operated as desired. There is also a variable speed provision consisting of a cam which permits the driving pawl of the ratchet to engage one, two or three teeth as desired. The control for the ratchet pawl is independent for either grinder roll so that the speed of one roll can be varied independently of the other.

---

## Heavy-Duty Oil Circuit Breaker for Indoor Service

The type "O-55" circuit breaker for generating station service, built in 4,000, 5,000 and 6,000 amp. capacities at 15,000 volts, with a rupturing capacity of 2,500,000 kva. at 15,000 volts, has been added to the line of the Westinghouse Electric & Manufacturing Company. The breaker units are mounted in a concrete structure with barriers between the units which are supported from the top plate that also carries the operating mechanism. This method of mounting places the barrier walls in compression, utilizing their maximum strength. The breaker is said to be of high mechanical strength. The condenser type terminals are used to pass the conductors through the main base. The contacts are of parallel path construction. The arcing contacts protecting the main contacts are finger and wedge type, easily renewable and heavier than on lighter breakers to take care of increased rupturing capacity.

*Detail of contacts on type O-55 heavy-duty oil circuit breaker*

The electric mechanism consists of a double solenoid designed so that the pull of the closing mechanism closely matches the effort required to close the breaker units at all points of the closing stroke. This gives adequate speed of closing for synchronizing, and at the same time keeps down stresses within the structure. The electric mechanism is equipped with rotary type auxiliary switches for indicating, interlocking and control purposes. A control relay panel is also included in the closing mechanism. The control relay removes the energy from the electric mechanism immediately upon the completion of the closing stroke. The mechanism is mechanically full-automatic; that is, it cannot be held closed, either electrically or mechanically, if the tripping relays disengage the trigger.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued March 6, 1928)

1,661,703. Electrolytic Rectifier; C. E. Ogden, Cincinnati, Ohio. App. filed Aug. 6, 1926.

1,661,712. Electrical Appliance; P. Van Wagner, New York, N. Y. App. filed July 31, 1924. Ground cap for a tube or rod.

1,661,740. Apparatus for Effecting Energization Control of an Electric Circuit; E. R. Stoekle, Milwaukee, Wis. App. filed Aug. 13, 1921.

1,661,776. Storage-Battery Charge Indicator; T. J. Strouse, Pottstown, Pa. App. filed Aug. 13, 1926.

1,661,795. Double-Throw Switch; H. J. L. Frank, Detroit, Mich. App. filed Sept. 4, 1923. With interlocking cover.

1,661,823. Insulator; K. A. Hawley, New York, N. Y. App. filed June 4, 1921. Grading means for high tension insulators.

1,661,824. Motor-Driven Sewing Machine; M. Hemleb, Elizabeth, N. J. App. filed May 19, 1925.

1,661,841. Regulating System; G. R. McDonald, Schenectady, N. Y. App. filed Aug. 30, 1926. For controlling the division of load between two sources of current.

1,661,842. Electric Furnace; J. L. McFarland, Schenectady, N. Y. App. filed June 16, 1927. Means for supporting and securing the resistor.

1,661,850. Electrical System; D. C. Prince, Schenectady, N. Y. App. filed May 18, 1925. An arrangement comprising an electron discharge device for interchanging power between direct and alternating current systems.

1,661,854. Storage-Battery Device; F. C. Ridgely, Detroit, Mich. App. filed Feb. 20, 1925. For holding oil, grease, etc., under a battery post.

1,661,862. Electric Heater; W. N. Vanatta, Ontario, Cal. App. filed Dec. 29, 1924. Means for protecting electric heaters from overheating.

1,661,883. Electric-Ship-Propulsion Installation; E. D. Dickinson, Lynn, Mass. App. filed July 19, 1922.

1,661,902. Feed-Wire Support; N. A. Michaelson, Uniontown, Pa. App. filed May 27, 1927. Supporting device for feed wire of a trolley wire.

1,661,909. Electric Clock; C. E. Prince, Burchetts Green, England. App. filed Aug. 6, 1924.

1,661,913. Battery Tester; J. Taylor, Chicago, Ill. App. filed Jan. 22, 1927.

1,661,923. Rotary Rectifier; C. M. Clay, Mexico, Mo. App. filed June 2, 1923.

1,661,928. Electric Lamp; W. Dawson, London, England. App. filed May 23, 1927. Multiple filament type.

1,661,945. Dry Cell; W. F. Hendry, Ossining, N. Y. App. filed Jan. 23, 1924.

1,661,970. Electric Welding Machine; F. L. Sessions, Lakewood, Ohio. App. filed Jan. 13, 1923. For welding longitudinal seams in thin wall drums or the like.

1,661,994. Automatic Porch Light; G. H. Brown, Nevada, Mo. App. filed Oct. 22, 1921.

1,662,027. Tungsten Product and Its Manufacture; A. de Graaff, Eindhoven, Netherlands. App. filed April 24, 1928. To prevent the sagging of a tungsten filament.

1,662,031. Electrically Heated Device; F. H. McCormick, Glen Ellyn, Ill. App. filed Sept. 11, 1925. Such as ovens in which suitable mechanism is provided for automatic heat control.

1,662,045. Lamp-Making Machine; F. W. Patterson, Arlington, N. J. App. filed April 22, 1924.

(Issued March 13, 1928)

1,662,055. Connecting Device; H. P. Chandler, Mansfield, Ohio. App. filed May 13, 1925. For making temporary connections to a conductor.

1,662,071. Regulating System; E. C. Manderfeid, Boonton, N. J. App. filed Aug. 4, 1926. To regulate mechanical or electrical characteristics, as for example, speed, frequency or voltage.

1,662,075. Electrolytic Rectifier; A. B. Muntyan, Amsterdam, Netherlands. App. filed Oct. 15, 1924.

1,662,083, 1,662,084, 1,662,085. Electric Regulator; H. M. Stoller, Mountain Lakes, N. J. Apps. filed Aug. 4, 1926. For regulating the speed or frequency of dynamo electric machines.

1,662,107. High-Tension Electric Cable; L. Emanueli, Milan, Italy. App. filed Sept. 1, 1925. Of the type in which the strands of the conductor are supported by a hollow metallic core and through which oil flows and impregnates the insulation that surrounds the conductor.

1,662,114. Flashing and Regulating Apparatus for Discharge Tube Display; F. Hotchner, Los Angeles, Calif. App. filed March 9, 1927.

1,662,122. Pressure Actuated Circuit Control; I. E. McCabe, Chicago, Ill. App. filed Feb. 11, 1922.

1,662,132. Inductance Apparatus; B. J. Simmons, Stillwater, Minn. App. filed Nov. 16, 1925. A compound electromagnetic cycle.

1,662,149. Electric-Furnace Voltage Control; A. E. Greene, Medina, Wash. App. filed Jan. 3, 1913.

1,662,174. Electromagnetic Relay; E. W. Seeger, Milwaukee, Wis. App. filed May 17, 1920. Responsive to undulating currents.

1,662,233. Trolley Wheel Carrier; C. W. Brown, Los Angeles, Calif. App. filed Dec. 15, 1924.

1,662,243. Controller for Electric Motors; C. T. Evans, Milwaukee, Wis. App. filed May 8, 1922. For direct current motors.

1,662,245. Yieldable Connecter for Electric Cables; C. M. Goodrich, Windsor, Ont., Can. App. filed June 14, 1927. For suspending high tension electric cables from the arms of towers and other overhead supports.

1,662,252. Electric Regulator; E. R. Morton, New York, N. Y. App. filed March 12, 1925. Electron tube regulator for electric generators.

1,662,275. Switch Box; J. L. Lane, Chicago, Ill. App. filed May 19, 1924. With safety locking device.

1,662,334. Street Light Fixture; F. B. Reberg, Casper, Wyo. App. filed Nov. 24, 1924. Bracket suspension for street-hood bodies for street lighting.

1,662,335. Spring Socket Terminal; L. Reichold, Winsted, Conn. App. filed Nov. 26, 1926. For use with the quick detachable jack and plug connections for portable electrical utensils.

1,662,346. Battery Terminal Clamp; R. B. Stewart, Crows Landing, Calif. App. filed Nov. 19, 1925.

1,662,349. Storage Battery; G. K. Thompson, Summit, N. J. App. filed Aug. 31, 1923.

1,662,366. Automatic Electric Service System; M. C. Cosgray, Sandusky, Ohio, App. filed April 23, 1923. An auxiliary source of supply of electric energy that will be automatically connected when the main supply falls below a predetermined amount.

1,662,369. Arc Welding System; J. Kjekstad, Brooklyn, N. Y. App. filed Aug. 1, 1918. Applicable to both carbon arc welding and to metallic arc welding.

1,662,383. Electrolytic Rectifier; W. H. Grimditch and J. N. Hunsberger, Jr., Philadelphia, Pa. App. filed Feb. 18, 1927.

1,662,434. Control Mechanism; M. W. Palmer, New York, N. Y. App. filed Jan. 4, 1927. Automatically operating controlling mechanism whereby the voltage in a line may be maintained within very close limits.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Santiago, Chile (No. 30,300), for storage batteries.

Purchase is desired in Panama City, Panama (No. 30,235), of electric dishwashers.

Purchase and agency are desired in Amsterdam, Netherlands (No. 30,236), for dishwashers, potato peelers, ice-cream freezers and other electric kitchen equipment for hotels, hospitals and steamships and electric refrigerators.

Purchase and agency are desired in Hamburg, Germany (No. 30,241), for electric laundry machinery.

An agency is desired in Barcelona, Spain (No. 30,254), for oil burners with motor and compressor.

# New Trade Literature

MOTORS—"Lincoln 'Linc-Weld' Motors" is the title of a bulletin issued by the Lincoln Electric Company, Cleveland, in which it describes its "Linc-Weld" method of motor construction, showing in detail the use of welded steel. An illustration is given showing a phantom view of a standard Lincoln "Linc-Weld" motor. Attention is called to its automatic induction controller, the "Linc-Weld" switch-start motor, and the stable arc welder.

MOTORS, STARTERS AND TRANSFORMER RATIO ADJUSTERS.—The General Electric Company, Schenectady, N. Y., is distributing bulletins GEA-808A, GEA-137A, GEA-467A and GEA-147B, describing and illustrating respectively its forms RA and RL totally inclosed fan-cooled induction motors "500 series," types TS and QS "6000 series" synchronous motors for mounting on compressor shafts, CR7022 automatic starters for slip-ring motors and power transformer ratio adjusters.

WATT-HOUR METER. — The Sangamo Electric Company, Springfield, Ill., has issued a bulletin in which it describes and illustrates the Sangamo type HC watt-hour meter. Illustrations show the construction of this new meter. Included is a table of train ratios and disk constants and a series of curves showing the meter accuracy with change in load, change in temperature, change in voltage and change in frequency.

ELECTRIC RANGES AND PANELBOARDS.—The Benjamin Electric Manufacturing Company, 120 South Sangamon Street, Chicago, has issued catalog No. 302A, covering its new "Consolette" electric ranges. Illustrations showing the various types of the ranges are given and a description of the construction of the "Consolette" range is included. The company also is distributing a bulletin on the "Little Sentry" line of panelboards with or without arrangements for branch circuit tumbler switches, recommended for residences, apartment buildings, schools, small stores and factories and similar places having from four to twelve branch circuits.

RAILWAY EQUIPMENT. — Bulletins GEA-797, GEA-872, GEA-921 and GEA-951 issued by the General Electric Company, Schenectady, N. Y., describe and illustrate respectively the repair of commutators of railway and industrial-haulage motors, drum type controllers for railway service, better lubrication for G-E 265 railway motors and the "Mazda" C short-circuiting lamp and socket for 600-volt railway circuits.

METER RECORDS.—"What Can You Do in Fifteen Seconds" is the title of a catalog issued by the Kardex division of the Remington Rand Business Service, Inc., 374 Broadway, New York City, covering its meter record system. How the Erie County Electric Company applies the method to its system is described. Attention is called to the fact that the record is not only a meter record but also serves as an address record and a test record. A complete description of the system is included and a sample of the cards used are attached to the catalog.

NEON TUBES AND ACCESSORIES.—The New Jersey Neon Light & Power Corporation, Camden, N. J., has issued a catalog covering "Neon" tubes and "Neon" accessories for sign work.

POLE LINE MATERIAL.—A catalog issued by the Oliver Iron & Steel Corporation, South Tenth and Muriel Streets, Pittsburgh, Pa., covers a condensed listing of Oliver pole line hardware and construction specialties. The various products listed are all illustrated and described.

CABLE RACKS AND SWITCHES.—The Metropolitan Device Corporation, 1250 Atlantic Avenue, Brooklyn, N. Y., is distributing a bulletin in which it describes and illustrates its cable racks for manhole, vault, station wall and service box mounting, and other underground distribution devices. Photographs show some special cable vault installations. The company has also issued a pamphlet covering meter service switches, the accessible main fuse type with testing facilities and accessible branch fuses combined.

RECORDING INSTRUMENTS AND LIMIT SWITCH. — Bulletin GEA-927 issued by the General Electric Company, Schenectady, N. Y., covers its type CP-4 and CP-5 alternating-current portable recording instruments. The company is also distributing bulletin GEA-914, describing the CR9441-LS424A limit switch for use on control circuits only.

## *Why Should Municipal Plants Be Exempt from Supervision?*

WHAT is there so sacrosanct about the business of government, and especially municipal government, that its exponents are moved to insist that government shall be a law unto itself and that it shall not be subject to constant scrutiny and examination? Government is the greatest business in the country, and yet in most instances it is the most poorly conducted. Whence, then, the cry "Touch not mine anointed"? Regulation and supervision are exercised over all public utility corporations except the vast majority of those municipally owned and operated. To the latter are granted indulgences, so to speak, and they receive preference over utilities otherwise owned. Why? Surely not because they give a better service or because their affairs are managed with more scrupulous regard for the rights of the public. On the contrary, they are, if anything, more remiss than ordinary corporations in rendering an account of their stewardship to their stockholders—that is, to the public. Men who are elected or appointed to public office seem to forget that they are servants, not masters, and that powers of office are a public trust.

Consider the catastrophe which overtook the inhabitants in the San Francisquito Valley of California recently by the failure of the St. Francis Dam. Hundreds of lives were lost because of the derelictions of municipal engineers whose work was not subject to state supervision. When a few years ago some dams failed in San Diego County the Legislature of California passed a law requiring supervision and inspection of dams by the State Engineer. When the measure was first introduced it provided for supervision of all dams, but a proviso was later slipped in at the instigation of lobbyists (mark the word and by whom they were employed) exempting municipalities having their own engineering departments. When a public utility company erects a dam in California the work is subject to the approval and continuous inspection of the State Engineer and also of the Public Service Commission. The dam erected by the Los Angeles municipal Water and Power Department was never inspected by any one but itself.

This incident also brings up some question regarding the Boulder Canyon Dam on the Colorado River. There are engineers who feel that the Boulder Canyon project has not received careful scrutiny from engineers not interested directly in it. There are others who, in the light of the St. Francis Dam failure, point to the enormous hazards involved in holding back such an immense quantity of water by a single dam of huge proportions. Before the government spends hundreds of millions at Boulder Canyon would it not be well to give further thought to the entire matter—first, to determine whether the engineering plans and the location are all that is claimed and, second, to ascertain whether it might not be better to impound the water of the Colorado in a number of smaller dams, one of which could be built near Needles for immediate protection and the others erected farther upstream than Black Canyon? Certainly, the experience in the San Francisquito Valley should cause very serious inquiry and thought to be given to the Boulder Canyon project, which will impound 720 times as much water as was unloosed by the failure of the St. Francis Dam.

## *"Legalizing" Preferreds and Debentures*

UTILITY preferred stocks, notes and debentures are commencing to enter the door of the "legals" in New York State by the terms of the Wales law, passed by the Legislature in its closing days. This law is but another step taken in recognition of the necessity of widening the field of available investment of funds by regulated institutional investors. By its terms life insurance companies — long restricted to real estate mortgages, corporation mortgage bonds and various government obligations—may now invest in the preferred and guaranteed stocks and in the notes of corporations whose earning history is satisfactory as defined by the law.

While they are not referred to specifically, an examination of the securities coming within the provisions of the law discloses that many preferred stocks and debentures of electric light and power companies—both holding and operating—are thus "legalized." To those who are observant this is as it should be. For the untarnished record of preferred stocks in this industry, as well as the even stronger position of the debentures, has long recommended these securities to the discriminating institutional investor who was free to purchase them. Note, for example, the investment list of the Sun Life Assurance Company of Canada as mentioned in these columns last week. This company is well known in the United States for its careful study and keen judgment in investing its funds, and its list shows large amounts of American utility debentures, preferred stocks and even common stocks.

As in the case of legalizing bonds for savings banks and trust funds, so this move has an effect on the yield rate at which securities affected by it may be issued. The total volume of money released to flow into these channels is not very large, comparatively, but the effect of the law was immediately felt in Wall Street. At least one issue then in negotiation between company and banker was increased in price to take advantage of the new tone of the debenture and preferred market which resulted from the law's passage.

From the standpoint of the insured, laws like this will allow insurance companies to invest in securities of higher yield and thus keep down the rates for insurance. From the standpoint of the companies whose security prices are affected by this increased demand from the insurance companies, the new law indirectly makes it possible to obtain funds from unsecured obligations and preferred stocks at lower yield. But it must be remembered that the primary object of the law was the one stated first, and that certain utilities may benefit in the second way is due to the fact of their past record of performance having placed their securities in a preferred class, now officially labeled "safe." It is a record which deserves to be, and doubtless will be, maintained and zealously defended, and all companies will have this additional inducement to shape their financial structures and formulate their financial policies along lines that will enable them to qualify their securities among the "legals."

## *Blame for Cable Failures*

WHO is to blame? This is often a difficult question to answer, resulting in sharp differences of opinion even in the accidents of ordinary life. When it is a case of electrical trouble or failure, the answer is particularly difficult because so often the results of such failure destroy the evidence. A striking instance is the failure of a high-voltage underground cable, a most serious form of trouble, the means of preventing which is the constant study of manufacturers and operating engineers. When the cause of this type of failure is sought there is little use in examining the cable. The blow-out usually destroys the path over which it starts, and deductions in explanation are subject to great uncertainty.

To the discussion of the cause of cable failure there are two principal parties—the operating company and the manufacturer. Each would like to think the other to blame. The search for evidence is largely controlled by the operator. He is immediately on the job and has available the operating history immediately preceding the accident. The manufacturer, if he comes in at all at this stage, hears about it some time afterward, and he must content himself with such information as the operator gives him. He can ask the conditions of operation, and it is, of course, recognized that disturbances of other character in the operation of a large system may lead to the failure of cables which would probably show normal life under normal conditions of operation. This is the refuge of the manufacturer in the face of the accusing finger of the operator.

There is another important factor in this question. The operating companies are organized in several well-known national associations. The manufacturers, however, owing to their competitive relationship, have no such common ground on which they can seek measures of mutual protection against the frequent claim of the operating companies that cable failures are largely due to defects of manufacture. The National Electric Light Association has published through a number of years the records of cable failures in which some attempt is made to segregate these failures as due to cable defects or to operating conditions. In addition, similar data are given as to joint failures. Some of these reports are accompanied by quite definite suggestion that many of the cable failures are to be laid at the door of the manufacturer. The manufacturer replies: "Some perhaps, but not so many as you think."

A close study of the N.E.L.A reports for the years 1923-1926 seems to yield somewhat more light on these differences than appears on the surface. For example, of the total cable failures reported, those due to injuries under service conditions are double in number those classified by operating companies as due to defective cables. There is at least some likelihood that many failures ascribed to deterioration, defective workmanship and "X" wax are in reality due to manufacturing defects; if this were so, the number of these failures should be practically independent of the particular operating company on whose system the cable operates. From the data this is by no means so, and in fact it may be seen that if a company has a great number of total failures or a great many operating failures, this condition is accompanied in almost all cases by a large number of cable failures. It is also possible to correlate the reports on joint failures in such a way as to indicate that a portion of the defects attributed to manufacture in all probability are the results of joint failures. From which it might be argued with some force by the manufacturer that attention to general operating conditions and to general methods of installation in the direction of improvement would probably also result in a reduction of failures classified as due to manufacture.

## *Sanity in Station Design*

IT IS well to appraise values in power-station design at frequent intervals. The time is ripe for a study of dollar economy based on the costs and performances of new stations that embody departures from past practices and that differ one from another in many features. Total energy cost at the switchboard, and not thermal economy, is the ultimate gage of merit. Complexity, automatic equipment, large units, reserve lines of defense, purpose of station, labor cost and many other items offer themselves for study. Automatic equipment is justified only as it reduces labor costs and improves performance—it is expensive, adds to the complication of the plant, requires high-grade maintenance men and must justify its use on an economic basis. The craze for high thermal economy leads to the use of high pressures, high temperatures, two fluids, reheating, preheated air, special furnaces and other things which are good only as their use reduces the total cost of generating energy during the normal life of the station. Fuel is too cheap to permit of glorified design at the expense of station costs.

Then on the electrical side there is a large amount of money spent for double buses and breakers, protective devices, reserve auxiliary and excitation supplies, switch houses and other items which may or may not be justified for each power station. No property can use a standard station design without spending money to excess, but, on the other hand, no property can without losing money make individual station designs as regards details of equipment which depart from standard.

Simplicity, reliability, minimum labor in cost and volume, lowest over-all cost of energy, suitability for service conditions and ease in operation and maintenance are the important factors in power stations. With many now in operation that have a 100 per cent cost variation per unit of capacity and with every conceivable type and arrangement of equipment installed, it would be well worth while to appraise the operating plants so that new designs could benefit. Any defensive position which might be taken by plant engineers to cover errors and inconsistencies must give way to a constructive attempt to make new stations better and cheaper through the use of the experience available. Past mistakes are forgivable, but they should not be repeated.

## *Electric Homes for Egyptian Ones*

IN ANCIENT times men built homes of wood, brick and stone by hand labor and with crude methods of construction. Even today our homes are the crudest and least efficient assemblies of these ancient materials and afford a sad commentary on the lack of initiative among modern builders and home owners. Home building follows Egyptian practices despite the advent of iron and cement and the development of skyscraper architecture. For housebuilding purposes metal pieces welded together, with fireproof fillers for walls and partitions, offer a means to get comfort and beauty at low cost. Fireproof structures of infinite variety can be built of modern materials in the modern way, and the current attempts to introduce these ideas to home owners should be encouraged by the electrical industry.

A steel-frame house with a solidly grounded neutral of bare metal offers attractive possibilities for reducing wiring costs. Methods of wiring and of installing illumination could utilize the advantages that pertain to a grounded structure. Whether heated by electricity or fuel, this type of home could have insulated walls and partitions that would save heat energy in cold weather, and in warm weather air refrigeration would be placed within the bounds of possibility. With the insulated, ventilated and flexible home possible by the employment of modern materials and construction practices there is no valid reason why the American home should remain either a square wooden box, a stone pile or a mound of unsightly bricks. Fondness for the antique can be carried to extremes.

## *Effect of the New Radio Law*

CONGRESS has passed the radio bill. The President has signed it. It is the law. The electrical industry is wondering just what it means. The electrical industry is interested because radio is fast becoming an energy-consuming appliance important to the power companies, because many electrical manufacturers are making radio parts or sets, because electrical jobbers and dealers are selling radio merchandise, and because electrical contractors are installing radio wiring. Electrical men, therefore, have a valuable stake in the prosperity of the radio industry and are concerned over what the effect of the new law may be.

In a word, the life of the Federal Radio Commission has been extended one year, but there has been imposed upon the commissioners an amendment that demands that each zone shall have an equal number of stations, an equal amount of power and an equal number of wave channels and that within zones these shall be allocated according to the population of the states within the zone.

[illegible] the technical standpoint it is a difficult situation. No one would think of demanding that there be an equal mileage of railroads in every zone, or an equal production of electric power, or an equal number of telephones. No one would ask that there be an equal number of letter carriers. This is now required of radio, however, despite the obvious fact that broadcasting studios must naturally be located where artists are available and that therefore the great studios of New York and Chicago are providing programs of a quality that cannot be achieved in smaller communities.

But, on the other hand, it is also a fact that New York or Chicago stations, even with superpower, cannot carry into distant Southern and Western states. It is for this reason that the networks have been organized. It is also true that these networks are not yet extensive enough to enable the entire United States to enjoy the advantage of the big-city programs. It is this condition that the new legislation proposes to overcome. What will be the effect of this law? The commission is now endeavoring to solve the intricate problems of its application.

It may influence the expansion of chain broadcasting from the big studios by wire to more new and modern stations that eventually will cover the entire country. It may lead to the organizing of more good studios in smaller cities across the map. In any event, the program should provide for the continuing development of high-powered broadcasting that guarantees good service in warm weather. For, after all, what the public wants and what the electrical industry wants is just good reception of the best possible programs available in every home—at all seasons, no matter where. This should be the aim.

* * * *

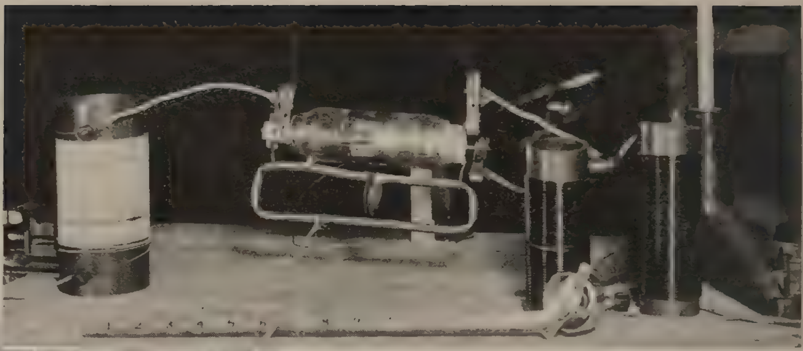
## *Conductor Movements Influence Line Design*

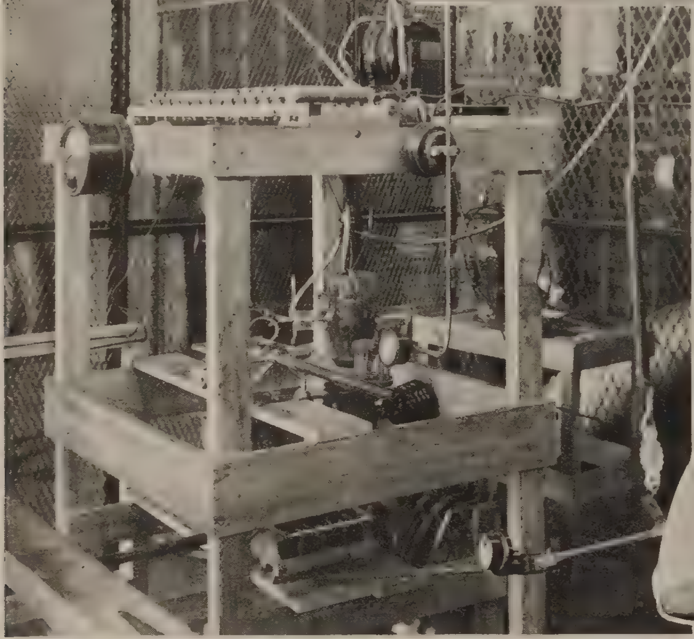
TESTS conducted by the Bureau of Power and Light of Los Angeles to determine movements of overhead conductors under short-circuit conditions revealed conductor movements which indicate that short-circuit forces are a factor that must be taken into consideration in overhead-line design. Virtually no information was available on the subject when the bureau undertook its investigation, and the results of its tests should prove of great value to the industry.

Efforts to calculate conductor movements proved unsatisfactory, and full-scale tests had to be resorted to. Tests were made at night when sufficient generator and transformer capacity was available to supply the high short-circuit currents necessary. Conductor movements were measured by an ingenious photographic method which gave a graph of the actual path followed by the conductors. On a 150-ft. span with No. 4/0 conductor, spaced 4 feet and strung under a tension of 10,400 pounds, the maximum throw of the conductors from their original position was 4.07 feet with a short-circuit current of 12,700 amperes maintained for 1.05 seconds. Numerous other tests were made, but this one example serves to indicate the very violent movement of conductors to be expected under what may be called normal conditions obtaining on a 2,400-volt distribution circuit within a few blocks of a substation.

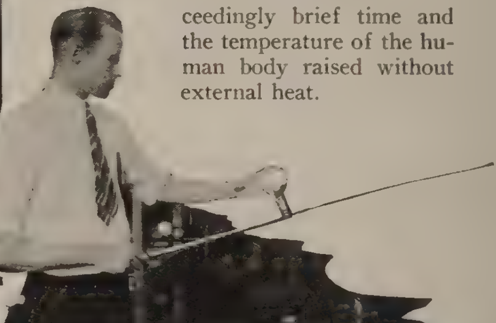
Span length, conductor size and spacing, tension and short-circuit current are the principal factors to be considered in conductor movement under short-circuit forces. Length of spans, conductor size and spacing and tension have been determined in the past largely without regard for conductor movements due to heavy short-circuit currents, but it is now evident that this latter factor must have careful consideration also. Load conditions will largely determine conductor size, and there are physical and economic limits which are soon reached as spans are reduced in length and wire spacing is increased. The obvious remedies, then, that suggest themselves are limiting of short-circuit currents by the use of current-limiting reactors, breaking systems up into smaller loosely coupled units, underground distribution, and some mechanical means of preventing conductors from being violently repelled and coming together on the back switch.

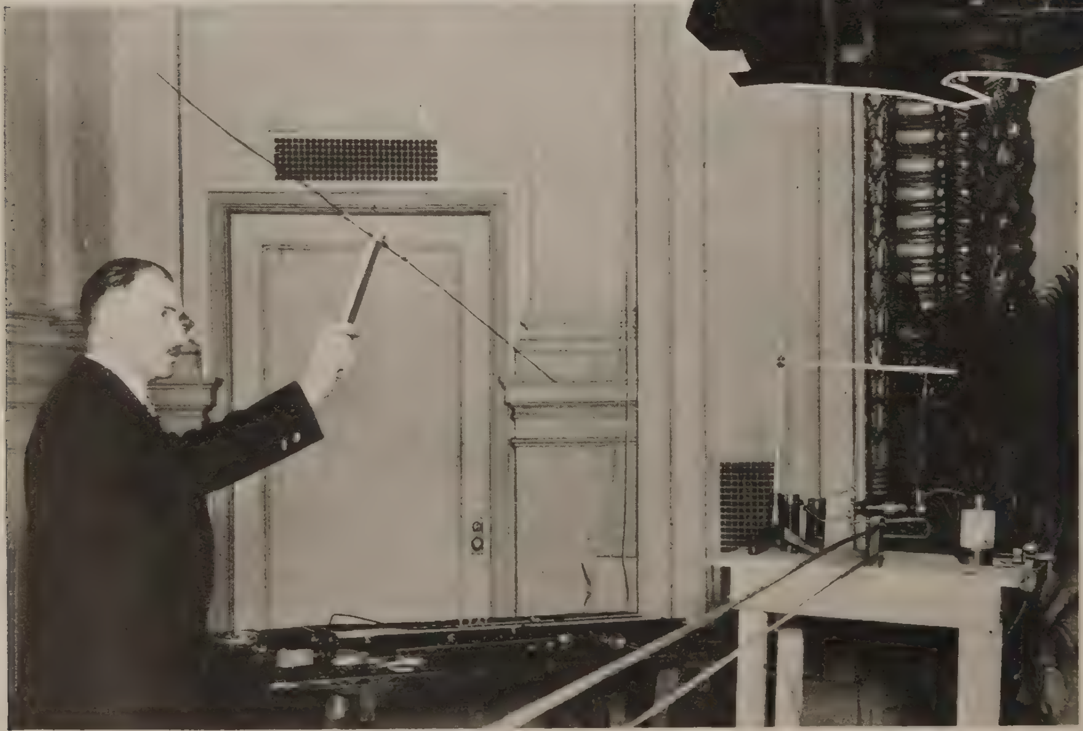
# *Short-Wave Power Transmission*





HIGH-FREQUENCY, vacuum-tube oscillators of the designs illustrated have recently been developed in the laboratories of two American manufacturers. Standard filament lamps and neon-filled tubes may be lighted through contact with isolated conductors of such length as to offer resonant response to the transmitted waves. Food may be brought to a "cooked" condition in exceedingly brief time and the temperature of the human body raised without external heat.





# Loaded High-Voltage Cables

Calculations on 132,000-volt cable for long-distance transmission. Shunt vs. series loading considered and method of calculation outlined

By A. F. PUCHSTEIN
*Assistant Professor of Electrical Engineering, Ohio State University*

THE recent installation of two 132,000-volt cables, which was announced in the ELECTRICAL WORLD for Sept. 3, raises some interesting questions as to what may be expected from such circuits when used for longer distances. At present the circumstances necessary to make such an installation economically feasible do not exist. It is believed, however, that a review of some of the problems met with and the possibilities of loading will be of interest.

Information previously published indicates that these cables have an insulation thickness of $\frac{2}{3}\frac{3}{2}$ in. The conductors are hollow with an area of 600,000 circ.mil. The external diameter is 3.1 in. The rating is about 90,000 kva. at a carrying capacity of about 300 amp. The resistance of a conductor is about 0.095 ohm and the capacitance 0.366 mfd., both per mile. The cable requires a charging current of 10.5 amp., or 2,400 kva. per mile at 60 cycles.

Obviously, this cable cannot be used for distances greater than roughly 30 miles, because the charging current would then exceed the carrying capacity. What, then, would happen in the case of distances of, say, 100 or 200 miles? Even if the cost can be reduced sufficiently, it will not be possible to use cable under this condition, unless a way can be found to reduce the capacitance or unless some form of compensation is employed. There is not much hope of reducing the former, hence recourse must be had to the latter. Compensation would be desirable even if the inductivity of the insulation used could be reduced to unity.

For this purpose the use of shunted reactors connected at intervals across the line is most suitable for all distances. The idea was proposed by Bradley for use with overhead lines about 29 years ago and S. P. Thompson for telephone circuits about 33 years ago. Such inductances serve to neutralize the effects of line capacities. The action is best if the coils are not too far apart. Spacings of the order of 25 miles would be suitable. Bradley's scheme was never used because the low capacitance of overhead lines made it unnecessary. The Thompson idea was never used in communication work because series loading gives more nearly equal attenuations at the different frequencies. Shunt loading is not affected by voltage variations.

In power cables we are concerned with only a single frequency and the defects of shunt loading do not trouble, whereas its advantages make it a possibility. The growing use of power cables seems destined to revive this type of loading. No coils suitable for this purpose have been developed, but no difficulty is expected. Such a coil would be similar to a high-tension transformer with a core specially designed to require a large magnetizing current and the secondary winding omitted. This would be accomplished by using a core material of higher reluctance than customary or by including an air gap in the magnetic circuit.

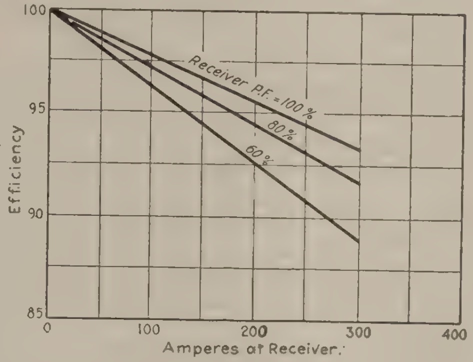


*Fig. 1—Efficiency of 200-mile, three-phase, 132,000-volt, 600,000-circ.mil cable devoid of capacitance and leakance*

An alternative arrangement would be to use step-down transformers to feed reactors or synchronous motors, but either of these would be less efficient and more expensive. The delivered voltage can be regulated by synchronous motors in the usual way, keeping in mind the lower reactance of cables as compared with overhead lines. When necessary for purposes of regulation enough series reactance may be added artificially.

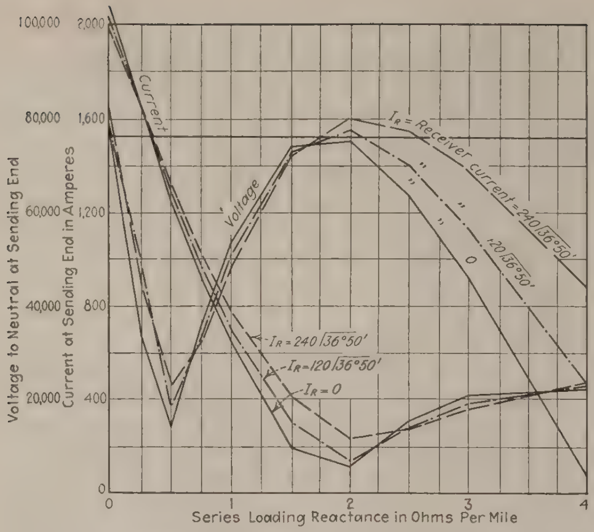

*Fig. 2—Calculated performance of 600,000-circ.mil series loaded power cable for different receiver loads at 132,000 volts and 80 per cent power factor. Distance 200 miles*

In order to give some idea of the results to be expected from a 200-mile length of the above cable, the following results are offered:

Table I shows the principal items of performance of the unloaded cable when delivering, respectively, 0, 120 and 240 amp. at 132,000 volts for a lagging power factor of 80 per cent. Observe the large values of current and power at the sending end and the low efficiency. The current at the sending end is about seven times the carrying capacity.

If there were no capacitance or if it were neutralized without loss so that the cable would behave as an ordinary "short" line, the efficiency under different conditions would be as shown in Fig. 1. This represents the ideal that would be attained if the application could be made without introducing new losses.

When shunt loading is applied, the coils take the place of the larger part of the generating capacity that would be required for the plain cable, with the added advantage that they supply the charging current at points along the line where it is needed. This current does not then need to travel over the line. When considered in the same way as transformers, the total rating of coils needed per conductor would be about $13{,}200 \div \sqrt{3} \times 2{,}090 =$ 159,000 kva. The losses in such coils would not be as great as in the corresponding transformers, because there is no secondary winding. A 3 per cent loss based on the kilovolt-ampere rating, or 4,900 kw., would be a conservative figure. The exact total loss between generator and receiver may be found from the longer lines theory. For the present purpose it is sufficient to take

$$\textit{Line Input} = \frac{\textit{Line Output}}{\textit{Efficiency From Fig. 1}} + \text{Total Coil Loss}$$

The values so obtained will not differ seriously from the correct figures. The results when using this approximate calculation are as given in Table II. The kilovolt-amperes at the generator end were taken as the quadrature sum of the reactive kilovolt-amperes at the receiver end and the sum of the kilowatts necessary to cover the receiver load, line copper loss due to receiver load current, and coil losses. This neglects the line copper losses due to the coil loss current, although in this example they would be appreciable. The efficiency is

markedly less than for a "short" line, but is roughly double that of the plain cable.

When the capacitance is neutralized, the regulation may be calculated in the same way as for a short line. The actual figure will be modified by the power current necessary to supply the coil losses. This factor was neglected in Table II.

The results show that shunt loading is capable of considerably improving the efficiency. It equalizes the current so that it is brought within the carrying capacity at all points. The generating capacity that would otherwise be necessary to charge the cable is replaced by cheaper apparatus in the form of loading coils. There is practically no Ferranti effect and cables may in this way be used for voltages and distances that would be impracticable otherwise. It is beyond the scope of this article to discuss the relative merits of coils and synchronous motors.

### SERIES LOADING FOR POWER CABLES

Although this scheme has never been proposed for improving the performance of power cables, it is instructive to compare the results with those previously given. The calculations were made under the assumption that the application introduces no additional losses. The figures represent the highest theoretically attainable values for ideal coils having no copper or core losses. Fig. 3 shows that the efficiency increases markedly with increase in reactance, reaching values above 80 per cent, but this would be considerably reduced if the coil losses were taken into account. The current is not uniform along the line and greatly exceeds the carrying capacity in certain regions. The voltage, also, will not be uniform along the line. These two factors are the fatal objection to this type of loading. It is effective only after the length of line exceeds a certain value, roughly about 100 miles. The total coil rating required is very considerable and is quite comparable with that needed for shunt loading. With nine coils per wave length, which are necessary to approximate a smooth line, the coil spacing would not need to be much less than 25 miles, although when spaced so far apart the coils would have to carry a considerable difference of potential. Fig. 2 shows the relation between sending-end voltage and current for three different receiver loads with different values of loading reactance. Such a cable would be cable of giving a good regulation under certain conditions. The principal constants are given in Table III.

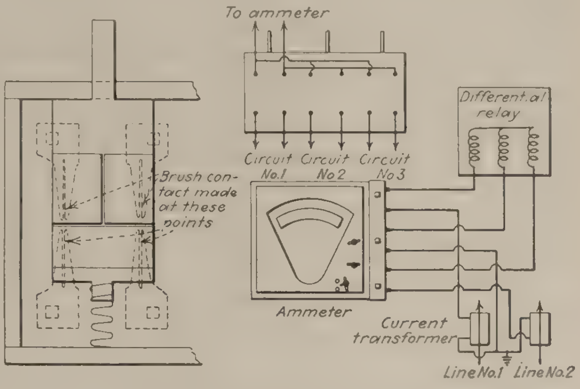
# Three-Circuit Ammeter Switch

By JAMES C. JACKSON

*Detroit Edison Company, Detroit, Mich.*

ANY change in routine-test methods or equipment which reduces the number of pieces of apparatus that must be carried is appreciated by the field test man. One ammeter, and in some cases two, is eliminated from certain routine tests on the system of the Detroit Edison Company by the connector switch here described.

This piece of apparatus was designed to enable testers in the relay division to read the current in any one of the three circuits of a General Electric type PD 3 differential relay on the same ammeter. The device, as shown in the accompanying illustrations, consists merely of three push switches, normally holding the transformer secondaries closed, so designed and connected that the ammeter is cut into any one of three circuits by depressing the proper key. The switches are mounted in a bakelite box as shown. The test circuit for which the device was made is shown in the drawing. Tests are usually made with the lines dead, and currents of 200 to 400 amp., at about seven volts, obtained from a loading transformer are passed in series through the primaries of current transformers on like phases of the two lines. Under this condition there should be equal currents in the holding coils of the relay and no current in the dif-



*Design and connections of three-circuit ammeter switch*

*Three-circuit switch and manner of attachment to ammeter* ferential coil. These three readings are taken on the ammeter by depressing the keys in turn. The device may be connected into the secondary circuits of live lines and used in the same way.

This ammeter switch may be used for many other purposes than that for which it was originally designed. Among these uses are: Taking readings in three phases to determine unbalance; with current transformers on two conductors of a three-phase line to determine the current in the third conductor by depressing two keys together; or, by using a single-phase power-factor meter, the power factor of a balanced three-phase load may be arrived at by determining the angular relations between the currents in two conductors and any one voltage between phases. To these suggested uses many more might be added, their number being limited only by the ingenuity of the operator. It is apparent, also, that the number of switches in the box may be changed according to the variety of uses for which the device is contemplated.

## Cables Racked on Iron-Pipe Supports

By T. W. Swartz

*Assistant Engineer Underground Department,*
*Northwestern Electric Company, Portland, Ore.*

ECONOMY, flexibility and time saved in rigging have led the Northwestern Electric Company, Portland, Ore., to rack cables in vaults as shown in the accompanying illustrations. Black iron pipe nipples $1\frac{1}{4}$ in. x 4 in. are imbedded in the vault walls at the time the concrete is poured. Into these nipples are inserted 1-in. x 14-in. pieces of pipe for supporting the cables. Grooved wood blocks are slipped over these long nipples to provide a bearing for the lead cables. The imbedded nipples are spaced 8 in. or 10 in. vertically, depending upon the voltage of the cable to be racked. Horizontally they are spaced 2 ft. to 3 ft., depending upon the size and type of cable.

A $\frac{3}{4}$-in. bolt with nut and washer support the nipples in the form work while concrete is being poured. The bolt later is removed, leaving the nut imbedded in the concrete. A tapered eye threaded for the $\frac{3}{4}$-in. nut is used to great advantage during pulling and racking cables and for moving heavy equipment about the vault. This feature has saved at least 50 per cent of the time formerly required for setting up to pull cable.

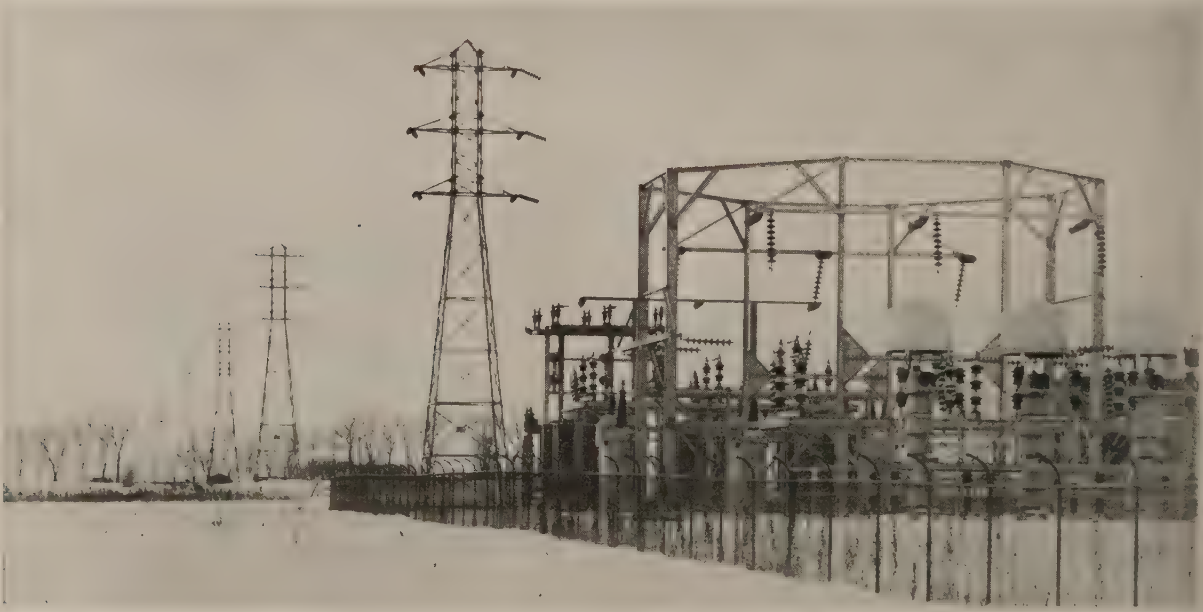
## Octagonal Frame Permits Various Bus Arrangements



On the Northern States Power Company's system as well as other properties of the Byllesby Engineering & Management Corporation may be seen this type of switching structure. It has the advantages that lines can be brought in and dead-ended from any direction and still permits the buses to be run in directions most desirable for the switch and transformer layout.

# Void Formation in Cables

### Quality of insulation apparently not limited by present materials. Relations between contraction, viscosity and compound temperature

By W. N. Eddy

*Director Electrical Research Laboratory*
*Simplex Wire & Cable Company, Boston, Mass.*

Cable research has established that premature failure of high-voltage cables is usually caused by the presence of voids within the impregnated paper insulation. Under sufficient stress these voids are ionized. Because of the resulting evolution of gas within the voids, the formation and ionization of additional voids may become cumulative, resulting in failure of the insulation. The purpose of this article is to show the influence on the void formation of the viscosity-contraction-temperature characteristics of the impregnating compound and to suggest that the insulation quality of cables for 25- to 75-kv. working pressure can be materially improved by a more general application of these fundamental relations.

Prior to the saturation or original filling of the paper with compound, all moisture has presumably been removed from the paper and its air content reduced to a low value. Complete submersion of the insulation for a suitable time at a suitable temperature in a properly dried and "degassed" compound follows. Economy demands a saturation period as short as may be required to accomplish the purpose. The necessary penetration time depends principally on the compound pressure, the paper "air resistance," compound viscosity and to some extent the nature of the compound. The nature of the paper fiber is practically negligible in its influence as compared with the predominating importance of the air resistance characteristics.

TABLE I—RELATIVE PENETRATION OF DIFFERENT COMPOUNDS AT THE SAME VISCOSITY

All tests at atmospheric pressure five minutes in duration, using 7-mil manila paper, of air resistance = 14 sec./300 cc. Viscosity of each compound at time of test, 66 seconds Saybolt.

| Compound | Penetration in Mils | Penetration in Per Cent of Rosin Oil Blend |
|---|---|---|
| Blend of rosin and cylinder oil | 140 | 100 |
| Transformer oil No. 1 | 133 | 95 |
| Petrolatum No. 3 | 126 | 90 |
| Cylinder oil No. 2 | 119 | 85 |
| Cylinder oil No. 4 | 119 | 85 |
| Petrolatum No. 4 | 112 | 80 |
| Cut-back petrolatum No. 1 | 105 | 75 |
| Cylinder oil No. 3 | 98 | 70 |
| Rosin oil No. 1 | 98 | 70 |

In general, the penetration and viscosity charts and table indicate that the selection of a proper saturating procedure is almost entirely dependent on certain physical characteristics of both paper and compound. No change in any of the related variables should be made without considering the effect on the others.

At atmospheric pressure and room temperature a typical insulating oil can take into solution air equal to about 10 per cent of the oil volume. The solubility of air in such oil increases in direct proportion to the absolute pressure. On this basis, if the oil is properly treated before the saturation, its air content should be below 0.3 per cent at the beginning of saturation. In like manner, the residual air in the insulation at the start should not exceed 2 per cent of the space to be filled with compound. Therefore, if no air is admitted during

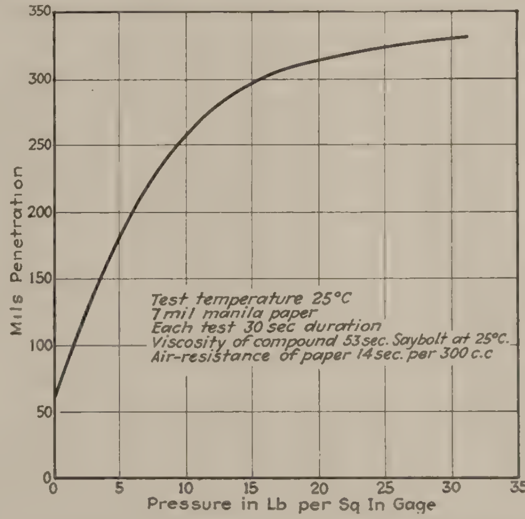


*Fig. 1—Effect of pressure on compound penetration*

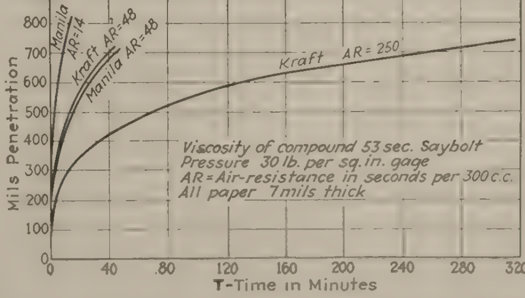

*Fig. 2—Compound penetration through wood pulp and manila papers*

At 600 mils the penetration through the wood pulp is 4,300 per cent slower than with manila. The two middle curves indicate that the difference between the other curves is due to air resistance rather than to type of fiber. All the penetration-time curves are approximately parabolic with an exponent of about 0.26.

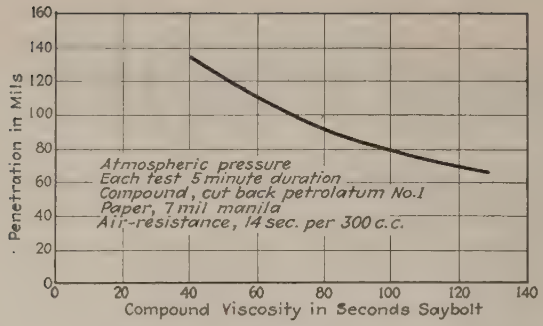

*Fig. 3—Effect of compound viscosity on penetration through manila*

While the viscosity of any compound can be decreased by raising the saturating temperature, this method of improving penetration is limited by the increased deterioration of the compound at the higher temperature. Both viscosity and deterioration at the saturating temperature are important factors in selecting an impregnating compound.

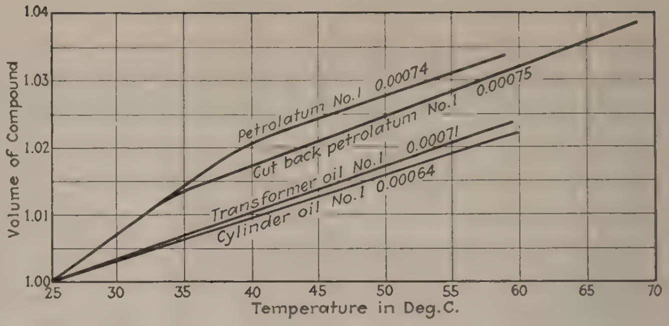

*Fig. 4—Volume-temperature characteristics of typical compounds*

Change of volume with temperature is approximately uniform for all the compounds above 40 deg. C., but the rate of the two petrolatums doubles at their approximate solidification temperature and maintains that rate down to 25 deg. This disadvantage is but slightly improved by "cutting back" with a thin oil. The contraction is more than ten times that of paper, copper or lead.

saturation, the air content of the insulation should not exceed 2.5 per cent of the compound volume. If the compound is put under air pressure during saturation the air content of the insulation may reach 10 per cent or more, but need not exceed 3 per cent if done properly. It therefore seems a reasonable assumption that voids will be present at the end of the saturation only if the time of saturation is insufficient for complete penetration. All air values are at atmospheric pressure.

### Contraction During Cooling

After saturation the compound temperature and hence that of the cable is lowered. As the compound cools it decreases in volume, and more compound must work in through the insulation from the excess compound around the cable to prevent the formation of voids in the insulation. The volume-temperature characteristics of a few representative compounds are shown in Fig. 4.

While no complete curves can be given at this time for compounds containing rosin or rosin oil, determinations of the total expansion between 25 and 80 deg. C. indicate that such compounds show about 10 per cent less contraction than those without rosin.

As the compound cools, it also gradually stiffens, or increases in viscosity. Some viscosity-temperature curves for several typical compounds are shown in Fig. 5. From these data it may be concluded that when the shrinkage is more rapid than the movement of the compounds through the insulation voids will begin to form in the insulation, that when it is not more rapid no voids will be formed, and when it is less rapid any voids already formed will be decreased in size.

It is difficult to see how the air content of the compound, if it does not exceed 10 per cent, can do more than merely fill the voids when they form. In a cable of modern impregnation the air content of the compound should not in itself be the cause of void formation.

The denseness of the paper insulation apparently influences void formation through segregation of compound and movement of compound. If the voids are caused by compound shrinkage, the void content per unit volume of insulation will be directly proportional to the amount of compound per unit volume. If relatively large interstices are included in the paper arrangement, the segregation at these points will produce a void formation that may easily be double that throughout the remainder of the insulation, as the ratio of compound to total insulation is usually around 50 per cent. Under some conditions, the only voids present may be at these points. While such segregation may be caused by excessively loose taping, probably the most familiar instance is along the inside edges of the fillers in three-conductor belted cable. This is the usual location of *X* when found. Incidentally, this suggests that the well-known greater ionization and shorter life of three-conductor belted cable compared with single conductor or shielded three-conductor is due to the same cause. If so, this constitutes the principal limitation of three-conductor belted cable for other than medium voltages.

Decreased denseness of paper insulation should also favor void elimination. This can be accomplished by looser taping and by decreasing the air resistance of the paper, but with a realization that the latter method

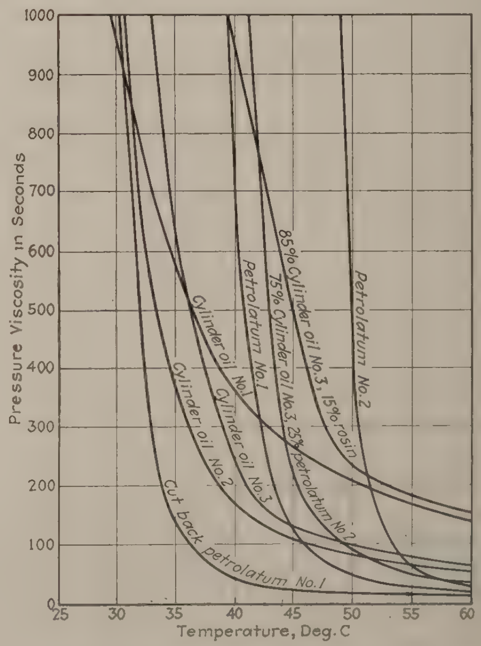

*Fig. 5—Viscosity-temperature curves for typical compounds*

While none of these compounds plotted shows a definite solidification temperature like water, their viscosity increases very rapidly below the critical temperature, which is generally more definite with petrolatums than with cylinder oils.

appears more favorable, since the former is liable to cause undue concentration of compound.

Fig. 6 shows the influence of the viscosity and contraction characteristics of Figs. 5 and 4 upon the formation of voids during the cooling period. While these curves have certain definite limitations, they afford an interesting comparison of types of compound and cooling rates. The cooling curves *A* and *B* were assumed as reasonably representative of a high and low rate of cooling respectively. In the factory tanks the cooling rate can be somewhat controlled by water jackets in the tank walls and circulation of compound through cooling coils.

TABLE II—VOID VOLUME IN COMPLETED CABLE

All weighings made after overflow of compound had ceased.
All cable saturated with cut-back petrolatum No. 1

| Test Temperature in Deg. C. | Compound Expelled from Sample in CC. | Volume of Voids at 25 Deg. C in Per Cent of Total Compound Volume |
|---|---|---|
| 3/350,000 circ. mil $\frac{10\text{x}5\text{ in.}}{32}$ | | |
| 40 | 0 | |
| 60 | 7.78 | 2.4 |
| 80 | 15.50 | |

| 40 | .31 | |
| 60 | 1.17 | |
| 80 | 1.19 | |
| 100 | 1.16 | 1.0 |
| 1/750,000 circ. mil $\frac{24\text{ in.}}{32}$ | | |
| 55 | 10.4 | |
| 68 | 5.5 | 0.9 |

The compound shrinkage curves were derived by combination of the cooling curve with the volume-temperature relations of Fig. 4, and the compound movement curves were derived by combination of the cooling curve with the viscosity-temperature curve of Fig. 5. (See Appendix I.)

Comparison of the *A* and *B* curves of Fig. 6 indicates the danger of selecting the rate and duration of the cooling period without proper consideration of the compound viscosity and contraction. It is evident that the acceleration of compound penetration or movement by pressure (Fig. 1) is applicable to the cooling period as well as saturation. The obvious limitation of the curves of Fig. 6 is that the compound movement is based on viscosity tests rather than movement through actual insulation. While this is no objection when merely comparing compounds or cooling curves, it prevents direct application of the curves to practice. Thus, while Fig. 6 shows *A*1 to eliminate voids at 200 hours, against 400 hours for *A*3, the real significance of the comparison is that for that particular cooling rate and the same type of cable *A*1 should eliminate voids in half the time taken by *A*3.

### DETERMINING VOID VOLUME

A possible simple method of determining void volume without the laborious collection of movement data through insulation is to ascertain the void volume resulting from a certain compound and a known impregnation procedure, and to adjust the scale of the movement curve so the height of the shaded area will agree with the known void volume. Then if the contraction and the movement scales are kept relatively the same, and if the movement of the compound through the insulation is assumed proportional to its movement through the viscosimeter, the curves should represent actual conditions, no matter what the compound or cooling rate. However, any change in the type of cable or size of cross-section would necessitate another void determination and adjustment of the movement scale.

A simple and direct method of void volume determination suggests itself: A short sample, say 12 in., of the completed cable with one end sealed and the other open is kept in a vertical position with the open end up at, say, 40 deg. C. until compound has ceased to flow from the open end. The procedure is then repeated at, say, 60 deg. C., etc. The compound overflowing at each temperature is weighed and the void volume is readily calculated from these observations. The method has several sources of error, but seems worthy of consideration. A few preliminary determinations are given in Table II. (See also Appendix II.)

The difference shown above between single and three-conductor cable is of incidental interest, in connection

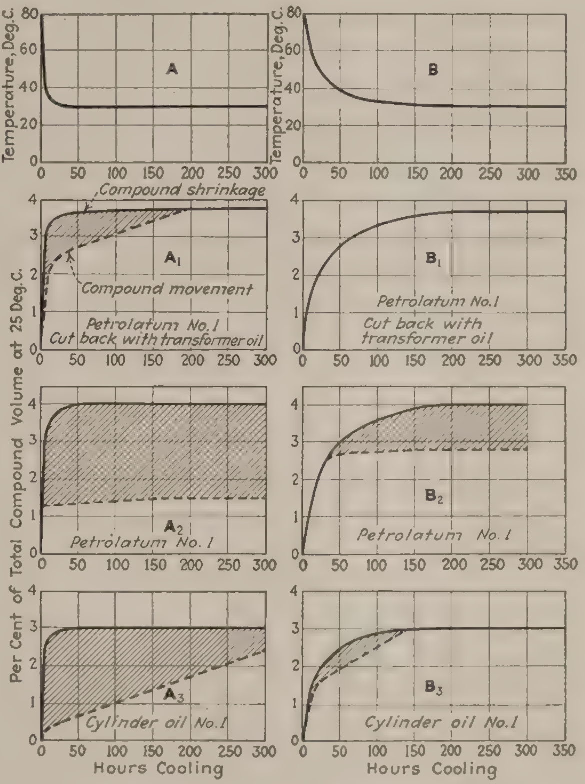

*Fig. 6—Relative shrinkage and movement of three compounds at two rates of cooling*

As the solid curves, subscripts 1-3, represent the compound shrinkage and the dotted curves the compound movement in through the insulation, voids must form whenever the latter is below the former; i.e., whenever the movement lags behind the shrinkage. All shaded portions represent the presence of voids, the difference between the curves at any particular time being the void volume at that time. With the cooling rate *A*, while the shrinkage of the cut-back petrolatum *A*1 exceeds the movement at first, the shrinkage ceases at constant temperature, while the movement continues, finally overtaking the shrinkage and filling the voids at 200 hours. If the cooling period were terminated when the temperature become constant, there would be a void volume of 0.4 per cent of the total compound volume, while a continuation of the cooling period at constant temperature would eliminate the voids.

The greater stiffness of the petrolatum *A*2 at the lower temperatures makes its movement so slight in this range that no reduction in void volume is appreciable, regardless of the length of the cool. This cable should contain materially more voids than *A*1.

The cylinder oil *A*3 shows the effect of its flatter viscosity curve (of Fig. 5). Its movement, though relatively less at first, exceeds *A*1 at 30 deg. C,, with the prospect of ultimate void elimination.

The effect of the slower rate of cooling, *B* curves, is that the void formation is materially decreased with all three compounds, although the petrolatum, *B*2, still shows no indication of eventual void elimination. It is clear that the cut-back petrolatum and the cylinder oil could be stopped as soon as their temperature became constant.

with the common experience as to ionization and life. All agree in indicating more voids in the three-conductor cable, probably because of the filling.

When cable cools in service the relation of compound viscosity and contraction in forming voids is much as shown in Fig. 6, with the following exceptions: (1) The rate of cooling in service may be more rapid than in the factory on account of the smaller mass of compound involved, which gives greater void formation; (2) even voids existing only during cooling mean ionization and incipient trouble; (3) coolings after lead expansion are more liable to produce voids because the total volume within the sheath has been increased without increase in compound volume, and (4) sheath expansion, by lowering the pressure "behind" the compound, may materially decrease the inward movement of the compound and therefore cause void formation in the interior of the insulation.

Thus it appears that it is insufficient to select a combination of compound, rate and duration of cooling, etc., that will result in freedom from voids after the cooling. The ability of such a cable to pass acceptance tests would not guarantee satisfactory life. It is also evident that whatever the operator can do to decrease the range and abruptness of temperature variations will reduce his cable failures, and that the use of a thin oil in joints under pressure should reduce the liability of void formation in the cable.

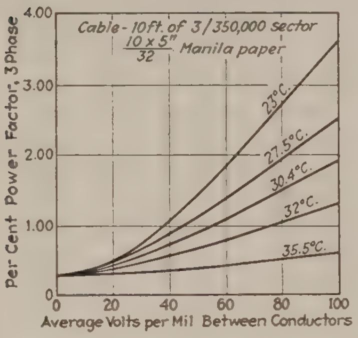

*Fig. 7 — Power-factor-voltage curves of three-conductor cable*

Void conditions improved by increase of temperature

### Test Data Reconciled by Variation in Compounds

It is of extreme importance to determine the quality of cable without subjecting several thousand feet to several years' service. The most important tests of this kind in present use are the overvoltage life test and the power-factor-voltage or ionization test. The former has been found to be a reasonably reliable indication of cable quality, but has the disadvantage of being slow and destructive to the cable tested. The second is reasonably quick and is not destructive, but does not always agree with the life test.

The principal differences between such tests and service conditions are (a) the test temperature changes are less severe; (b) the test cable is usually open at both ends. These reduce the chances of voids being produced during the test, especially by expansion of the sheath.

Application of the above viscosity-contraction relations to these tests is of considerable aid in properly interpreting them. For instance, these relations would indicate that relatively small temperature changes between 25 and 35 deg. C. should have material influence on the voids in the insulation and, therefore, on the ionization and life tests.

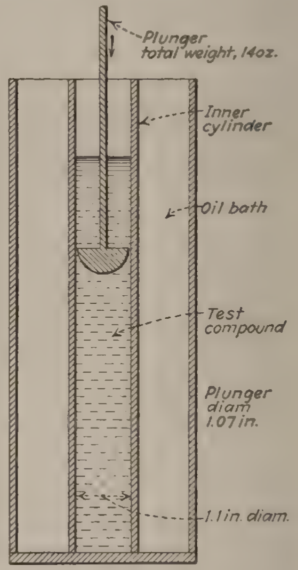

*Fig. 8 — Viscosimeter for compound testing*

As no satisfactory equipment could be found for this purpose, this apparatus was developed. The inner cylinder was filled with compound and the outer chamber with an oil bath for temperature equalization. As the plunger descends by gravity the compound is forced up through the annular clearance between the plunger and the inner cylinder, and the plunger was arranged to energize a recording voltmeter at the end of its travel, permitting tests to be started during the day and completed at night without attendance.

The power-factor-voltage curves on three-conductor cable saturated with cut back petrolatum shown in Fig. 7 indicate that increase of temperature from 24 to 35 deg. C. materially improves the void conditions in the insulation.

In determining the effect of similar temperature changes on the life, it should first be noted that the actual insulation temperature of a so-called room temperature life test may be 35 deg. C. at a test voltage between two and three times the operating voltage. Table III gives some temperatures actually obtained.

The elementary viscosity-contraction-temperature relations suggest that a decrease of life test temperature of only a few degrees ought to decrease the cable life by increasing the void content. The figures of Table IV show that a decrease in temperature of only 5 deg. C. is often sufficient to decrease the life 30 per cent. It would be expected that this influence of temperature would vary for different compounds, according to their viscosity-temperature characteristic. While such tests are in progress no results can yet be reported. It is suggested that this may account, at least in part, for occasional disagreement between the ionization test and the life test, especially with cable of different compounds or manufacture. The life test temperature

TABLE III—REPRESENTATIVE TEMPERATURES OF OVERVOLTAGE LIFE TEST SAMPLES

| All Samples 10 ft. Under Lead | Deg. C. Ambient | Deg. C. Sheath | Deg. C. Conductor* |

## *Appendix I—Derivation of the Curves of Fig. 6*

The compound shrinkage curves were derived by combination of the cooling curve with the volume-temperature relations of Fig. 4. For any one time of cooling, the corresponding compound temperature given by the cooling curve was applied to Fig. 4 and the corresponding volume noted. By summation of the increments of volume change, the total shrinkage is determined as plotted in Fig. 6.

The compound movement curves were derived by combination of the cooling curve with the viscosity-temperature curves of Fig. 5. For any one time of cooling, the corresponding compound temperature given by the cooling curve was applied to Fig. 5 and the corresponding viscosity noted. The viscosity is given on Fig. 5 as the time necessary for a given volume of compound to flow through a given orifice. Therefore, the reciprocal of this figure should be directly proportional to the rate of flow (volume per unit time) of the compound. While this figure is not the rate of flow through actual insulation, it should be relative and, therefore, suitable for comparisons of compounds and cooling rates. A figure proportional to the total flow can be obtained from summation of the increments of the change in rate of flow. This represents the total movement throughout the period of cooling that is permitted by the insulation denseness and the compound viscosity.

Before this can be compared with the compound shrinkage as in Fig. 6, a proper proportionality factor must be determined. This was done by assuming a definite void content of 0.9 per cent after 50 hours of *A* cooling with the cut-back petrolatum. This is believed to be sufficiently representative for comparison of compounds and cooling rates. The same factor was, of course, used for all the other curves.

When the permissible movement as determined above was less than the shrinkage, it was plotted as the actual movement. When it was greater than the shrinkage, the actual movement was assumed equal to latter and so plotted on Fig. 6. It is physically impossible for the compound to move into the insulation faster than the compound shrinks.

## *Appendix II—Determination of Void Content of Completed Cable*

The figures given in Table II were determined by assuming that (1) the compound expansion and contraction follow the relation given by Fig. 4; (2) all overflow from the sample is caused by expansion of compound; (3) when the compound begins to overflow from the sample the voids are eliminated—filled by expansion. This, of course, will not be true if the air content exceeds 10 per cent.

While the exactness of the last assumption may be questionable, it will at least serve for a few preliminary comparisons.

Let $C_0$ = total cubic-centimeters of compound overflowing below temperature 1.

$\Delta C$ = total cubic-centimeters of compound overflowing between temperatures 1 and 2.

$V_1$ = volume of compound in sample at temperature 1 in terms of the volume at 25 deg. C.

$V_2$ = volume of compound in sample at temperature 2 in terms of the volume at 25 deg. C.

Both $V_1$ and $V_2$ are read off the curves of Fig. 4, knowing the compound and the temperatures.

Total volume of compound in sample

$$= \frac{\Delta C}{V_2 - V_1}$$

Expansion below temperature 1 =

$$\frac{C_0\,(V_2 - V_1)}{\Delta C}$$

Volume at beginning of overflow =

$$V_1 - \frac{C_0\,(V_2 - V_1)}{\Delta C}$$

Therefore, void volume at 25 deg. C. in per cent of total compound volume =

$$\left[\left(V_1 - \frac{C_0\,(V_2 - V_1)}{\Delta C}\right) - 1\right] \times 100$$

The void content in per cent of the total insulation will be approximately half or less of the figures given in Table II.

One advantage of this method is that the sample dimensions are not necessary, the only necessary determinations being the quantity of compound expelled and the temperatures. Determinations need only be made at two temperatures. Those given in Table II at additional temperatures are of interest in showing how closely the overflow follows the relation of Fig. 4.

may be 5 to 10 deg. C. higher than the ionization tests and the resulting influence on the void condition may be different for different compounds used in the samples of cables tested.

While the overvoltage life test is generally believed to give a reasonably reliable indication of life in service, the curves of Fig. 6 suggest that there might be some compounds that would be voidless in the cable at the constant temperature of the life test, but would form voids during the cooling periods experienced in service. In such a case, the life test would not give a reliable indication of the insulation quality. It may be found that the reliability of the life test can be improved by a suitable periodic variation of the temperature. In general, it is believed that further investigation of the life and ionization tests along these lines may add materially to the usefulness of both tests. It may even be found that the principal difficulty with the latter test is merely lack of proper interpretation.

### CONCLUSIONS

It has probably been noted that no attempt has been made to include in the above data any conclusive proof of the influence of the compound viscosity-contraction-temperature relations on the service of the cable or even on the overvoltage life test. Such proof to be conclusive must include extensive tests on cable comparing compounds, impregnating procedures, etc. As available data of this nature are not sufficiently complete to be conclusive, it has been thought best to omit them altogether. It can be said, however, that such data as have been collected to date, including several different compounds and impregnating procedures, confirm the suggested controlling influence of the above-mentioned compound characteristics on the insulation quality.

The question of rosin or no rosin in the impregnating compound has received considerable attention for years without any generally accepted conclusion being reached. It has been said that the principal advantage of a rosin content is that the compound is less easily displaced by the dielectric stress. If this is true, a properly saturated cable should need no rosin, since the compound could not be displaced anyway. This may be one reason why it is so difficult to get a conclusive story, either in favor of rosin or against it.

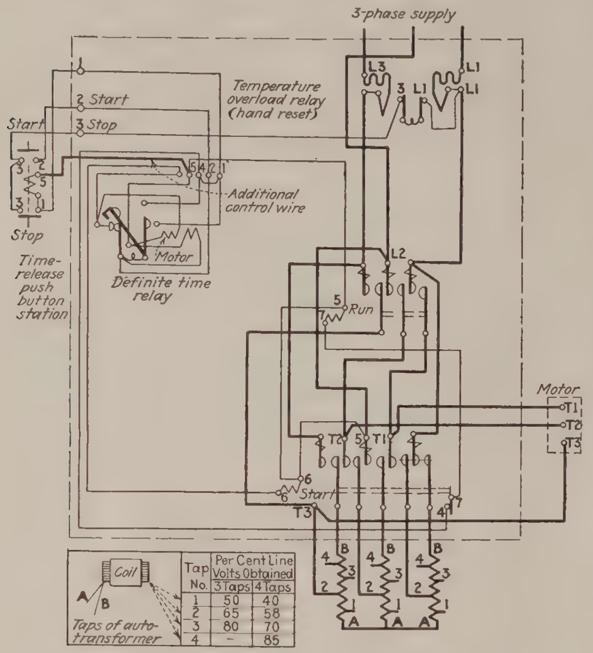
The test results given and discussed above suggest, in general (1) that the quality of impregnated paper insulation is not yet limited by the type of materials in use; (2) that material improvement in insulation quality can be obtained by more proper application of the fundamental relations between the contraction, viscosity and temperature of the compound, and (3) that, therefore, these relations should be more completely determined by research work.

It is believed that a more general understanding of these relations among all concerned will go far toward rationalizing the manufacture and use of impregnated paper insulation.

# Time-Delay Undervoltage Device Minimizes Interruptions

By L. C. Hardesty
*Industrial Control Engineering Department*
*General Electric Company*

A DEVELOPMENT in push-button stations controlling standard magnetic starters and incorporating a time-delay element makes it unnecessary to add time-delay attachments to the starters themselves. The application of such a station to the reduced-voltage type of starting compensator requires consideration of several factors. If a connection is made, using the standard wiring of the compensator, and a voltage dip occurs, the compensator contacts will open, and, if voltage returns before the push-button station trips, the starting contactor on the compensator will close, and the compensator will go through the regular starting sequence, as it would if the motor were being started from rest.



| Tap No. | Per Cent Line Volts Obtained | |
|---|---|---|
| | 3 Taps | 4 Taps |
| 1 | 50 | 40 |
| 2 | 65 | 58 |
| 3 | 80 | 70 |
| 4 | – | 85 |

*Standard low-voltage automatic compensator equipped with time-release control*

The substitution of a standard time-release push-button switch for the usual start-stop type and the addition of but one control wire between the switch and the definite-time relay permits adaptation of standard automatic compensator to time-release characteristics.

This dropping back to reduced voltage on a voltage dip might, in some cases, be objectionable. The amount of inconvenience would depend on the compensator tap used and the amount of load on the motor. If the motor were driving one of a series of belt conveyors, and it should be thrown back on partial voltage, the speed might be reduced enough to cause a perceptible pile-up of material on the belt. In such cases, a slight speed reduction on the motor might be objectionable, but it is probable that, in the majority of instances, a slight speed reduction after a voltage dip would not cause any difficulty.

In cases of trouble, however, the standard automatic compensator can be used by adding but one control wire. The accompanying diagram shows the connections of standard low-voltage automatic compensator equipped with a time-release push-button station. If a voltage dip occurs, the "run" contactor will open, but if voltage returns before the push-button station trips, the "run" contactor will close again, putting full voltage back on the motor.

# Cable Sheath Troubles at Duct Edges

By C. H. Shaw
*Engineer Distribution and Installation Department,*
*New York Edison Company*

ONE OF the most common sources of trouble in the operation of underground cables is the abrasion of the lead sheath of the cables at the point where they emerge from the conduits in the manholes. The daily change in load results in a heating and a subsequent cooling of the conductors of the cable, which causes expansion and contraction that produces an abrasion at the duct edge usually at both ends of every cable section.

In existing systems, where adequate provision has not been made for taking care of the expansion of the feeder cables, it is a difficult matter to eliminate this duct edge condition. Many engineers of underground distribution systems have failed to realize that this abrasion is largely a function of the design and method of installation of the cables in the manholes. If the manholes are constructed of such a shape that an even movement of the cable is permissible during its expansion cycle and if the cables are trained and supported on the manhole walls in a proper manner there will be little or no cause for worry as to the condition of the cables at the duct edge.

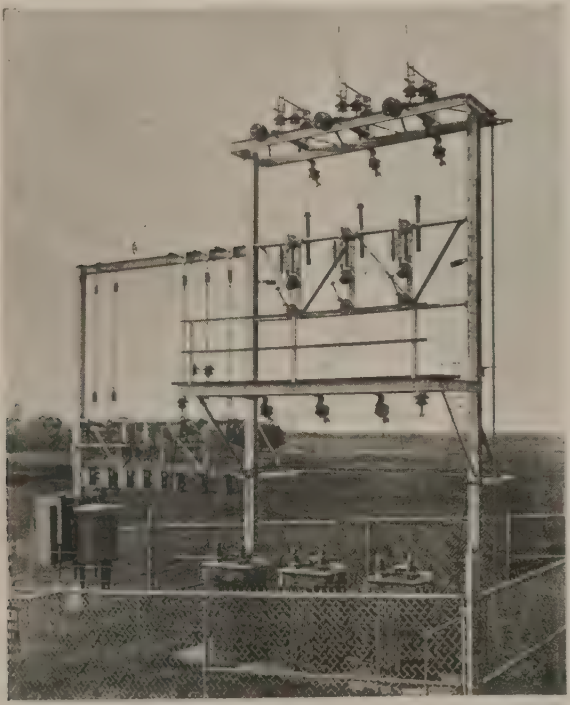
The following data have been prepared indicating the relatively insignificant importance of duct edge injury on one of the largest underground cable systems in the world, that of the New York Edison Company. On the system in question the amount of low-tension feeder cables has increased from 3,400,000 ft. at the end of 1922 to 5,200,000 ft. at the end of 1927. This cable is installed in conduits with an average length of approximately 200 ft. each, and therefore represents more than 55,000 duct edge exposures:

| Point of Trouble | 1922 | 1923 | 1924 | 1925 | 1926 | 1927 |
|---|---|---|---|---|---|---|
| At splice | 29 | 6 | 2 | 6 | 9 | 3 |
| Between splice and duct | 12 | 7 | 4 | 3 | 6 | 10 |
| In duct | 6 | 13 | 14 | 23 | 64 | 71 |
| At duct edge | 8 | 5 | 2 | 2 | 1 | 2 |

It will be seen that there has been an appreciable reduction in the number of troubles that have been located at the duct edge. This has been due to a continuous improvement in the general condition of the underground cable system as well as to the reconstruction of a considerable number of manholes that had been built in former years when the knowledge of cable operation was not as complete as at present and before the proper shape of manholes for this type of cable installation had been determined. Incidentally, the unusually large number of failures of cable in duct that are indicated in the above tabulation have been due to mechanical injury from sources outside the duct line, such as bull points, etc., and do not indicate any decrease in the quality of the cable insulation. In all of the years there have, of course, been some cases of mechanical injury included in the figures for trouble "in duct." Practically all of the cables described in the preceding paragraph have been protected with zinc fairleaders at the duct edge. It is probable that the average life of the cables installed in the conduit system exceeds ten years. It is probably impossible to determine in one month, or even in one year, that a new type of manhole design or method of cable racking is entirely satisfactory. There have been placed on the market for the past few years a large number of different types of duct edge protectors. Their installation in existing systems would call for the reconstruction of the duct lines and the same results could be secured for a redesign of the manholes. In new conduit lines about to be constructed there is no need for the use of these devices if the manholes are arranged so as to provide adequate expansion space for the cables. If the manholes, in the ordinary parlance of the underground cable manhole, could be classified as expansion chambers, rather than as manholes, it is probable that much more attention could be given to providing for adequate expansion and contraction of the cables than has heretofore been provided in most underground conduit systems.

## Economy in Small Substation

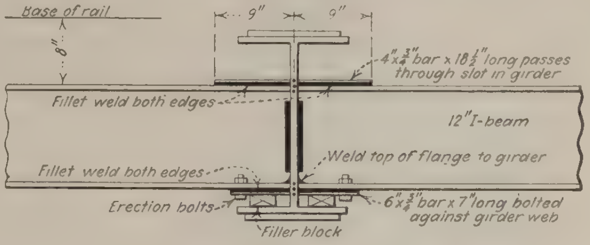
SIMPLICITY and low cost are the distinguishing features of this substation, through which the Wisconsin Public Service Corporation serves the village of Lena, Wis. The primary feed is at 13,800 volts and the secondary output is taken off by one 2,300-volt line and a street lighting circuit. The equipment includes three 75-kva. transformers and a 10-kva. street-lighting regulator. The meter is contained in the box at the left and the instrument transformers may be discerned mounted in the left bay. The use of fused cutouts in place of breakers is to be noted. The substation, with the exception of transformer and instrument equipment, was furnished by the Railway & Industrial Engineering Company.



*Simplified design reduces installation cost*

## Electric Welding Cuts Steel Bridge Tonnage One-Third

BY THE use of electric welding the amount of steel required in a Boston & Maine Railroad bridge 175 ft. long now being built at Chicopee Falls, Mass., has been reduced at least 33.3 per cent, according to Gilbert D. Fish, consulting engineer Westinghouse Electric & Manufacturing Company. The design for welding calls for but 80 tons of steel. More than half the saving is in reduction of connection material; only about 25 per cent of the joints have gusset plates, and these gussets are only about one-fifth as large as those needed for riveted joints. Most of the remaining saving is about equally divided between reduction of tension members due to eliminating allowance for holes and reduction of stringers due to continuity through floor beams. No channels were used. Slot welds $\frac{1}{2}$ in. square in section connect the members to the gussets, and 1.5 in. of one slot is about equivalent to one $\frac{7}{8}$-in. rivet in single shear. Triangular fillet welds assist the slot welds and the value of a $\frac{3}{8}$-in. fillet weld is about one-half that of a $\frac{1}{2}$-in. x $\frac{1}{2}$-in. slot weld.



Base of rail
8"
9"
9"
4"x$\frac{3}{4}$" bar x 18$\frac{1}{2}$" long passes through slot in girder
Fillet weld both edges
12" I-beam
Weld top of flange to girder
Fillet weld both edges
Erection bolts
6"x$\frac{3}{4}$" bar x 7" long bolted against girder web
Filler block

*Typical welding of stringers to floor beam*

The shear connection for the floor beam is a triangular butt weld with $\frac{5}{8}$-in. x 18-in. minimum section. At the end joints the chord tension is developed by butt welding of flanges only and by slot and fillet welds at the splice plates. Among other welding features is the typical connection of stringers to floor beams illustrated herewith. Welding quantities are as follows:

Span of each truss, 134 ft. 8 in.; width center to center of trusses, 17 ft.; number of tracks, one; height center to center of chords, 24 ft. 8 in.; estimated man-days riveting, 50; saving in tonnage by electric welding under E-50 loading, 40 tons.

| | Shop | Field | Total |
|---|---|---|---|
| 38-in. triangular fillet, feet........ | 308 | 562 | 870 |
| Butt and slot welds, cubic inches... | 88 | 450 | 538 |
| All kinds of welds, cubic inches.... | 348 | 921 | 1,269 |

Two welders are employed for all work in shop and field, using a 200-amp. Westinghouse motor-generator set on a truck. The total estimated man-days of welding required on this job is 50. Direct-current welding only is employed. It is expected that this bridge and others to be welded in future will prove somewhat more permanent than riveted ones, because the immovability of the joints removes the chief cause of fatigue. Although weld metal is less ductile than rivet steel, a properly designed and executed welded joint should have greater endurance under stress reversals than a good riveted one, because in the case of the latter the connection members and rivets are subject to slight motions back and forth, frequently beyond the elastic limit. Another factor favoring long life for welded joints is their smoothness and absence of rivet heads, with corresponding ease of painting and lessened tendency to corrode.

# Pointers from Alex Dow

### Points made in address before Midwest Power Conference in Chicago hit at misconceptions as to utility affairs. Costs of business and business policy outlined

THAT a wise blending of technics and economics is essential to the success of the power industry was the theme of an address made recently by Alex Dow before the Mid-West Power Conference held in Chicago. Various phases of the problem of capital costs in relation to central-station operation were discussed—not merely in the abstract, but with ample illustration drawn from the experience of the Detroit Edison Company. After discussing some of the more general problems, such as the presence in the industry of a few financial exploiters seeking only personal profit, Mr. Dow turned to certain aspects of the problem of maintaining earnings at a level corresponding with the growth in capital investment:

"The response to good economics in the power industry becomes translated into terms of bigger power earnings. If we did not sell the 800,000,000 kw.-hr.—practically without exception the people who bought that 800,000,000 kw.-hr. last year were concerns that were financially, technically and mechanically able to make their own power and would have done so if the rate had not been a factor—had we not sold this power out of the total of 1,800,000,000 kw.-hr. that we did sell, we would not have been able to give such good service or such low-rate service to other classes of customers. The actual cost would have increased in such a manner that the whole of the general public, right clear down to the smallest kind of a residential customer, would have been served less well, less liberally and almost certainly at higher cost. There would have been overhead that would have had to be distributed that wasn't necessary and wasn't brought in by this increased business. These sales were to some 360 customers; only 370 accounts to keep open, all of them prompt and payable, all of them very simple, all of them buying untransformed current and taking care of their own transformation and conversions, requiring nothing from us but occasional engineering advice, and having that given to them as honestly as we knew how. The addition of the production has meant to us a big economic advantage and that economic advantage has not been grabbed by us, but has been distributed as it ought to be, over our entire business, to the benefit of our public at large. And this business, at the lowest average rate, has always carried a good share of the profit and in many years has been the most profitable business.

#### Policy Toward Different Classes of Service

"Now, I want to point out to you that the economics of the power industry are very much affected by your policy toward the different classes of service. If you are going to serve your home community; if, in point of fact, you are going to furnish exceptional service at an acceptable price to all classes of your industry, you not only have the duty laid upon you to have your rate schedule so co-ordinated that there is no evidence and no sign of discrimination, but you have to meet the problem of dealing with the big man who can make his own current and you have got to sell to him at a price that is below his legitimate costs. He will break even with you; if you will sell to him at the price at which he thinks he can make it himself, as a rule you can do business. You cannot, of course, go trading with each individual man, and therein comes one of the difficulties of rate schedule making. If you want that backlog, if you want that increased production, if you want that justification for larger power plants and large and efficient units, you have to handle it at a rate that will be essentially competitive with what the best kind of private plant can produce the service for. You do not need, as a rule, to go below it, because the intelligent manufacturer, who does not want to run a power plant unless he has to, will give you as much as the service will cost him and give it willingly.

"There is just one objection about that. If he had to have an increase in power and he were setting up his own plant and being served by his own plant, he would begin to think about it at least six months ahead and arrange to finance it, whereas with service like ours if he wants an increase of power, he wants it yesterday and kicks because he didn't get it and we have to try to serve him just that way. That means that we have to guess what the service will require. We have to develop two or three years ahead.

#### Case of the Small Customer

"Now, jumping for a minute to the other class of service, the smallest, most troublesome service, the small consumer—he amounts to a great deal. In our district we don't serve him nearly as much current as we would like to serve him, and we know he is buying more every year, or I should say she is buying more every year. For, after all, it is the woman in the house who controls that sort of thing. Actual earnings from that source in the last calendar year were nearly $11,000,000, and that is a nice item, amounting to about 23 per cent of our total business. But that is got from a great multiplicity of customers, say over 400,000, and it is troublesome work. It is work in which the production cost and the transmission losses are almost negligible."

Mr. Dow pointed out that the cost of fuel is relatively small in relation to some other items. "All transmission losses, all transformation standby losses, such as idle losses in the multiplicity of line transformers; the actual generating of the necessary transmission losses, plus the actual service metered to the customer; the average residence customer, do not require one-half ton of coal per annum, whereas the mere keeping of the account open at the present market rates for coal, the metering of the service, putting in a meter, the reading of the meter, the maintenance of the meter, the checking up every two or three years on the accuracy of the meter, which is imposed upon us by the public utility regulation; the following up of collections, the rendering of bills, the providing of convenient places where the bills can be paid, all that sort of business costs us roughly three times as much as the fuel.

"Of course, there is little economic back-kick from that. If you are going to benefit the ultimate consumer, who is ultimately, of course, the man who consumes service in his house, if you are going to benefit him by getting cheap power at the expense of the general taxpayer, you are barking up the wrong tree. If our fuel costs were wiped out altogether and the fuel costs given to the residential customer; in other words, if we could allocate our coal costs and collect from a beneficent government at Washington that proportion of the coal bill that represented service to the small consumer, the residence consumer in particular, if we could do that, we would be able to cut that rate 8 per cent. We know that one way to bring down the residential service rate is to encourage

its use, because it is the failure to use the large investment that you must make for service when it is first installed, service afflicted with what we have for convenience called a dispersion factor; it is the difficulty of getting sufficient use of the investment that is the real limit upon the rate. If the use were doubled, the investment would not be doubled, because the form of the load curve would always of necessity be altered in a beneficial way. And that increased use is the real economic answer to the problem of serving the small consumer."

### Financial Exploiters on Wane

In the course of his address Mr. Dow also discussed the utility business from the point of view of a utility executive interested in proper methods of financing and operating properties. Some of his very pertinent comment is as follows:

"We still have with us the financial groups, to whom, especially to the newcomers in the industry, the industry is merely one of many means to make money. In other words, they measure the success of a public utility service by its contributions to their personal or group coffers, by the emoluments which they receive, directly or indirectly, by the opportunities for financial exploitation, and so on. We suffer from the activities of these groups. It is true that most of them have butted in and it is true that if they live long enough with us they either learn differently and behave in a better way or they get, metaphorically speaking, their necks broken. But we can't always be educating the people who butt in to our business.

"I have observed that in a great many recent cases the financial grabbing that has been found fault with has come from people or groups whose attitude toward public utility service at large is that of the attitude of the exploiter, the man who says, 'This thing can be dealt with thus and so, and I can close out the account with a handsome profit.'

"Now, so long as profits can be made and so long as the rules of the game make it possible that these profits may be very large and still stay inside the law, just so long will we have these raids upon us. Now, when these people, as happens occasionally, get out with a loss, a much-needed lesson is taught, and those of us who remain in the industry have a chance to clean up the mess. But there is a limit to all these things, and I am not so sure but that one of the byproducts of recent and present public interest, very much overstimulated, of course, by the political gentlemen who want to advertise themselves, will be more caution on the part of these exploiting groups.

"Present laws, without any particular assistance from legislative bodies, can be used to deal with the worst offenders. And the steadying of the utilities; that is, the forcing of them into common action, is very helpful in avoiding this kind of economic disturbance, a disturbance which results inevitably when the management of a big public service is in the interests of profit making only."

## Sign Exhibit Creates Sales

By R. B. Brown, Jr.
*Illuminating Engineer*
*Edison Electric Illuminating Company of Boston*

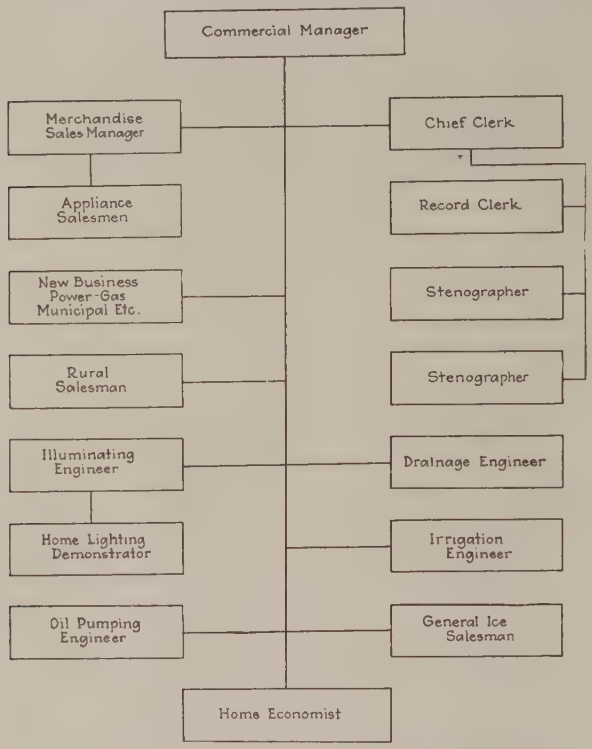
FIFTY-SEVEN electric signs with an aggregate connected load of 120 kw. were sold in the Boston Edison territory last fall during a six weeks' series of electric shows held by the company in suburban cities and towns. A total of 114 active prospects for sign business was also the fruit of the displays, and the estimated merchandising value of the signs to their manufacturers was approximately $25,000. The added revenue to the Edison company from the load represented by these 57 signs is estimated at about $8,000 a year, assuming an average run of four hours a night. The cost of the exhibit to the company was, roughly, $1,000 for the six weeks.

Two edison employees were in attendance practically all the time, the display being open to the public daily from 2 to 10 p.m. About 30 manufacturers of electric signs participated, and most of these were the owners of local sign plants, whose products thus became familiar to visitors to the shows as neighborhood commodities. The sign manufacturers co-operated by furnishing signs for the exhibit, but were put to no other expense than the cost of transportation of their products to and from the shows. Three or four manufacturers' representatives were also in regular attendance at the booth.

*Fifty-seven electric signs were sold by massed display in six weeks*

# A Flexible Commercial Department Organization

IN CARRYING out the sale of electric service to nearly 1,800 different communities, located in states from Maine to the Gulf of Mexico, the subsidiary companies of the Middle West Utilities Company naturally require a somewhat flexible sales organization. Local conditions differ in the various communities and the relations of local commercial departments with the commercial department of the Middle West Utilities Company are such that the local sales department is free to plan and carry out its sales program independently.



*Suggested organization chart for subsidiaries of Middle West Utilities Company*

The varied types of territories served are indicated by the provision for oil pumping, drainage and irrigation engineers in some departments.

With the view to providing a basis for building up a department to meet these local conditions, C. J. Eaton, commercial manager of the Middle West Utilities Company, has suggested the tentative form of commercial organization shown in the accompanying illustration. It is not intended that local departments shall be set up rigidly along these lines, but in so far as conditions permit the department will be patterned after the suggested organization.

Where a group of communities are so located geographically that sales programs can be directed and conducted from a central office the commercial department for this group is built up under the supervision of a commercial manager whose headquarters are at the general offices of that particular subsidiary. Primarily, the relations of these local commercial departments with the commercial department of the Middle West Utilities Company are such that the latter acts in an advisory and consulting capacity with the operating company in promoting the sale of electric service. Mr. Eaton states that he has found that a certain amount of standardization has made for economy and efficiency in the operation of the local departments, but such a standardization should not be carried too far as it would tend to hamper and discourage independent initiative as well as set up, in some cases, a form of organization not at all suited to the local situation.

# Electric Heat in Industry

A VALUABLE educational instrument for promoting the development of industrial electric heating has just been made available to the electrical industry. Through the combined efforts of the national industrial heating committee of the N.E.L.A. and the Detroit Edison Company a five-reel motion picture film, "Electric Heat in Industry," has been made and is being released by the committee on either a sale or rental basis.

This film, which is 4,500 ft. long and requires about 50 minutes to exhibit, covers all of the principal electric heat-treating applications, enameling, steel melting, and so forth. It has taken in nineteen different industrial plants and shows the actual operation of the latest electric heating applications installed in these manufacturing plants to effect refinements and economies in production processes. The film has been stripped of all non-essentials and the captions have been written with a view to brevity, but emphasizing the benefits to the user through savings in production costs and increased profits because of improved quality, reduction of spoilage and greater uniformity.

For the power company this film will make it possible to visualize to industrial customers what electric heating is accomplishing in other industries throughout the country. For the industrial plant which has a heat-treating problem the film will help to show how this problem has been solved elsewhere or suggests a possible improvement over the existing process.

The original picture was taken under the personal direction of H. J. Hall of the Detroit Edison Company and represents several months of intensive planning and negotiation with industrial plants before final releases could be secured. It was first shown publicly at the meeting of the American Society of Steel Treaters in Detroit last fall under the auspices of the N.E.L.A. industrial heating committee. Since then it has been exhibited at a number of other meetings and the film has already gained for itself an international reputation. Requests have been received from England and other European countries for prints of the picture.

The film is now complete and Walter H. Sammis, chairman of the N.E.L.A. national electric heating committee, has arranged schedules whereby positive prints can be purchased outright or it can be rented by power companies for a limited number of showings.

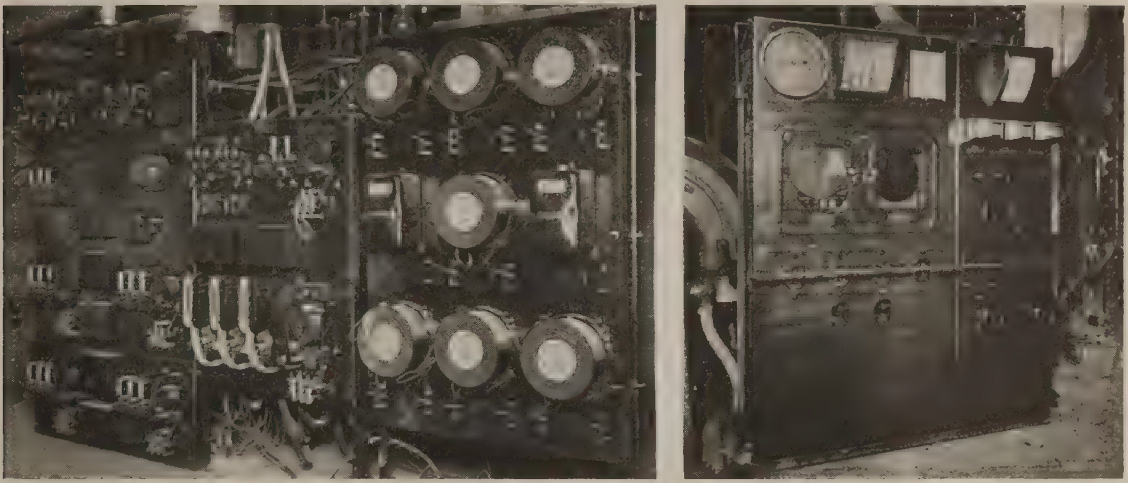
Proceeds obtained from the sale and rental of the film will be used in part to pay for the cost of its production and in part to keep the picture up to date by the addition of views of new applications as they are made from time to time. From expressions of opinions of those who have seen the picture it will prove a highly valuable means of promoting electric heating, and there are already a number of requests for showings before industrial and engineering organizations. In addition the film has been very useful in showing power company employees the extent of development of this class of load.

# Control of Boiler Auxiliaries

## Nature of operations that had to be controlled in running pulverized-coal-fired, water-walled, well-type furnaces at Buffalo and type of signaling and interlocking adopted

By W. S. Martyn

*Junior Engineer Buffalo General Electric Company, Buffalo, N. Y.*



*Control equipment for boilers in River station and heating station of Buffalo General Electric Company*

IT WAS with the thought in mind that the Charles R. Huntley steam plant of the Buffalo General Electric Company was to function mostly as a standby station that pulverized-coal-fired boiler equipment was bought.

The steam-generating equipment consists of four B. & W. cross-drum boilers, each containing 12,515 sq.ft. of heating surface, not counting the 7,100 sq.ft. in the integral superheater. This lies between the horizontal circulators and the main bank of tubes, so that the headers form a part of the third-pass baffle. The furnaces are of the Fuller-Lehigh well type, inclosed on all four sides by water walls covered with Bailey alundum blocks, which add an additional 2,044 sq.ft. of heating surface. Each well is 15 ft. 7 in. square below the burner line, but the two side walls fall away above the burners so that the furnace above this line is 24 ft. 3 in. x 15 ft. 7 inches.

The fuel-burning equipment takes coal from the green coal bunkers, located above the main boiler room aisle, through two 20-in. conductor pipes to a Richardson automatic scale, whence it empties into a small receiving bin. This bin serves the double purpose of regulating the flow of coal from the scales and holding a slight reserve to protect against minor scale troubles. From here the coal is fed to each of the two mills serving the individual boilers by two drag-chain feeders. The mills are of the vertical, air-separation, ball type, so designed that the induced stream of air rises over the grinding zone, carrying the pulverized coal along in suspension. This mixture passes through the exhauster and is then introduced into the furnace through two Calumet burners.

There are four burners per furnace, one in each furnace wall. The four flames impinge upon one another, augmenting the turbulence produced by the method of introducing the secondary air through ports at both sides of the burners. Such turbulence gives rapid combustion, which is completed well below the boiler tube bank. The gases, after three passes through the boiler, are led through a Foster economizer having 9,600 sq.ft. of surface and then discharged to the stack by a double inlet Sturtevant fan.

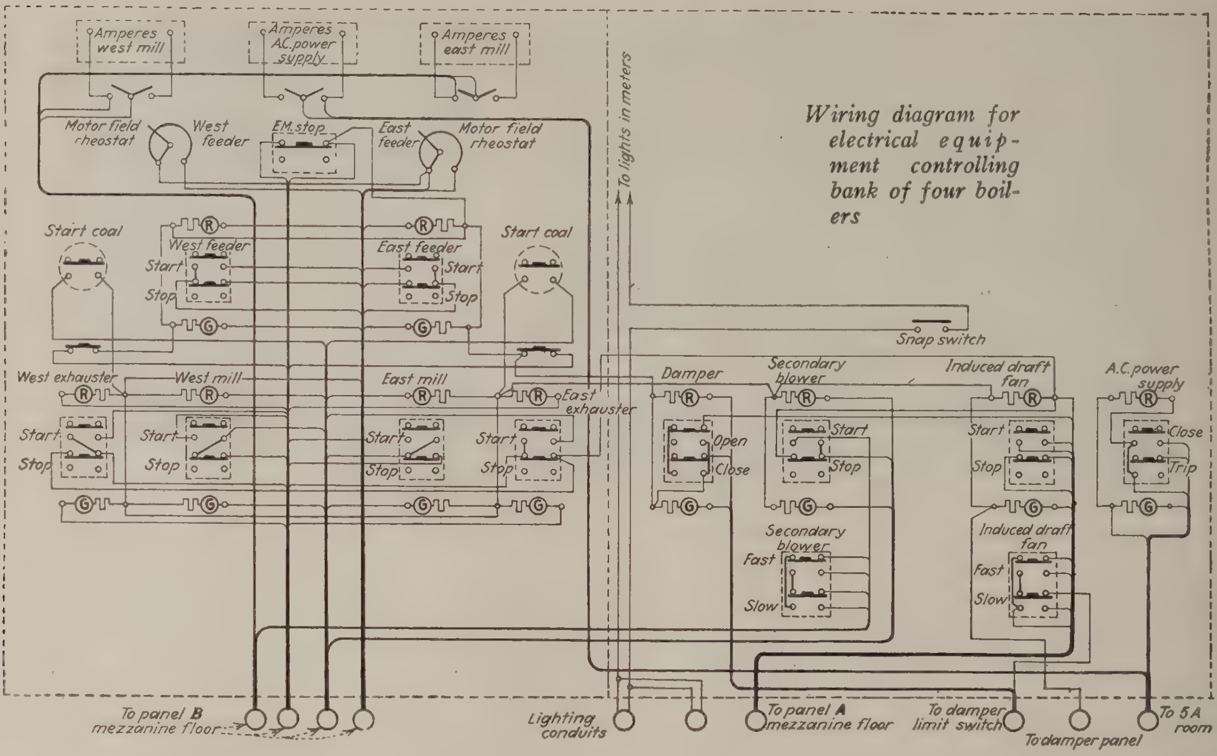
While it was conceded that small turbines would meet the requirements of the boiler auxiliaries, afford a comparatively wide speed range and develop a smooth speed curve, they were passed up in favor of electric motors because of the complications of piping, control, etc., and the difficulty of maintaining a heat balance.

It was deemed best to standardize on induction motors for auxiliary drives on account of the complexity which would arise were part of the plant's auxiliaries on the alternating-current system and part on direct current. For the same reason and because of the greater cost of high-voltage equipment an extension of the 440-volt distribution system was made. The rule to keep everything alternating current was adhered to with one exception. That was the drive for the drag-chain feeders controlling the flow of coal to each of the pulverizing mills. Motors rated at 1½ hp. were required and it is necessary that they have at least a three-to-one speed range. Inasmuch as the power demand was small the easiest solution was to install a small motor-generator set large enough to supply direct-current motors.

All motors with the exception of those driving the mill feeders are wound for 440-volt, three-phase, 25-cycle current. All squirrel-cage motors are designed for "across-the-line" starting.

Maximum flexibility of control had to be obtained without impairing the reliability of operation by the use of excessive delicate automatic paraphernalia. Interlocking of operation was considered necessary to assure proper handling of the pulverized coal.

It is imperative that the induced draft fan be in service before any attempt is made to start the blowers, lest the furnace be put under pressure, forcing an explosive mixture out into the boiler room. After the induced-draft fan has been put in operation the secondary blower can be started, or if it is desirable to run at low ratings when all of the air is supplied by the exhausters, the latter are started, for it is not necessary to have the secondary blower going to start the exhausters. Furthermore, only one exhauster need be operating. The mills can now be started. As with the exhausters, only one mill need be run, but it can only be the one whose exhauster is in motion. The feeder is the last piece of apparatus that can be thrown in and, of course, only the feeder of the mill that is rolling can be started. Between the damper at the induced-draft fan inlet and the induced-draft fan is an interlock, arranged so that it is impossible to increase the speed of the fan unless the damper is in the wide-open position. The object of this is to prevent the operator from using needless power to produce the necessary suction when he might obtain that draft by opening the damper. The reverse operation is interlocked in the same way. In case of failure of any one auxiliary, those preceding drop out of service.



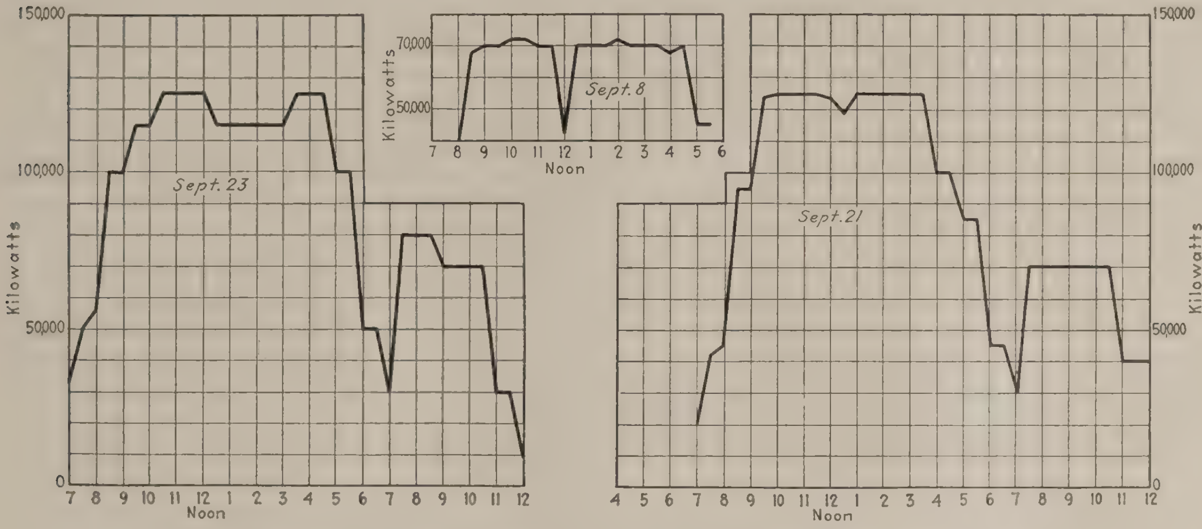
*Wiring diagram for electrical equipment controlling bank of four boilers*

There is a special condition in which the sequence mentioned is not followed. When the coal is wet and the fires are being lighted for the first time it has been found that the wet coal ignites quicker if the mixture of coal and air going to the furnace is a very rich one. The easiest way to accomplish this is to have the mill grinding before starting the exhauster, so that when the latter is started the grinding ring will contain a large amount of very fine coal and the first rush of primary air will carry a heavy charge of coal into the furnace. The normal sequence is automatically re-established immediately after starting so as to maintain full protection.

The control of all the apparatus is centered at the boiler panel. Besides carrying the push-button stations, this panel supports pressure gages, boiler meters, draft gages, $CO_2$ meter, etc., necessary for the operator's complete information. The contactor panels, resistors, controllers, temperature and low-voltage relays, watt-hour meters, etc., with the exception of the resistors and controller for the induced-draft fans, are all mounted on a mezzanine floor almost directly beneath the boiler panels. Fan controllers are motor driven. Motor-driven controllers were not used on the mills because they were so situated that a mechanical control could be very easily arranged.

The induced-draft fan, located on the economizer floor above the boiler room, is driven from either end of the shaft. On one end is a 75-hp., 375-r.p.m., squirrel-cage motor and at the other a 400-hp., wound-rotor, slip-ring motor whose synchronous speed is 750 r.p.m. The speed range is divided into fourteen intervals, the lowest speed being full-load speed on the squirrel-cage motor and the highest the full-load speed on the 400-hp. motor. In starting up it is only necessary for the operator to press the "start" button located on the boiler panel, thereby placing the smaller motor across the line. Increasing the speed is done by pressing the "fast" button, having first, of course, opened the damper to the wide-open position. This operation opens the contactors of the 75-hp. motor and puts the 400-hp. motor on the line with all the resistance in the rotor circuit. The "fast and slow" button is nothing more than a reversing switch that operates the pilot motor on the controller. This motor is equipped with a solenoid brake to avoid overtravel, while undertravel is prevented by additional copper segments, placed at the top of the drum, with connections from the "fast and slow" switch through a holding coil and the damper limit switch to the pilot motor.

The controller and control for the secondary blower motor is identical with that used on the induced-draft fan drive with the exception that it handles but one slip-ring motor rated at 100 hp. at its full load speed of 720 r.p.m. The speed range is two to one and is accomplished in thirteen steps. The exhausters are driven by 60-hp. squirrel-cage motors. A General Electric magnetic contactor operated by a push button, mounted on the turbine panel, comprises the control.



*Wide fluctuations in power demands occur at Huntley station over period of day (Sept. 8, 21 and 23, 1927)*

BOILER OPERATOR'S LOG FOR THREE DAYS

| | | |
|---|---|---|
| **Sept. 8** | | |
| | 8:00 a.m. | Lighted fire (drum pressure 100 lb.) |
| | 8:10 | On line |
| | 11:50 | Shutdown (load dropping) |
| | 12:20 p.m. | Burners relighted |
| | 12:25 | On line |
| | 4:48 | Shutdown (load dropping) |
| | 5:05 | Off line |
| **Sept. 21** | | |
| | 7:45 a.m. | Lighted fire (drum pressure 120 lb.) |
| | 7:50 | On line |
| | 9:27 | Boosted rating (cleaning stoker fires) |
| | 9:55 | Dropped rating (fires cleaned) |
| | 3:05 p.m. | Increased rating |
| | 5:07 | Dropped rating (load dropping) |
| | 5:40 | Shutdown (station dropped 45,000 kw.) |
| | 7:25 | Lighted fire (station picked up 40,000 kw.) |
| | 7:30 | On line |
| | 10:40 | Shutdown (load dropping) |
| | 11:00 | Off line |
| **Sept. 23** | | |
| | 7:25 a.m. | Lighted fire (drum pressure 195 lb.) |
| | 7:26 | On line |
| | 12:00 p.m. | Increased rating (cleaning stoker fires) |
| | 3:45 | Dropped rating (load dropping) |
| | 6:40 | Shutdown (station dropped 50,000 kw.) |
| | 7:15 | Lighted fire (station picked up 50,000 kw.) |
| | 7:20 | On line |
| | 9:40 | Shutdown (load dropping) |
| | 9:50 | Off line |

The mill motors are slip-ring induction, having a continuous rating of 125 hp. at 360 r.p.m. The speed ratio is two to one and the controller, like the others, provides thirteen steps.

The feeder motors, which are rated at 1½ hp., have a speed range from 1,800 r.p.m. (full-load speed) to 600 r.p.m., which is provided by a Ward-Leonard resistor placed in the shunt field of the motor. Thirty-three equal speed steps are thus provided.

Each feeder motor control is augmented by a signal system consisting of a light placed at the mill fed by the feeder, a gong located on the mill floor, a lockout switch situated at each feeder and necessary relays. This is done to enable the boiler operator to notify the mill man when one of the feeders is out and to designate which feeder it is. By pressing the signal button the operator causes the gong to ring and the light to appear at the troublesome feeder. The mill man upon arriving at the feeder opens the lockout switch, thereby stopping the gong (so that it may sound the alarm again if another feeder goes wrong) and extinguishing the signal light at the mill. He also puts out the indicating lamps on the panelboard which show whether the feeder is "in" or "out." When he has cleared up the trouble he closes the lockout switch and in so doing causes the "green" indicating lamp on the panelboard to light, telling the boiler operator that all is O.K. and the feeder may be restarted.

The damper control is a reversing switch connected through limit switches which prevent the motor operating after the damper has reached full-open or full-closed position. The damper-driving motor is a 1½-hp. squirrel-cage unit. This motor, like all the others, is equipped with a thermal overload relay.

The results of operation have been most gratifying. It is so simple to light a fire in the boiler and put it on the line that during some days of widely fluctuating load the boilers are often started up and shut down several times. The three charts, together with the boiler operator's log shown here, give a very good idea of how the boilers are operated. The charts are all from No. 15 boiler, tests on which were described in *Power*, issue of Nov. 22, 1927.

# Finds Exhaust Gases Impracticable for Heating

By H. C. Thuerk

*Manager Erie Lighting Company, Erie, Pa.*

ONE of the power customers of the Associated System recently investigated the possibility of installing a small power plant and generating instead of purchasing power. Careful study of both steam and Diesel-engine-driven plants showed that it would be more economical for the industrial customer who was enlarging his manufacturing facilities to continue the purchase of energy to meet additional requirements.

Among the arguments advanced for the installation of the Diesel-engine plant was the utilization of the heat units in the exhaust gases and in the jacket cooling water. It was thought that this would materially reduce the amount of fuel required for heating purposes during the winter season. An investigation showed, however, that the saving is relatively small.

In determining the amount of heat which could be recovered from the exhaust gases of the proposed oil engines the following quantities were used:

| | |
|---|---|
| Average temperature of exhaust gas, deg. F. | 600 |
| Average outside temperature, deg. F. | 50 |
| Percentage of original heat of fuel in exhaust gases | 30 |
| Temperature of steam at 5 lb. pressure, deg. F. | 228 |

It is considered good practice not to cool the gases lower than about 50 deg. F. above the saturation temperature of the steam. Lower temperature would require a much larger heat transfer surface. Assuming that the exhaust gases may be cooled to 278 deg. F. in passing through an exhaust heat boiler, then the percentage of heat available for steam generation would be

$$\frac{600-278}{600-50} \times 100 = 59 \text{ per cent}$$

Since 30 per cent of the original heat in the fuel is contained in the exhaust gases, then the proportion of the original heat of the fuel which is available for steam generation will be 30 × .59 or 18 per cent.

The following table shows the amount of steam which would be generated under both present and future load conditions of the plant by utilizing this waste heat:

| | Present Load | Future Load |
|---|---|---|
| Kilowatt-hours generated per month | 40,000 | 80,000 |
| Fuel used in gallons | 4,000 | 8,000 |
| Heat units in fuel at 18,500 B.t.u. per pound | 555,000,000 | 1,100,000,000 |
| Heat units available for steam generation | 100,000,000 | 200,000,000 |
| Pounds of steam generated at 70 per cent boiler efficiency, feed water temperature 130 deg. F. | 66,600 | 133,200 |
| Pounds of steam available for seven months | 466,200 | 932,400 |
| Tons of coal saved at 6 lb. evaporation | 39 | 78 |

It was problematical as to how much of the heat in the cooling water could be utilized. This water might be used for boiler feed water during the time the engines were in operation, but since the returns from the heating system would also be utilized for boiler feed it was apparent that cooling water could be used only to supply the losses in the heating system and additional make-up water.

It would have been possible to install a small amount of hot water radiation and return the jacket cooling water through this system. However, an auxiliary supply of hot water would be required when the engines were not running, which fact made this plan not so simple as it appeared.

If the cooling water were passed through a small hot water system the maximum saving in fuel would be computed in the following manner. If the outlet temperature of the cooling water is 130 deg. and the inside temperature of the building is 70 deg., then the heat available for heating would be

$$\frac{130-70}{130-32} \times 100 = 61 \text{ per cent}$$

Assuming that 30 per cent of the original heat in the fuel is contained in the cooling water, then the total heat which could be utilized each month is

$$555{,}000{,}000 \times 0.30 \times 30 \times 0.61 = 100{,}650{,}000 \text{ B.t.u.}$$

The coal saved during seven months would have been

$$\frac{100{,}650{,}000}{1{,}050 \times 6 \times 2{,}000} \times 7 = 56 \text{ tons}$$

This was the maximum saving possible. On account of engines not running all the time and variations in the outside temperature, it would probably not have been possible to utilize more than 60 per cent, or the equivalent of about 34 tons, during the heating season.

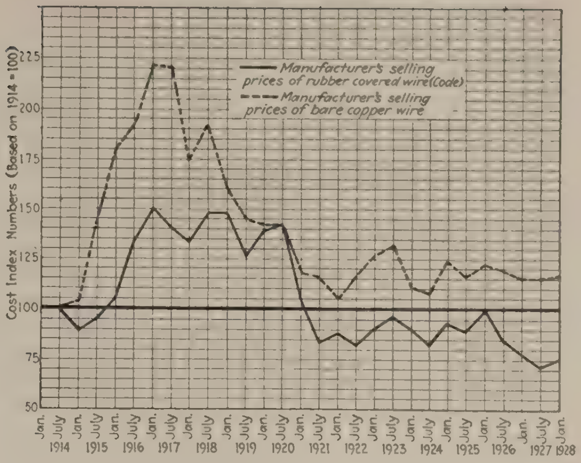
It was evident then that the maximum utilization to be expected from the waste heat in the exhaust gases and cooling water would have been equal to 73 tons of coal per year under present conditions and something less than double this amount under future conditions. Against this saving in fuel must be balanced the fixed charges and maintenance costs on the additional equipment required for utilizing the waste heat. When this was done, it was found that the net saving was so small as to make an inconsiderable difference in the total amount of coal that would have to be burned during the heating season.

# Apartment Building Floodlighted During Construction

A NEW use for floodlighting is developing in Seattle, Wash., to establish the location of a building under construction. It is worthy of wider application. The accompanying illustration shows the Marlborough apartments floodlighted with fourteen 1,000-watt units placed on nearby light poles. The building, thus brilliantly illuminated, attracted attention for some distance and was well fixed in the public mind by the time it was completed.

# Trend in Prices of Supplies

Prices virtually down to a pre-war basis. Items listed make up 60 per cent of average jobber's total sales

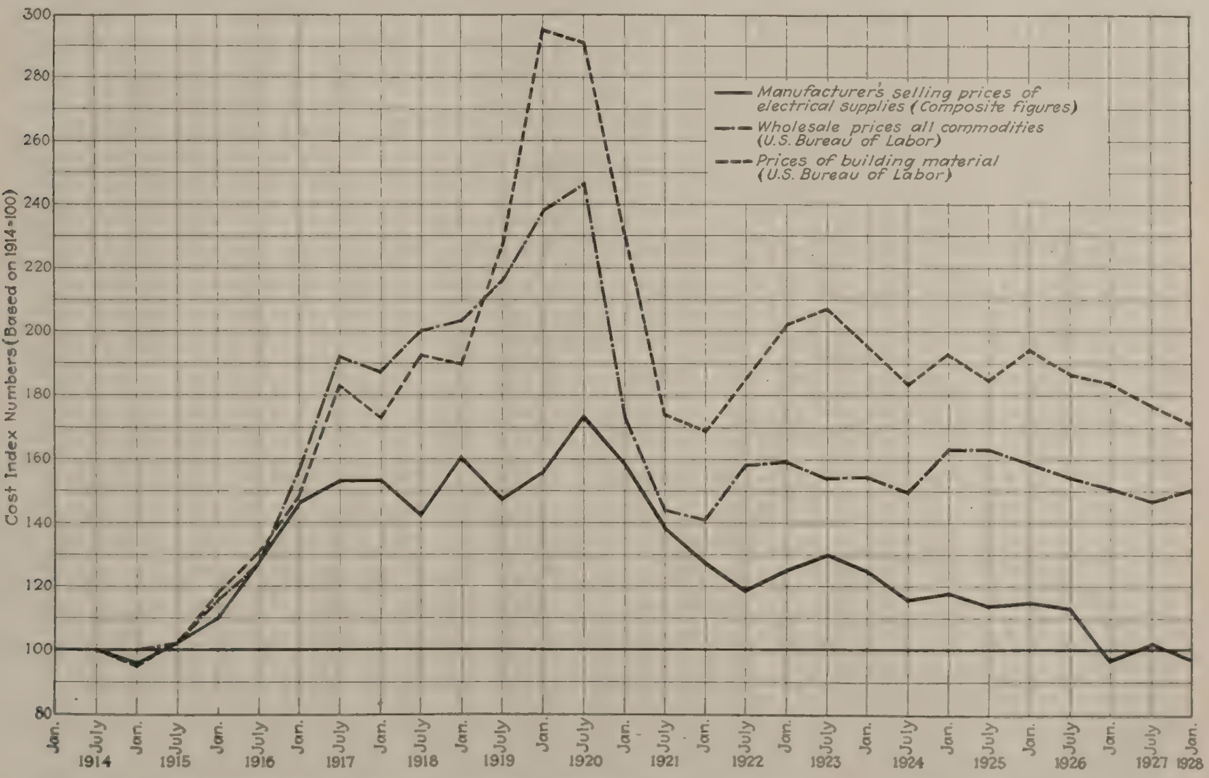


*In July, 1927, the index price of rubber-covered code wire was 71, the lowest recorded. In January, 1928, the index was 75*

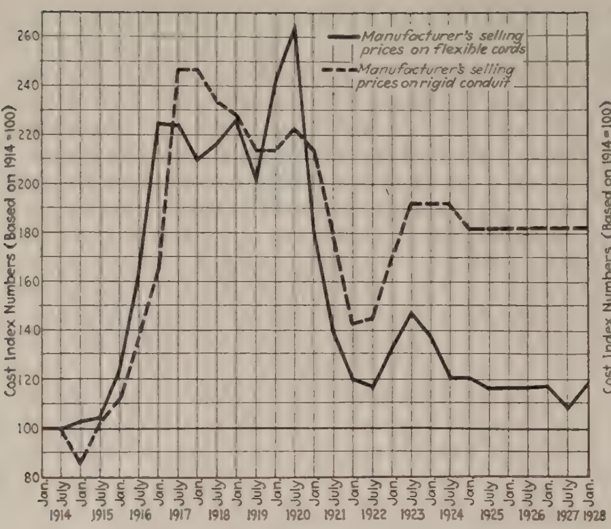
PRICE indexes of electrical materials, originally presented in the Feb. 16, 1924, issue of the ELECTRICAL WORLD, to include figures for January, 1928, are given in the accompanying table and graphs. The figures given cover manufacturers' selling prices of representative electrical commodities and were obtained from a fully authoritative source. The information is given in the form of index figures based on 1914 prices, making it possible to arrive at the manufacturers' selling price of any one of the items for any date since 1914 if the price is known for any period between 1914 and 1926. The prices are the average for the months as shown.

The index has continued to decline and the composite index number now indicates that the prices of electrical supplies are virtually down to a pre-war basis. The figures are, of course, national in character and are not influenced by local conditions which may exist or which may have existed during the period covered. The index numbers are, generally speaking, a comparison of the prices of unit quantities of a typical size, type or design of an item in each particular line representative of the whole. The index numbers, therefore, are quite accurate in showing the price movement in such items as wire, batteries, rigid conduit, tapes and compounds and standard porcelain, but there has been some difficulty in getting a true index of items that have shown marked changes in type and design during the period.

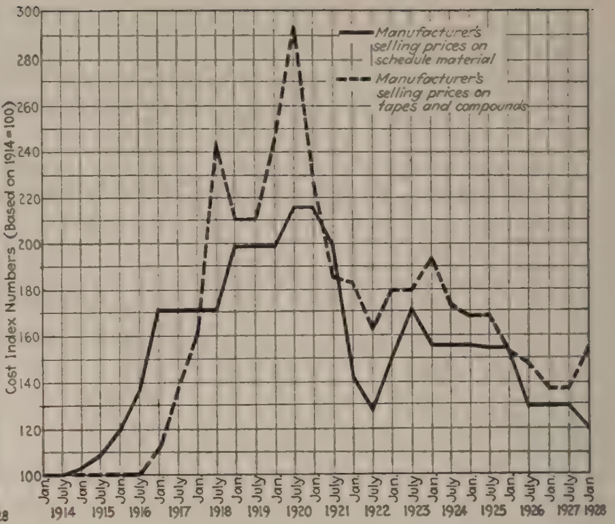
While all the items entering into the general group of commodities known as "electrical supplies" are not included in the accompanying table and diagrams the thirteen items for which data are given cover a large per-



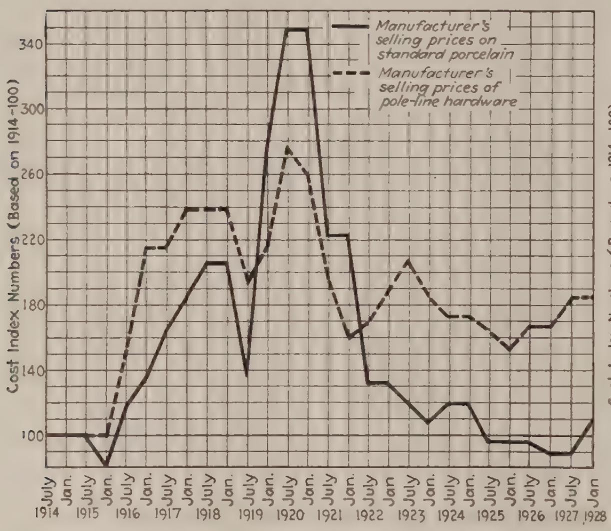
*Comparative price indexes of electrical material, all commodities and building material*



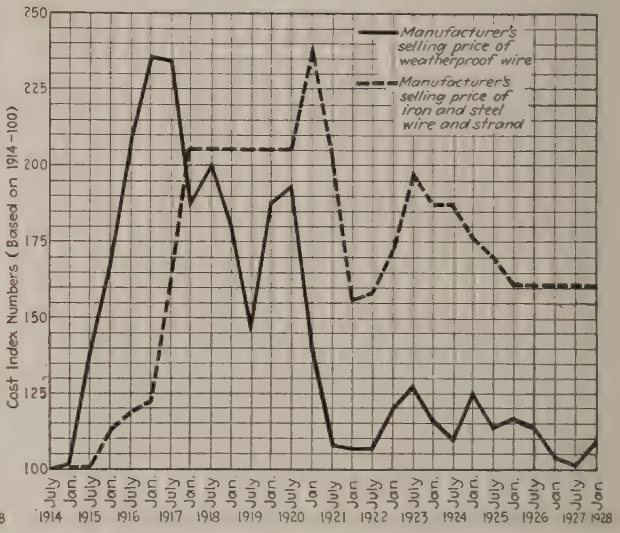
*Prices of flexible cords and rigid conduit more than doubled from 1917 to 1921. Since 1924 the index for flexible cords has been around 120 and since 1925 rigid conduit has held at 182*



*Both tapes and compounds and schedule material have registered declining prices in the last three years. In January, 1928, the index for tapes and compounds increased to 154*



*Standard porcelain prices show a steady decrease to an index of 98 in July, 1927. In January, 1928, the index was 109. Since January, 1926, pole line hardware has gradually increased to 185*



*The price of weatherproof wire in January, 1928, was only 109 per cent of that in 1914. In July, 1927, it nearly reached par. Iron and steel wire and strand has been at 161 since 1926*

*Price Index of Electrical Materials at Manufactur*

(Based on 1914 Prices = 100)

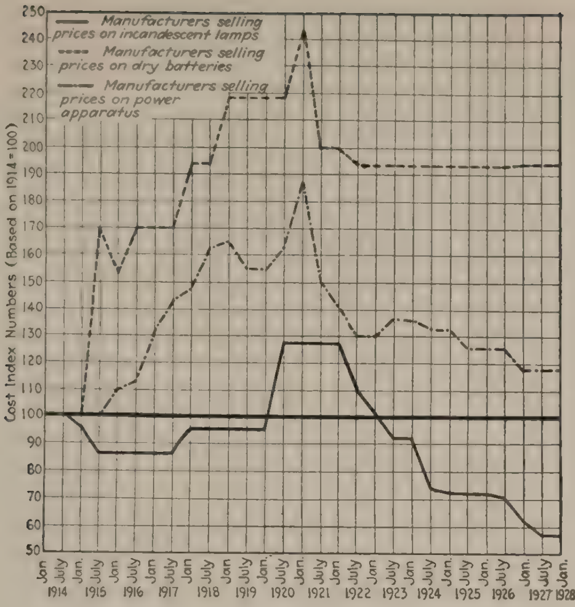
| Electrical supplies (composite figure) | 100 | 96 | 102 | 110 | 127 | 146 | 153 | 153 | 142 | 160 | 147 | 155 | 173 | 159 | 139 | 128 | 119 | 125 |



*In January, 1928, incandescent lamp prices were only 57 per cent of the 1914 price*

centage of the electrical supplies manufactured. A somewhat higher composite index number would be obtained if more items were included, but it is estimated that the items listed comprise about 60 per cent of the average jobber's total sales. The figure given is a physical volume index and the individual indexes are weighted by the volume of sales for each item. Incandescent lamps weight the index heavily in the winter months and this item, together with rubber-covered and weatherproof wire, operated strongly to bring the index down to the pre-war level. The price of wire varies considerably in the various classes. Weatherproof wire follows very closely the prices of bare copper wire.

The extent to which the prices of electrical supplies as a whole have been held down by manufacturers since 1914, as compared with the wholesale prices of commodities and the high prices asked for building materials, is clearly shown in an accompanying illustration. During the peak year 1920 the increase in the price of electrical supplies was considerably less than that of all commodities or building material. In January, 1928, the composite figure for electrical supplies was 97, compared with 150 for all commodities and 171 for building material

# Ten Months' Sale of Electrical Farm Equipment

THAT the central-station company has a strong influence and responsibility in developing the use of electrical equipment by farm customers is shown in the results which have been attained by the Ohio Public Service Company, Elyria, Ohio, through its work in conjunction with a local farm implement dealer. As outlined on page 817 of the ELECTRICAL WORLD, April 16, 1927, the Ohio Public Service Company arranged an extensive permanent display of electrical farm equipment in the store of the Farm Implement Company in Elyria. This was followed by a series of demonstrations and the rural lines representatives of the power company invited existing and prospective farm customers to visit the display and inspect the equipment in operation. Many sales to rural customers have resulted and in the first full year's operation of this display more than $30,000 of electrical equipment has been sold. An itemized list of the apparatus sold during the first ten months is given here.

FARM EQUIPMENT SOLD IN TEN MONTHS OF DISPLAY UNDER SPONSORSHIP OF OHIO PUBLIC SERVICE COMPANY

| No. | Equipment | Value | No. | Equipment | Value |
|---|---|---|---|---|---|
| 78 | Electric water systems | $8,461.00 | 22 | Corn poppers | $54.00 |
| 10 | Electric milking machines | 432.00 | 26 | Curling irons | 45.00 |
| 2 | Cream separators | 304.00 | 2 | Heaters | 35.00 |
| 6 | Electric brooders | 90.00 | 8 | Fans | 40.00 |
| 66 | Electric washing machines | 10,080.00 | 25 | Hotplates | 75.00 |
| 2 | Ventilating fans | 70.00 | 18 | Coffee percolators | 147.00 |
| 17 | Vacuum cleaners | 551.00 | 2 | Large feed grinders | 250.00 |
| 60 | Flatirons | 325.00 | 2 | Chicken feed grinders | 45.00 |
| 55 | Toasters | 185.00 | 4 | Large irrigation systems | 8,200.00 |
| 20 | Waffle irons | 130.50 | 1 | Electric 1½-hp. motor | 129.00 |
| | | | 1 | Electric drill and saw set | 35.00 |
| | | | 20 | Christmas tree light sets | 40.00 |

Commenting on these results, J. B. Johnson, district manager of the Ohio Public Service Company, said: "This is a formidable list, but it is a very small percentage of even a fair saturation and represents only a small part of the business that can be developed. It represents the results from only one effort in one county in Ohio, but it tends to indicate what can be accomplished when a workable contact is established by the central-station company with rural customers and the farm implement dealer."

# "D.R." Plan Sells Many Appliances

THROUGH the courtesy of Stone & Webster, Inc., manager of the Electric Light & Power Company of Abington & Rockland, Mass., the results of the district representative plan of customer contact pioneered on that property are now available for 1927. Each district representative serves about 800 residential customers in an assigned territory, reading meters, attending to service matters, adjusting complaints, selling appliances and in general giving the company a living personality in his neighborhood. During 1927 the nine district representatives of the company sold $99,777 worth of electrical appliances, or an average of about $11,000 per man. The company serves a large rural territory interspersed with small towns, and its total sales of appliances in its own store were $6,628 for the year. Lamps are included in the foregoing figures. The maximum and minimum appliance sales per "D.R." were $20,453 and $6,464 respectively. These appliances add an annual energy consumption of about 391,550 kw.-hr. to the company's business. The average appliance purchases per residence customer for the year, including lamps, was $18.42. The gross profits on the appliances sold more than covered the labor of the district representatives, including meter reading and servicing. About 40 per cent of the time of these men was expended on merchandise sales during the year. In 1926 the total sales were $99,169.

### *Norway Claims 2,400 Kw.-Hr. per Capita*

*To the Editor of the* Electrical World:

I have seen with interest the statistics of the electrical industry given in the Jan. 7, 1928, issue of the Electrical World and shall be glad if you will help me correct an error in the statistics.

In one of the graphic tables on page 34 it is stated by your statistician that the generated electrical energy in Norway in 1925 was only about 220 kw.-hr. per capita. We are proud that we are living in one of the best, if not the best, electrified countries in the world, and in 1925 our energy consumption was about 6,700,000,000 kw.-hr., or 2,400 kw.-hr. per capita. Twenty-five per cent of the energy was used for public utility purposes. With these figures we beat even the state of Montana, which, according to the table on page 60, had 2,020 kw.-hr. per capita (in 1927?) and is the leading state of the U. S. A.

In this connection it would be interesting to know whether the total production of energy in Montana is consumed in that state or whether a certain part of the energy is exported to other states. Trygve Hodne.

[The figures on which the chart in the Jan. 7 issue was based were subsequently published in the Electrical World, Feb. 11, 1928, together with the source of the information. The output was there given as 6,200,000,000 kw.-hr., or 2,270 kw.-hr. per capita, which figure should be used instead of that shown on the chart. The slight discrepancy between this 2,270 and 2,400 kw.-hr. quoted by Mr. Hodne (mailed Feb. 14) is apparently due to differences in information coming presumably from official sources.—Editor.]

### *Improvements in Turbo-Generators and Speculations Upon Them*

*To the Editor of the* Electrical World:

The editorial appearing on page 441 of the March 5 issue of Electrical World entitled "Improvements in Turbo-Generators and Speculations Upon Them" is very interesting and brings out one point in particular that I have been interested in for some years, although I have never had an opportunity of doing anything in this line, namely, the use of a refrigerant in connection with such units. In view of the very wide application of mechanical refrigeration to industry, which includes its use in many specialized manufacturing operations, it would seem that there should be no insurmountable difficulties in adapting refrigeration to turbo-generator design. The cooling and conditioning of air by means of mechanical refrigeration has been a reality for years, as has been the case in the cooling of other gases.

In turbo-alternators, where hydrogen gas is used as the cooling agent, such gas could be cooled through any desired range and its temperature automatically controlled within very close limits. All that the refrigerating engineer would need to know to calculate the necessary refrigerating tonnage for a given installation would be the weight of hydrogen gas circulated per unit of time and its specific heat, the range through which the gas is to be cooled and the heat equivalent of the horsepower required to circulate the gas. It is obvious, of course, that a scheme of this character could not be adopted overnight, but would require careful study and investigation, and no doubt a certain amount of experimental work would be necessary. However, any practical and economical means of maintaining the generator windings at the lower temperature levels is well worth serious consideration.

By the use of mechanical refrigeration, any practical heat head or temperature difference could be maintained between the highest temperatures of the generator and the cooling medium, with the result that large quantities of heat could be taken up.

The amount of power actually required to operate a refrigerating machine of sufficient capacity to produce the necessary cooling would be a very small percentage of the total auxiliary power required by turbo-generators and would unquestionably be an excellent return on the investment. C. T. Baker.

Atlanta, Ga.

### *Let the Seller Profit*

*To the Editor of the* Electrical World:

In commenting upon the articles you have been publishing on the subject of price cutting, there is no question in my mind that it is good policy to follow the lead of the leading automobile concern that recently was reported to have given instructions to its buying department that it must cease "hard buying" and pay a price fair to the manufacturer as well as to itself. In a recent article in the New York *Times* I made the following statement, which is to the point:

> There are, however, many other angles to the buying of merchandise that need to be considered in this general question. It is obvious that if buying were to be confined to paying the "first price" offered there would be no need of a purchasing agent.
>
> The purchasing agent is an officer of the corporation, and as such he views a purchase from general market conditions rather than as a single transaction. He has to watch the market to be sure he is not overpaying and that concerns which compete with his own are not able to buy more cheaply. He naturally is trying to get a little better quality at a price which is a little lower. And his success in this endeavor plays a large part in the success of the entire corporation.
>
> The buyer frequently has no reliable or entirely accurate information as to what the bottom price is on certain merchandise in which he is interested. Accordingly, in dealing with certain types of salesmen, the job of the purchasing agent is to smoke out the "confidential stuff." In every purchase, as I have said, he is guided by the relation of the price he is asked to pay to that paid or likely to be paid by his competitor.
>
> If a manufacturer finds himself with a big inventory and is forced to make concessions to get orders, no buyer is going to pay more than the prevailing market conditions warrant. This manufacturer speculated in covering his raw material requirements in advance, and if he did not gage the action of the market correctly that is his error.
>
> These considerations deal solely with market conditions and do not parallel the seeking of the "last drop of blood," of which sellers can rightly complain.

There is every indication of a greater degree of co-operation and mutual understanding between buyers and sellers. In no way can this be fostered better than by the realization that a fair profit for both is essential.

W. L. Chandler,
Secretary and Treasurer.
National Association of Purchasing Agents.

## *Hydro-Electric Development and Steam Equipment*

*Heating Trash Rack Bars Electrically.*—C. R. Reid.—In order to combat anchor or frazil ice, formed in turbulent open water in the forebay of a hydro station subject to extremely low temperatures, electrically heated trash rack bars were devised. The author reviews the installation and offers the empirical formulas utilized in developing this equipment. Performance details are included. It is stated that the best method of overcoming this ice trouble lies in the proper design of the hydraulic system above the rack bars, as a large body of quiet water will freeze over quickly and an ice covering of sufficient size will be formed to prevent the surface formation of heavy ice crystals. The ice needles either adhere to the under side of the ice covering or are remelted in the warmer water under the ice. If the velocity approach is low and the racks are set at a considerable depth, and if, in addition, the bed of the approach channel is smooth and grades down easily to the bottom of the racks or even considerably below that, frazil ice trouble should be entirely eliminated. However, when this is not possible other precautions must be taken. In the present installation a voltage of 126.5 and a current of 3,680 amp. are utilized, giving an input per cubic feet per second of 227 watts. It is stated that sufficient experience has been gained with this installation to demonstrate that just about the right amount of energy input has been provided. Severe frazil ice conditions have been handled with entire success at this plant on several occasions. The author concludes that electric heating of racks is of particular value in locations where frazil ice trouble develops quickly and is not of long duration. When such trouble is experienced more or less continuously it is suggested as being desirable to install rack bars made of tubing welded into headers and to circulate warm water through them as temperatures and conditions may require.—*Electrical News (Canada)*, March 15, 1928.

## *Heat Applications and Material Handling*

*Electric Heating and Load-Factor Improvement.*—M. O. F., England.—As a result of an analysis and investigation of available mediums for the improvement of load-factor conditions the author has concluded that the desired results can be obtained by creating a load consisting of electrically heated water storage cylinders and controlling this load from the power house or substation by inexpensive means. It is said that under certain conditions the cost of supplying hot water in this way compares very favorably with coke fuel, especially with the smaller consumer. The larger consumer may pay a little more for his hot water, but the initial expense is small, and in other ways the electric system is ideal. The electrical equipment suggested for such installation consists of a simple form of remote relay control, while the operating voltage is so low that no danger is incurred, even if bare wires are run overhead on ordinary telephone poles and insulators. This discussion, of course, refers to possibilities following the practices involved in Great Britain. The containers must be properly insulated to prevent the diffusion of the stored heat.—*World Power (England)*, March, 1928.

## *Transmission, Substations and Distribution*

*Insulating Oils for High-Voltage Cables.*—T. N. Riley and T. R. Scott.—Oils suitable for high-voltage cables are in general equally suitable for low-voltage work, according to the authors, but many of the characteristics which are of importance for high voltages are of minor importance when the stress in the dielectric is low and the range of oils available is therefore increased. Chemically, there are said to be few fundamental requirements, since it is the physical and electrical properties which determine the most suitable compound. Physically, the compound must have the properties of a lubricant in order that the paper layers may slide over each other without fracture when the cable is handled. The viscosity must be sufficiently low at the processing temperature to permit thorough impregnation of the paper. On the other hand, it must be sufficiently high at service temperatures to prevent easy drainage when the cable is laid on a slope or when it is cut for splicing. The author reviews the necessary fundamental characteristics and presents determinations arrived at through exhaustive laboratory tests. It is concluded that the physical requirements severally mentioned are essential if a well-impregnated cable is to be constructed. It is shown that the power-factor-temperature characteristic of the oil is of importance, not only in relation to the actual value of dielectric losses exhibited by the cable, but also as an index of the state of chemical and physical stability of the oil. The elimination of gas pockets in the dielectric is of vital importance, not only for preventing burning and oil oxidization, but for obtaining low thermal resistivity.—*Electrician (England)*, March 9, 1928.

*220-Kv. Lightning Arresters.*—A. L. Atherton.—The use of lightning arresters on the terminal stations of the Conowingo-Plymouth Meeting line is of interest as it constitutes a departure from the previous general conception that lightning arresters are not needed for such service, or at least that they are not economically justified at 220 kv. and also because the arresters are said to be the largest in service. The study which preceded the decision to utilize this equipment has been outlined in this discussion to determine the benefits to be secured by such protection. Consideration was given to the insulation of the proposed line station yard and apparatus. Assumptions were made as to the most severe transient likely to occur on the line. The proper arrester was selected to suit the anticipated operating voltage of the station. From the characteristics of the arrester and line and from the station layout determinations were made of the voltage which will be applied to the station equipment when such a maximum transient arrives at the station. It was found that these voltages may be potentially dangerous, but that special choke coils will reduce and may be expected to eliminate this danger. As a result of this investigation, it is indicated that there are probably many other cases in which such a study would point out hazards both of yard flashover and apparatus damage which might be avoided by some relatively minor changes in the protection scheme. —*Electric Journal*, March, 1928.

## *Units, Measurements and Instruments*

*The Neon-Electric Stroboscope.*—E. E. Steinert.—The need for a stroboscope that could be used in the study of power system stability to measure, among other things, the various displacement angles caused by different load conditions has been met by the development of the neon-electric stroboscope. This device consists of four parts: A special transformer, a condenser, a neon lamp and a disk. The transformer, condenser and neon lamp are inclosed in a case for protecting the lamp against breakage and the operator against high voltage. The only electrical connections to the case are those leading to the transformer primary, which operates from a 110-volt, 60-cycle supply and the only technique required in its operation is to place the box where the light can fall upon the disk. No tuning or adjustments are necessary. As the investigators use the disk directly not through slots or past vibrating parts an element of considerable simplicity is introduced. The element which makes this stroboscope effective is the special transformer, the secondary voltage of which is characterized by a sharp, well-defined peak. The author states that the success with which the neon-electric stroboscope has been used in recent tests is a direct result of its high degree of accuracy, which is possible only because of the extreme clearness of the image. Other features of this device are compact and rugged construction. It is said to be as portable as an ordinary voltmeter.—*General Electric Review*, March, 1928.

*Symmetrical Components.* — C. F. Wagner and R. D. Evans.—A brief review of the laws governing complex numbers precedes the development of certain theorems regarding the resolution of simple complex numbers into symmetrical groups. These developments apply largely to electrical systems involving symmetrical or balanced impedances. Illustrative examples of these theorems are offered in connection with specific examples, such as the analysis of short circuits in transmission networks. This is followed by the application to a few miscellaneous problems, some of which involve unsymmetrical impedances. The treatment is limited to three-phase systems, except that the last portion of the discussion develops some of the more important relations as applied to two- or four-phase systems. It is stated that a knowledge of the method of symmetrical components is essential for an adequate understanding of the application problems involving the magnitude and phase relation of voltages and currents under unbalanced conditions and is therefore necessary for the design of power stations from the standpoint of cricuit-breaker application, relay protection and stresses in electrical machinery. The method is particularly suitable for the analysis of the performance of rotating machinery for single-phase or unbalanced polyphase operation and has been used quite extensively in connection with the design of machinery on single-phase railway systems, particularly from the standpoint of phase-converting apparatus.—*Electric Journal,* March, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*Thickness of Photo-Electrically Active Rubidium Films.* — Herbert E. Ives and A. L. Johnsrud.—The extreme tenuity of the layer responsible for photo-electric emission offers a possible answer to what has been a long-standing question with regard to selective and normal photo-electric emission. The question is stated by the authors to be, why does the emission under certain circumstances differ for a light polarized in and perpendicular to the plane of incidence, by a factor many times greater than the ratio of the optically measured absorptions? In the light of the experiments described in this article, it appears possible that the intrinsic absorption of the extreme surface layer may differ, for light polarized in the two planes, by a very large factor, but that the total optical absorption, which is due to a relatively considerable depth of material, may not exhibit this difference. A definite orientation of surface atoms, overlying atoms randomly disposed, could result in behavior of this sort. In any event, whatever the cause of the high selective-to-normal-emission ratio, it is clear, for the subject matter considered, that any close correlation of bulk optical properties with photo-electric properties is not necessarily to be expected.—*Reprint B-282, Bell Telephone Laboratories, Inc.*

*The Deterioration of Lead Cable Sheathing by Cracking and Its Prevention.* — S. Beckinsale and H. Waterhouse.—The phenomenon of the cracking of lead cable sheathing received little attention by metallurgists until recently, according to the author, and has only been studied as a corollary to other forms of intercrystalline cracking, and, in particular, season-cracking. The results of the numerous and extensive researches into the causes and methods of prevention of season-cracking of brass and other metals appear, however, to be inapplicable to the case of cracking of lead. Because of the almost negligible elastic limit of the metal and its readiness to self-anneal at atmospheric temperature it is stated that a state of internal stress of sufficient magnitude to cause intercrystalline failure of the season-cracking type is improbable. The investigation covers microscopic and chemical determinations for suspended aërial cable, underground construction and other installations where such failures were found.—*Engineering* (*England*), March 9, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*Economical Design of Loaded Telegraph Cables.*—E. S. Heurtley.—The economical design of a cable of any given length and required transmitting speed is considered and it is shown that in general for equal performance a cable intermittently loaded is materially cheaper to manufacture than a cable loaded throughout. A brief outline of the methods employed in obtaining the results is given. The author includes a number of suggestions for reducing mechanical costs and suggests the possibility of duplex operation as a method of further minimizing expenses.—*Electrician* (*England*), March 9, 1928.

*Experiments and Observations Concerning the Ionized Regions of the Atmosphere.*—R. A. Heising.—Experiments are described by the author in which a virtual height of the reflecting ionized region was measured, using time lag between impulses arriving over a direct and reflected path. Movements of the reflecting region are plotted, showing slow rises and rapid drops. Transmission measurement curves are given, showing dependence of meter signals upon night ionization and the assistance that sunlight ionization can give. Experiments and curves are mentioned that show absorption to be one of the important factors causing poor daylight transmission in the wave length region contiguous to 214 m. It is pointed out that the absorbing region is below the refracting region and that the sky wave must make two passages through the absorbing region. According to this theory the electromagnetic waves from the sun produce the ionization in the absorbing region and part of the day ionization in the refracting region. This ionization is pictured as beginning at an altitude of about 16 miles and extending upward, and as experiencing diurnal and seasonal variations.—*Reprint B-283, Bell Telephone Laboratories, Inc.*

## *Traction*

*The Operating Costs of Electric Industrial Trucks and Motors.*—C. B. Crockett and H. J. Payne.—The authors have endeavored to show how direct and indirect costs of a materials-handling system may be classified and estimated and have applied the methods described to the question of operation of electric trucks. The direct costs of operation are here divided into fixed charges and operating charges, both of which are fully enumerated and where possible evaluated. Actual figures of cost of operation taken from several plants are presented and the savings due to truck operation pointed out. The various items entering into cost estimates have been defined in relation to the life of the trucks, battery, charging equipment, etc. As a result of this investigation the authors conclude that the effort to lower the cost of production in the mechanical handling of materials is becoming increasingly significant, but that variations in conditions render comparative cost estimates somewhat difficult; that a fairly simple classification of direct cost is possible; that in average installations the electric cost is in the neighborhood of 50 cents an operating hour; that in specific installations there is considerable variation in cost; that the influence of operating conditions is capable of being analyzed, and that indirect savings are always present, though difficult of valuation.—*Electric Vehicle,* March, 1928.

## *Miscellaneous*

*The Vacuum Slip Process of Removing Air from Clay Bodies.*—G. W. Lapp.—The author has described the fundamental considerations involved in the slip-process manufacture of plastic wet process electrical porcelain bodies. The method of manufacture has been outlined as the passage of the clay through a tank in which the air content is evacuated by boiling. The ability of the clay filter cakes to reabsorb a small amount of air insures freedom from air in the clay if the milling devices are properly designed and operated. The advantages of such a manufacturing process are outlined and the method of determining the air contents is also given. The latter involves the compression of the sample in a liquid-filled chamber. It is stated that determinations may be made by this method with an accuracy of one-hundredth of 1 per cent. This test procedure was devised by Professor Bridgeman and is stated to have been highly successful. —*Journal of the American Ceramic Society,* February, 1928.

# News of the Industry

## Massachusetts Rate Bill Postponed a Year

*State Senate Accepts Committee's Recommendation to Put Utilities Commission's Plan Over Until Next Session—Attwill Protests*

THE proposed bill of the Massachusetts Department of Public Utilities forcing electric and gas companies to accept commission regulation without appeal to the courts in case of unacceptable decisions on rates has been referred to the next session of the Legislature by the report of the Senate committee on power and light. The Senate accepted this report on Wednesday. The committee tried to draft a permissive bill but encountered so many obstacles that no agreement was possible. The constitutionality of the bill was sharply questioned in the committee discussions.

Commenting on the report of the committee, Chairman Attwill of the Massachusetts Department of Public Utilities said that the board will continue its fight to establish the principle that the public shall not be required to pay rates based on surplus earnings taken from the public through excessive charges or based on fictitious and fanciful valuations. He declared that unless in the near future the commission shall succeed in this effort, there will be no relief from extortionate charges except through public ownership.

## Protests Against Plant in the Royal Gorge Number 150

A crowded audience assembled at Pueblo, Colo., on March 29, when the application of the Public Service Company of Colorado to build a hydro-electric plant in the Royal Gorge, near Canon City, came before the Public Utilities Commission of the state at an open hearing. This application has aroused unusual interest on account of the allegation that the plant would destroy or injure the scenic beauty of the gorge, well known to travelers through that territory. One hundred and fifty formal protests against it have been registered. The project had been referred back to the state by the Federal Power Commission on account of the strong opposition, that commission saying: "The question whether or not this project should proceed in view of possible conflict with other interests seems peculiarly a matter of state concern, over the decision of which the state, having the authority, should assume the responsibility."

V. L. Board, general superintendent of the company, said that it would not go ahead in the face of opposition, but would be willing to agree to a stipulation for the exemption of sufficient water to maintain the scenic feature of the gorge. He dwelt on the cost of natural gas and coal as fuels. E. Clinton Jansen, company engineer, said that the plant could be operated without any loss to the natural beauty of its surroundings. Barton M. Jones, an engineer representing the Denver & Rio Grande Western Railroad, which is fighting the hydro project vigorously, held that the Public Service company could find other sites, naming one on the St. Vrain River.

## Santa Cruz Defeats Municipal Water and Power Scheme

The proposed municipal water and hydro-electric power project designed to make the city of Santa Cruz, Calif., tax-free in ten years was defeated by the voters on March 29. The vote stood: For, 1,774; against, 2,390. The vote was the heaviest ever recorded for the thirteen precincts of Santa Cruz. It had been proposed to erect a dam above the city to supply Santa Cruz with municipally owned water service and to sell power to local industries.

## Three Committeemen Attack Shoals Bill

### Minority Report to House Says It Involves "Enormous Waste of Public Money"—King for New Study of Boulder Dam—Utility Quiz Next Week

By Paul Wooton
Washington Correspondent of Electrical World

A VIGOROUS minority report on Muscle Shoals was submitted to the House of Representatives April 4. It was signed by Representatives Ransley of Pennsylvania, Frothingham of Massachusetts and Glynn of Connecticut. The minority report says that the corporation to be set up by the government would be "merely a start toward the goal of unlimited expenditure of government money." It attacks the provisions of the bill for fertilizer production as based on "the most expensive method." The report continues:

> No provision is made for paying back past expenditures at Muscle Shoals, which amount to over $123,500,000. The Patent Office is opened to this government corporation and the patent law, though still binding on private manufacturers, is swept aside for this corporation. The bill also authorizes the expenditure of some $37,500,000 for a new dam, and not only is no provision made for amortizing this sum, but vested rights that the State of Tennessee may possess are ignored.
>
> There were other and better bills before the committee than this one—bills which would have involved less expenditure of the people's money and been quite as effective. The War Department receives an annual rental for the water power at Muscle Shoals of $1,250,000, and the expenses are only $276,000. This is a trifle compared with the yearly revenue that could be obtained if the department were empowered to make a longer lease, but it shows that money is coming into the Treasury, that the taxpayer will be protected while waiting for a business proposition, and that there is no need of haste in accepting a bill until the right one comes before us. We object to the enormous waste of the public money involved in the present bill and to the operation in this manner by the government of what should be left to private enterprise. There is grave doubt also as to the constitutionality of this bill.

A hand in the pending Muscle Shoals legislation is being taken by the National Fertilizer Association. This body is about to issue a statement of which an advance copy has reached the Electrical World. The statement, which was to go to every senator and representative by Friday, declares that if the Norris bill shall become a law, the government will be in the fertilizer business in the fullest sense and a cardinal American principle thus be overthrown. The association asserts that of all important supplies bought by the American farmer the lowest-priced is fertilizer; that the fertilizer industry, so far from profiteering, has lost $225,000,000 since 1920 through overproduction, and that the Norris plan would utterly fail to set up a substitute and would in itself be an economic crime.

### Asks New Study of Boulder Dam

With a definite place assigned to the Boulder Dam bill on the Senate's legislative program, there is increased interest in the effort being made to require a further engineering study before final action is taken. A bill introduced by Senator King of Utah to bring about such an investigation contains the following provisions:

> The President is hereby authorized and empowered to make an investigation to determine the most economical, available and effective means for the utilization of the water resources of the Colorado River basin, including the Colorado River proper and all of its confluences and tributaries, and for this purpose the President is authorized to appoint, by and with the

advice and consent of the Senate, a commission to consist of three persons, two of whom shall be engineers of recognized standing who are not interested in any project for the use of any such water resources and another person who has a practical knowledge of hydraulics and the financing of enterprises for the use of water for irrigation and for the generation of power.

Senator King's bill goes on to particularize what the proposed investigation shall cover, including stream flow, present use of waters, silt deposit, irrigation, flood control, reservoir sites, cost of dams and other works, potential generation of power, physical relations of upper and lower basins as regards water supply, the projected all-American canal and the existing situation affecting Mexico. The bill asks for "general and comprehensive conclusions upon all factors involved," together with cost estimates.

### Utility Hearing Next Week

The Federal Trade Commission announces that its next public hearing in connection with its investigation of public utilities will be begun in Washington on Wednesday, April 11, when documents pertaining to publicity methods obtained from three large utility associations and one state utility information office will be introduced. Recent charges to the effect that the Copley Press, Inc., of Illinois and California, is controlled by utility interests will be gone into. Documents to be introduced will be from the files of the New York and Washington offices of the Joint Committee of National Utilities Associations, the geographic divisional office of the National Electric Light Association at Springfield, Ill.; the Chicago office of the Illinois Committee on Public Utilities Information, and offices of the American Gas Association, in all of which places investigators for the commission have been at work. Records in several other divisional offices of the N.E.L.A. are being examined by specially detailed men. Representatives of the various associations will be subpœnaed.

The Federal Power Commission has disapproved legislation proposed by Senator McKellar and Representative Garrett, both of Tennessee, which would remove the non-navigable tributaries of navigable streams from its jurisdiction.

# Southwestern Men Report Excellent Year

## Good Spirit and Optimism Pervade Meeting on the Gulf Coast—National and Division Officers Tell of Progress—Onken Views Present-Day Tendencies

THE Southwestern Geographic Division of the National Electric Light Association, which embraces electric public utility companies operating in the States of Oklahoma, Texas, Arkansas, Louisiana and Mississippi, held its eighth annual convention at Edgewater Gulf Hotel, Biloxi, Miss., on April 2 to 5. The attendance and spirit which pervaded the convention were excellent, owing primarily to the interest which executives have shown this year and to the excellent committee reports.

Numerous men from outside the division addressed the meetings. Prominent among the latter were President H. T. Sands and Managing Director Paul S. Clapp of the national association; W. H. Onken, Jr., editor of the ELECTRICAL WORLD; E. C. Stone of Pittsburgh, chairman of the Engineering National Section; T. O. Kennedy of Cleveland, vice-chairman of the Commercial National Section; Dean C. O. Ruggles of Ohio State University; J. F. Owens, chairman of the Public Relations National Section, and Earle W. Hodges of H. L. Doherty & Company.

Mr. Sands and Mr. Clapp told of the aims and accomplishments of the National Electric Light Association, explaining in some detail the work of the various committees and the functioning of the thirteen geographic divisions. The work of the Southwestern Division was described by E. E. Armstrong of Gulfport, Miss., president of the division. He attributed its excellent record during the past year to the men and women on the firing line and to the support which their activities merited and received from the executives of the majority of the companies in the five states.

Mr. Onken showed the great extent to which the Southwest has been benefited by the operations of the electric light and power companies and how these, relying chiefly on natural gas, oil and powdered lignite for fuel, are not greatly concerned over water power and coal. He made a plea for the coordination of agriculture and machine-operated industry in the interest of a balanced economy to insure the economic independence of the United States and presented a broad view of the farm problem and the part electricity can play in it. He touched upon the legislative situation and the present era of consolidations and mergers. The processes of consolidation, he said, must go on to the very ultimate of their economic application, and in the process there must be a scrapping of obsolete and inefficient equipment because operating margins are becoming so small that neither thrill nor benefit can be derived out of a wasted dollar.

Of the many good committee reports the most noteworthy was that of the Engineering Section. Its hundred pages were filled with practical suggestions and descriptions of electrical and other engineering applications peculiar to the Southwest. Another noteworthy move was reported by the power division of the Commercial Section. It has initiated and partly developed an excellent power reference manual to facilitate the work of the electric light and power companies in obtaining power business.

Officers for the ensuing year were elected as follows: President, J. G. Holtzclaw, Gulf States Utilities Company, Beaumont, Tex.; vice-presidents: C. R. Bertron, Jr., Houston Lighting & Power Company, Houston, Tex.; F. W. Insull, Public Service Company of Oklahoma, Tulsa; H. C. Couch, Arkansas Power & Light Company, Pine Bluff; M. T. Walker, Southwestern Gas & Electric Company, Shreveport, La.; B. E. Eaton, Mississippi Power Company, Gulfport. S. J. Ballinger, San Antonio (Tex.) Public Service Company, was re-elected as secretary.

## Federal Radio Commission Members Confirmed

Confirmation by the United States Senate of four presidential nominees to the Federal Radio Commission was finally obtained on March 30. These were O. H. Caldwell of New York, Sam Pickard of Kansas, Harold A. Lafount of Utah and Ira E. Robinson of West Virginia. Mr. Robinson was recently appointed to fill the place of the late Admiral Bullard. The other three were *ad interim* members, Mr. Caldwell having served since the commission was formed a year ago. Senator Dill again led the opposition to Mr. Caldwell's confirmation, accusing him of favoritism to the Radio Corporation of America and other interests, but the commissioner won by a vote of 36 to 35.

The commission now has its full membership of five. It has still to elect a chairman. Judge E. O. Sykes of South Carolina, the only previously confirmed member, has been acting in that capacity.

## Public Service's Substation at Union City, N. J.

The first distribution substation of so-called 1927 design was connected to the lines of the Public Service Electric & Gas Company on March 18. It is known as the Union City substation. It was designed and constructed by the Public Service Production Company and embodies several novel features. The transformer banks are separated by brick fire walls, which are not ordinarily employed in other than major installations. The arrangement of the switchboard, on the second floor of the substation, follows the standard recently adopted for transformer and low-tension-feeder panels but inaugurates a new departure in other respects. The transformers and the 4,150-volt circuits are controlled from panels arranged in front of the individual circuit-breaker positions in such a way as materially to shorten the length of conduit runs and as to provide a space between each panel for ready access to the circuit-breaker solenoids and to the wall-mounted line-drop compensators. The remaining panels in the substation are installed back to back, parallel to the low-tension-feeder panels, the rear panels being used for relays and the front panels, which are hinged, for high-tension-line control switches and indicating instruments.

The substation is situated on the side of a hill and therefore required special consideration in the layout of the outdoor equipment, it being necessary to obtain a terraced effect. Connection is to a double 26,400-volt loop, two three-phase circuits connecting the station to the Seventh Street substation, West New York, and two to the Hudson switching station, which latter is in turn connected to the Electric & Gas company's 132-kv. transmission system. The station supplies at 4,150 volts part of North Bergen Township and nearly all of Union City.

## Buffalo General Electric Company Overcomes Mishaps

How two threatened interruptions to service in Buffalo in one week found the Buffalo General Electric Company prepared for emergency and were overcome without inconvenience to the public, few citizens knowing anything about them, is thus related by a company official, at the request of the ELECTRICAL WORLD:

Work is now under way on the rewinding of armature coils in one of the 37,500-hp. generators at the Schoellkopf station of the Niagara Falls Power Company, at Niagara Falls, N. Y. One of these coils burned out early in the evening of Wednesday, March 28. It had been observed during an inspection of the armature some time ago that the coils were nearing the end of their useful life. Complete materials for the repairs were ordered at that time and were on hand at the time of the failure. The machine was promptly dismantled, the old winding was removed and is now in the process of reconstruction. It is expected that the job will be completed in about four weeks. Insulation caught fire when the failure occurred. The operator immediately turned on the water in the sprinkler system, and the fire was completely extinguished with only slight damage. There was no disturbance on the system, as differential relays cleared the generator automatically. The company took advantage of the burn-out to replace the windings with coils of improved design.

Interconnection of power sources enabled Buffalo to avoid a serious interruption on Friday, March 30. An unusually severe windstorm, accompanied by sleet, caused trouble on the transmission lines from Niagara Falls, but through interconnected lines it was possible to maintain service until the disturbance was over. Wind direction and velocity were just right to cause whipping of the lines from the William B. Rankine station, in Niagara Falls, Ontario, and the Schoellkopf station, in Niagara Falls, New York. This "jumping" of conductors occurred only on lines running north and south, lines running east and west not being affected. The Charles R. Huntley station quickly swung into action, and with a shift in the direction of the wind the trouble soon cleared.

## Ontario Hydro Reports No New Generators in 1927

*Five and a Half Millions Has Been Spent on Rural Service—Total Power Output 1,073,630 Hp., Almost Identical with That for 1926.*

THE annual report of the Ontario Hydro-Electric Power Commission, which was tabled in the provincial legislature on March 30, shows that the total capital expenditure in rural power districts is $5,569,179. Of this amount, $5,232,551 covers units in operation and $336,628 covers those in course of construction. No additional generators were placed in operation during the year, and consequently the growth in the load has reduced the margin between available generating capacity and the demand for power. The past year was the first since 1918 when no increase in generating capacity was made. The total increase in peak load was 71,500 hp., as against an increase of 56,000 hp. the previous year. All systems showed an increase in the average load. Taken on the whole, the peak loads showed an increase of about 11 per cent, which is close to the average growth established during the past ten years. The kilowatt-hours, however, did not increase in proportion.

The total power purchased and generated in the year was 1,073,630 hp., while the 1926 total was 1,072,387 hp. Operating conditions in the Niagara system, the report states, changed very little in the year. The load-dispatcher system inaugurated in 1926 was continued and developed to give the greatest possible power output for the amount of water which the commission is allowed to divert from the Niagara River. An increase of 66,000 hp. in this load, or about 11 per cent, is reported.

Dealing with the Georgian Bay system, the report states that there was an increase in the load over 1926 resulting from the increases in industrial loads and the operation of new industries. The load on the St. Lawrence system increased very rapidly during the year, and this was covered by arrangements with the Cedars Rapids Transmission Company to increase the power contract to the extent of 1,200 additional horsepower. The demands for power on the Central Ontario and Trent system show a substantial increase. Both peak and average loads in the Nipissing system showed heavy increases over the previous fiscal year.

## Gadsden on Issue Raised by Muscle Shoals Bills

Legislative invasion by the federal government of the field of private enterprise as embodied in the Muscle Shoals resolutions recently reported at Washington was discussed at Newark, N. J., on Wednesday evening by Philip H. Gadsden, vice-president of the United Gas Improvement Company and vice-chairman of the Joint Committee of National Utility Associations. Mr. Gadsden spoke before a gas conference. He said:

"Reduced to essentials the question is: Shall the federal government confine its activities to the political field, leaving its citizens free by their initiative and enterprise and self-reliance to develop the field of business? Has the time come when we can safely turn over to the government the management and control of the electric power industry, one of the chief factors in our amazing industrial development?"

## Oil Breakers Withstand a Million Volts

ON THE right are shown three 220,000-volt oil circuit breakers built by the General Electric Company for the Philadelphia Electric Company and recently subjected to a test at 1,000,000 volts. A spectacular view of a discharge at that voltage is shown on the left. The arc measured 18 ft.

## Regional Spring Programs for Institute

*Baltimore Gathering Will Discuss Dielectrics and Power Generation—New Haven Meeting Will Take Up Unusual Technical Developments in Connecticut*

DETAILS of the two spring regional meetings of the American Institute of Electrical Engineers—that of the Middle Eastern District at the Hotel Belvedere, Baltimore, April 17-20, and that of the Northeastern District at New Haven on May 9-12—have been made public. At Baltimore dielectrics and power generation will come in for special attention, and papers describing the Gould Street station of the Consolidated Gas, Electric Light & Power Company and the Conowingo plant of the Philadelphia Electric Company by engineers with these respective companies will be included. Inspection trips to the two plants just named will be made—the first on Wednesday afternoon, the second on Friday morning. On the evening of Tuesday Dr. R. W. Wood, professor of experimental physics at Johns Hopkins University, will lecture on "Sounds That Burn." Many entertainment features will be provided. The chief items in the technical sessions follow:

### TUESDAY, APRIL 17

*Afternoon.*—"Behavior of Dielectrics," R. R. Benedict, University of Wisconsin; "Thermal Method of Standardizing Dielectric-Power-Loss Measuring Equipment," J. A. Scott and H. W. Bowsman, General Electric Company, and R. R. Benedict, University of Wisconsin; "Developments in the Insulation of Coils for High-Voltage Turbo-Generators," C. H. Hill, Westinghouse Electric & Manufacturing Company; "Drying and Evacuating of Impregnated Paper Insulation," J. B. Whitehead, W. B. Kouwenhoven and F. Hamburger, Jr., Johns Hopkins University.

### WEDNESDAY, APRIL 18

*Morning.*—"Gould Street Generating Station of Consolidated Gas, Electric Light & Power Company," A. S. Loizeaux; "Design Studies for Gould Street Generating Station," F. T. Leilich, C. F. Follmer and R. C. Dannettel; "Operating Experiences at Gould Street Generating Station," A. L. Penniman and F. W. Quarles.

### THURSDAY, APRIL 19

*Morning.*—"Conowingo Hydro-Electric Development on the Susquehanna River," Alexander Wilson, 3rd; "Electrical Features of the Conowingo Generating Station and the Receiving Substations at Philadelphia," R. A. Hentz; "220-Kv. Transmission Lines for the Conowingo Development," P. H. Chase.

*Afternoon.*—"Telephone System in Connection with the Conowingo Development," W. B. Beals, Chesapeake & Potomac Telephone Company, and E. B. Tuttle, Bell Telephone Company of Pennsylvania; "Quantitative Mechanical Analysis of Power-System Transient Disturbance," R. C. Bergvall and P. H. Robinson, Westinghouse Electric & Manufacturing Company; "Superexcitation for the Synchronous Condensers for the Conowingo System," D. M. Jones, General Electric Company.

### NEW HAVEN PROGAM

One of the sessions of the New Haven meeting will be devoted to a joint symposium arranged by the committee on instruments and measurements and on protective devices. Three other sessions will be based on four unusual technical developments in the vicinity of New Haven which will be about completed by the time that the meeting is held. These are in the field of hydro-electric development, railroad and street-railway power and mercury turbines.

The Connecticut Light & Power Company is completing a development by which the excess flow of the Housatonic River will be pumped into a storage basin through utilization (a) on some occasions of a portion of the excess water power and (b) on other occasions of steam power from other points on the system. This will be the feature of an all-day inspection trip on Saturday, May 12, and will also be covered by a paper by E. J. Amberg of the Connecticut Light & Power Company. Similar papers dealing with corresponding development of other rivers in New England and the South are in preparation.

The fact that power for the trolley system of Bridgeport is being supplied exclusively by mercury-arc rectifier substations, one of which is entirely automatic, will be the subject of two papers, one by G. E. Wood of the Connecticut Company, on the principles and details of the installation, and a second by C. J. Daly of the Southern New England Telephone Company, on the handling of inductive co-ordination. To inspect the New York, New Haven & Hartford Railroad electrification—now being supplied with 25-cycle power through two variable-ratio frequency-changer sets, one of which derives power from another 25-cycle system, the second from a utility system at 60 cycles—will be the object of another inspection trip, and papers by Ludwig Encke of the railroad and E. J. Burnham of the General Electric Company will be read. C. F. Schuchart, Commonwealth Edison Company, and W. K. Vandersluis, Illinois Central Railroad, will present a paper on a similar phase of the Illinois Central electrification.

The 10,000-kva. mercury-boiler turbine being installed at the South Meadows station of the Hartford Electric Light Company will be operating before the date of the sessions, and there will be a paper describing that installation and discussion by the company officers. An inspection trip to this installation will also be made.

Besides these events, there will be another session including miscellaneous topics made up chiefly of "initial" papers by members of the district. The Friday morning session will be turned over to the branches of the Northeastern District for a student program, along the lines of that at Pittsfield in 1927. The three evenings will be devoted to a reception and dance, a banquet and a theater party, respectively. Those attending the convention are to see a complimentary performance by the Yale University department of drama at the University Theater.

For the summer convention of the Institute, to be held at Denver June 25-29, electrified railroad equipment, surge investigations, carrier current, geophysics, operation at high altitudes and engineering education will be among the topics.

## Electrification of Railroads Makes Progress in East

As already reported from time to time, several Eastern railroads are busy with electrification programs. The Pennsylvania Railroad has almost completed the overhead installation from Wilmington, Del., to Philadelphia. A trolley voltage of 11,000 will be used at first on this section of the railroad, and power will be purchased from the Philadelphia Electric Company for both this section and that from Philadelphia to West Chester.

It is now reported on good authority that the Pennsylvania has authorized further electrifications which will be made in successive steps. These include the main line from Philadelphia to Newark and the line from Philadelphia to Pittsburgh. Newark will replace Manhattan Transfer as the station where a change to the downtown New York tubes can be made. Power will be purchased by the Pennsylvania from adjacent utilities, and a large generating station is being designed by the Public Service Company of New Jersey to afford the required energy in its territory as well as to care for system load growth.

Delaware & Lackawanna commuters have offered to pay increased fares to New York if this railroad will carry out its electrification plans, and it is asserted, though not confirmed, that the project will be started soon.

The plans of the Philadelphia & Reading Railroad to electrify its line from Philadelphia to Langhorne, Pa., a distance of 24 miles, have previously been reported.

The New York Central & Hudson River Railroad has made an analysis of the economies and service advantages of electrification from New York to Albany and thence to Buffalo, and a favorable decision is expected in the near future.

The extended utility systems make possible an adequate power supply in these regions, and the use of high-voltage trolleys combined with purchased energy reduces the railroad investments very materially. In the next few months a very large electrification program for these Eastern railroads is likely to be adopted.

---

## Engineering College for Los Angeles' University

Next September will see the inauguration of a college of engineering at Los Angeles, established as part of its educational equipment by the University of Southern California. This university began courses in engineering 23 years ago, and the increasing demand for technical education has now led it to set up the new college, which will provide adequately equipped laboratories and facilities. There will be five major divisions, devoted respectively to chemical, civil, electrical, mechanical and petroleum engineering. Prof. Philip S. Biegler will be the first dean as well as the head of the electrical engineering division. Four-year courses will lead to the degree of bachelor of science in any of the divisions, and masters' degrees will be awarded for graduate work.

## Southeastern Division Miami Program Adopted

Headquarters for the Miami Beach (Fla.) convention of the Southeastern Geographic Division, N.E.L.A., to be held on April 11 to 14, will be at the Roney Plaza Hotel. Main features of the program follow:

WEDNESDAY, APRIL 11

*Morning.*—President's address, Joe H. Gill; address, H. T. Sands; merchandising talk, Harrison Jones; address, John M. Hager, United States Department of Commerce.

*Afternoon.*—Committee reports.

THURSDAY, APRIL 12

*Morning.*—"Functions of the Public Relations Section," John F. Owens; "Southeastern Public Relations Section and Its Work," Jackson P. Dick; "Accomplishments of the Southeastern Engineering Section," R. W. Lamar; "How Can the Southeastern Commercial Section Be of Service?" A. B. Collins; "Accomplishments of Southeastern Accounting Section," H. W. Boozer.

*Afternoon.*—Engineering, Commercial and Accounting Section meetings.

FRIDAY, APRIL 13

*Morning.*—"Developments in the Electrical Industry," Paul S. Clapp; address, Miss Eloise Davison; "Developing Domestic and Commercial Load," Phillips B. Shaw; address, Dr. Gus W. Dyer, dean School of Economics, Vanderbilt University; "Electricity on the J. C. Penney Small Farms" and "Rural Electrification Development in the Southeast," by representatives of the Florida Power & Light Company.

## Experts Say Inadequate Foundations Caused Dam Failure

Findings of a commission of six experts appointed by Governor Young of California to investigate the cause of failure of the St. Francis Dam in southern California on March 13 are embodied in three conclusions in a report filed with the Governor. These conclusions are: (1) Failure of the dam was due to defective foundations. (2) There is nothing in the failure to indicate that the accepted theory of the gravity-type dam is in error. (3) Failure of the structure indicates the desirability of having all such structures erected and maintained under supervision and control of state authority.

The engineers report that samples of foundation taken from underneath the westerly wall quickly softened and changed to either a mush or a granular mass when immersed in water. "Unfortunately, this material," the report finds, "is of such nature that when entirely dry it is hard and rocklike in appearance and characteristics, although defective in compressive strength. With such a foundation the ultimate failure of this dam was inevitable, unless water could have been kept from reaching the foundation.

"Photographic evidence and the testimony of witnesses showed that little seepage passed through the structure of the main dam. Certain cracks developed in the main structure which possibly discharged an unimportant amount of water, not at all unusual in concrete dams. Much more important seepage is reported to have taken place through the foundation upon which the dam rested. As the water rose in the reservoir, this foundation seepage appears to have increased to a maximum of between one and two second-feet on the afternoon preceding the failure. Rumors of muddy water seeping under or around the dam before its failure are in circulation, but the commission has been unable to verify them."

A similar finding was made on Wednesday of this week by a board of engineers and geologists appointed by the Los Angeles District Attorney. This board declared that the dam should never have been built on the site selected.

## Purchases and Mergers

*Southeastern Power & Light Acquires Edisto Company in South Carolina—Absorption of Small Municipal Plants Into Company Systems Goes On*

SALE of the Edisto Public Service Company, which, with headquarters at Denmark, S. C., serves 23 rural communities in Barnwell, Bamberg, Allendale and Hampton Counties in that state with light, power, water and ice, to the Southeastern Power & Light Company is announced. The Edisto company was formerly controlled by the Atlantic Public Utilities.

The California Railroad Commission has approved the purchase by the Great Western Power Company of California of the Feather River Power Company (ELECTRICAL WORLD, March 31, page 676).

Directors of the New Bedford (Mass.) Gas & Edison Light Company are considering an offer for the utility company from the Eastern Utilities Association.

The Public Utilities Corporation has acquired the electric lines owned and operated by Dr. E. M. Nichols at Barton, Vt., which, as reported last week, the town of Barton voted to acquire and operate. Discovery that the town could not take over the utility without legislative enactment, which could not be had until January, 1929, caused the town to turn its option over to the Public Utilities Corporation, a subsidiary of the W. B. Foshay Company.

Stone & Webster have announced that a majority of the common stocks of the Blackstone Valley Gas & Electric Company, the Edison Electric Illuminating Company of Brockton, Mass., and the Electric Light & Power Company of Abington & Rockland have been deposited in exchange for shares in the Eastern Utilities Association (ELECTRICAL WORLD, March 10, page 525). The plan of merger has therefore been declared operative.

The Connecticut Power Company has announced that a recently acquired minority interest in the Union Light & Power Company, Unionville, Conn., implies no intention of obtaining control. The Union company is an independent utility.

The Southern Light & Power Company of Maryland has purchased the Millington (Md.) Electric Light & Power Company's lines and plant from C. S. Church, who recently developed the property.

Efforts to acquire the municipal electric light and power plant in Centreville, Md., together with the pole lines and equipment owned by the towns of Queenstown and Church Hill, have been renewed by J. H. Drake, vice-president of the Eastern Shore Public Service Company, who offers in writing "to pay a price in excess of $160,000 if the Public Service Commission should determine, after a thorough investigation, that the value of your property is in excess of the price we are offering."

Authority to purchase the Home Light & Power Company, serving five small communities in Henry County, Ind., from Frank Crull for $35,000 is sought by the Interstate Public Service Company.

An offer from the Inland Utilities Company of Kansas City of $155,000 for the light plant at New Albany, Miss., was rejected by a vote of 447 to 28 last week.

Further delay in getting before the Indiana Public Service Commission the plan arranging the consolidation of the Terre Haute, Indianapolis & Eastern Traction Company properties with the power-distributing properties of the Central Indiana Power Company has been occasioned by an alteration in the conditions for the exchange of securities, and many months may yet elapse before the deal is consummated.

A proposal for sale of the municipal electric plant at Monroe, S. D., to the Northern States Power Company of Sioux Falls will be submitted at a special election April 17.

The Kentucky-Tennessee Light & Power Company has bought the city light and power plant at Trezevant, Tenn., for $16,600.

Citizens of Erick, Okla., on March 27, by vote of 228 to 90, approved sale of the municipal electric light and power plant to the Southwestern Light & Power Company. Several months ago Erick voted a franchise to the company, but a proposal to sell the plant at that time failed to get the necessary 60 per cent of the vote.

The annual report of the Telluride Power Company of Utah says that control of the Big Springs Power Company and the Pahvant Power Company was taken last year.

The Canadian Hydro-Electric Corporation, which controls the hydro developments of the International Paper Company in Canada, has announced the taking over of three hydro-electric plants on the Ottawa River. Two of these, owned by the Ottawa & Hull Power Company, are at the Chaudière Falls, Hull, Quebec, and the third station, owned by the Ottawa River Power Company, is at Bryson.

## Bill to Condemn Seattle Utility Property Not Hailed

A bill has been introduced in the Seattle City Council by Councilman W. T. Campbell which provides for the city's condemning or otherwise acquiring the properties of the Puget Sound Power & Light Company. The bill has some support, in a general way, among the councilmen, but on the whole is considered untimely for any practicable purpose. The proposed measure provides an initial appropriation of $25,000 for an appraisement of the company's holdings, including its distributing system within the city and the power plants on White River, Baker River and at Snoqualmie Falls. Oliver T. Erickson, chairman of the City Council utilities committee and long a leader among municipal ownership supporters, attacks the plan as "absurd and destructive."

# Briefer News

Seven Ohio Municipal Plants Sold in 1927.—Seven municipal light plants in Ohio were sold to privately operated companies during 1927, according to a report of the Ohio Committee on Public Utility Information—Johnstown, Piketon, Waverly, Peebles, Olmsted Falls, Jefferson and Milbury. Twenty-one in all were sold in the past five years.

Colorado Electrical Men Get Together.—The third annual state-wide meeting of Colorado electrical men, under the sponsorship of the Electrical League of the state, held on March 26 at the Cosmopolitan Hotel, Denver, was addressed by B. J. Rowan, J. J. Cooper, Clyde L. Chamblin, G. B. Buck and others. C. N. Shannon led a round-table discussion on the relationship of the various groups.

United Public Service Company to Establish Headquarters at Greenville, Ohio.—The United Public Service Company has purchased the Buckeye Overall building at Central Avenue and Pearl Street, Greenville, Ohio, and will make its headquarters there, according to announcement by A. O. McDonald, general manager of the Indiana-Ohio division, which embraces eight public service companies.

Yazoo City, Miss., to Sell Power.—A ten-year contract has been drawn up between the municipal authorities of Yazoo City, Miss., and the Mississippi Utilities Company of that place by which the city will sell power to the company, which in turn expects to furnish the towns of Louise, Midnight and Silver City, thus reversing the usual procedure where public and private plants cooperate.

New Mexico Power Company Has New Plant.—The New Mexico Power Company has completed its 3,800-kw. generating plant at Dawson, built at a cost of $400,000. It replaces a plant operated by the Phelps Dodge Corporation for its coal mines and is connected with the Trinidad (Colo.) plant, controlled by the Federal Light & Traction Company, New York. The plant will burn low-grade coal in pulverized form.

Kettle Falls Plant, on the Columbia, Would Afford 260,000 Hp.—Development plans looking toward an ultimate hydro-electric generating capacity of 260,000 hp. at Kettle Falls, on the Columbia River north of Spokane, Wash., were revealed at a hearing in Spokane before Major John S. Butler, representing the Federal Power Commission. Three or four years would be required for the initial development, testimony showed, owing to the unusually large flow. The complete scheme would require eight generators. Ten stages of development are now planned with the operative head increasing gradually from 35 ft. to 75 ft. There was no opposition testimony offered in behalf of town or county officials, Columbia Basin irrigation project proponents or other power companies.

Dayton Power & Light Increasing Its Plant.—More than $600,000 will be expended for additional electric generating capacity at the Miller's Ford power house during the present year, according to O. H. Hutchings, vice-president and general manager of the Dayton Power & Light Company. Growing demands in Piqua and vicinity will require the expenditure of an additional $200,000 for the construction of a transmission line from the power plant in Dayton to Covington and Piqua.

## Coming Meetings

[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]

Southeastern Division, N. E. L. A.—Miami, Fla., April 11-14. C. M. Kilian, 207 Bona Allen Bldg., Atlanta.

American Institute of Electrical Engineers — Baltimore regional meeting, April 17-19; New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities—Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Arizona Utilities Association—Prescott, Ariz., April 26-28.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A.—Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

Otter Tail Power Company's 1928 Budget.—More than $350,000 will be spent by the Otter Tail Power Company this year in improvements and expansion. Nearly two-thirds of this will be spent at Jamestown, N. D., in installing new equipment in the power station and rebuilding a turbo-generator; new waterwheels will be installed at Fergus Falls, Minn., and low-voltage lines will be built to serve ten North Dakota communities at an expense of $118,000.

Twin States Manchester-Arlington Line in Operation.—The Twin States Gas & Electric Company is distributing power from its station at Bennington, Vt., to Manchester Center, Manchester Depot, Danby and Dorset, N. H., through the recently completed 44,000-volt transmission line between Manchester, N. H., and Arlington, Vt. The first link of this line, between Bennington and Arlington, was completed in 1924.

Duke Power Company Starts Work on New Steam Plant.—The Duke Power Company has begun construction work on the first unit of its steam plant at Riverbend, on the Catawba River, 12 miles from Charlotte. The generating equipment to be used in the first unit will include two 56,000-kw. turbo-generators served by four boilers under which coal will be burned. A possible eventual installation of 450,000 kw. in this plant is announced.

Manitoba Power Company to Sell Seven Sisters Falls Energy to Provincial Government.—The Manitoba Power Company has closed a contract with the provincial government to supply 30,000 hp. annually from the company's site at Seven Sisters Falls. The contract will operate over a period of 30 years, at the end of which time the government can take over the private plant as a public utility. The power will be sold to the government at a rate of $13.80 per horsepower. A new terminal substation, costing in the neighborhood of $750,000, will be erected in Winnipeg by the Winnipeg Electric Company to take care of the production from the Seven Sisters Falls development. It will receive and distribute the additional load and effect a connection with the provincial hydro transmission system.

New Transmission Lines for Southwest Alabama.—Projects of the Alabama Power Company in the extension of its electric power system in southwest Alabama will cost approximately half a million dollars. A transmission line from Linden to Jackson, with substations at Jackson and Thomasville and the reconditioning of existing power plants in those places, will represent most of this. A 20-mile transmission line from Atmore to Bay

Minette, with a substation at the latter, is scheduled for early completion. A substation at the new state docks in Mobile is three-quarters completed.

**Luzerne County Gas & Electric Reduces Rates.**—A reduction in rates for electricity which, the company estimates, will result in a saving of about $100,000 a year to customers of the Luzerne County Gas & Electric Corporation, Kingston, Pa., is announced by A. J. Llewellyn, vice-president. The first 80 hours' use of meter capacity will still be charged for at 10 cents a kilowatt-hour, but following steps are reduced to 7 cents and 4 cents. A minimum monthly charge of $1 will be made.

**Plan Hydro Plant to Serve Cape Breton, N. S.**—Development of a large hydro-power plant at Lake Ainslie, Nova Scotia, which would cost about $1,500,000 and supply most of the power needs of Cape Breton, was urged before the provincial government recently by a delegation of citizens and county officers after conferring with engineers and the Nova Scotia Power Commission. Those interested in the project will now take up the matter with the various counties in Cape Breton, with a view to assuring a market for the power in sight.

**Holyoke Water Power Company to Build Dam on the Connecticut.**—The Holyoke Water Power Company has obtained from the United States authorities a permit to build a large hydro-electric power plant in connection with its masonry dam across the Connecticut. The plan submitted looks to four hydro-electric units having a total capacity of 40,000 hp. This installation would provide for utilization of floodwaters that now go unused during nine months of the year and would not affect the delivery of water through the hydraulic canal system. Authority is granted to make a tailrace in the rocky bed of the river and also to build a masonry wall to separate this channel from the portion of the river bed through which floodwaters naturally flow. A permit to build such a plant was granted by the Massachusetts State Department of Public Works more than a year ago.

**Further Stage Reached in British Electrification Scheme.**—A further important stage in the electrification of the suburban lines of the Southern Railway of England was reached by the completion late in March of the first stage of the Central Section scheme. The complete project is to cost $18,750,000, bringing the total expenditure to $57,500,000. The section just completed comprises the lines from London Bridge to Purley, with the Caterham and Tattenham Corner branches, and from London Bridge to Crystal Palace. Included in this section are 86 miles of track equipped with the third-rail. The second section, to be opened next June, consists of 79 miles of track, about one-half of which will be converted from the overhead wire to the third-rail system. The lines embraced are those between London Bridge and Victoria and between London Bridge and Epsom Downs. The final stage of this scheme, between Victoria and Epsom and London Bridge and Dorking North, and between the City and Wimbledon, will be opened next year.

**Cheyenne Company Builds Lighting System for Air Mail Route.**—The Pueblo-Cheyenne air mail route, approximately 200 miles long, with stops at Colorado Springs and Denver, is one of the most recent and best-lighted airways in the United States. There are 21 beacons along the way, spaced approximately 10 miles apart. Seven are operated by electricity obtained from nearby power lines, five by acetylene gas and the remainder by power units installed in the shelter house at the base of the beacon towers, like the one shown in the illustration. Six intermediate landing fields, spaced about 30 miles apart, are lighted in accordance with the latest system. Three beacons of especial interest are those on top of Castle Rock, Spruce Mountain and the water tank of the town of Nunn, on the Colorado-Wyoming border. Construction of this airway was under the direction of F. S. Peterson of the Cheyenne Light, Fuel & Power Company, which did the work.

**No Cessation of Activity in West Texas.**—Demand for electric power in the oil fields of west Texas has caused the Texas Electric Service Company to adopt plans for enlargement of its power plant at Odessa at a cost of $500,000. A 60,000-volt power transmission line extends from Odessa to the Winkler County oil fields, but immediate construction of a second line has been ordered. This will necessitate the installation of additional Diesel engines and generators in the plant and an enlargement of the main building. Last year the company was obliged three times to increase the capacity of its Odessa plant.——An extension of the power transmission line of the Texas Utilities Company from Slaton to Lamesa, approximately 60 miles, will be constructed. It will be of wooden-pole construction and will cost approximately $100,000.——Construction of a 15,000-hp. hydro-electric plant in connection with its irrigation project is proposed by the Maverick County Water Improvement District in the Eagle Pass district.——Further east an extension of the 60,000-volt transmission line of the Texas Power & Light Company from Cameron to Taylor, via Minerva, Rockdale and Thorndale, will be made. The distance is about 35 miles. The line will be of wooden-pole construction.

**Insull Companies' Rate Reductions in New England Bring Saving of $200,000.**—The Central Maine Power Company has again reduced its rate schedule, bringing a saving to customers in its eastern division of more than 10 per cent. Last month the company reduced rates in the northern section of the state. Other reductions will follow, the company says. The Public Service Company of New Hampshire has reduced rates in the past year on almost all its divisions. Reductions by the Insull companies in Maine and in New Hampshire will save customers upward of $200,000 a year.

**New England Power Offices to Be Moved to Boston.**—The entire executive offices, including the accounting and engineering departments of the New England Power Association, will be moved from Worcester to the new Batterymarch Building in Boston before Nov. 1 next. Since the organization of the New England Power Company about twenty years ago the headquarters of the management has been at Worcester, although the offices of the president and the banking interests most closely identified with the company have been at Boston. The recent acquisition by the association of the leading electric light and power utilities at Providence, Lowell and Lawrence led to the decision to centralize the managerial and allied offices at Boston, according to a statement to a representative of the Electrical World by Samuel C. Moore, vice-president and general manager. The operating headquarters of the company will continue at Worcester, with load dispatching offices at Millbury, Mass., as heretofore.

**Storage Sites for Power on Eel River, Calif.**—The geology of the Mill Creek and Elk Creek dam sites and the Round Valley reservoir site on the Middle Fork of Eel River, Mendocino County, Calif., is set forth in a report prepared by the Geological Survey. An engineering examination of Eel River made in 1922 by the Survey disclosed that its value for power was largely dependent upon the feasibility of storing the floodwaters in or near Round Valley. The most promising sites for dams were found short distances below the months of Mill Creek and Elk Creek. The present geologic report, by H. T. Stearns, shows that at the Elk Creek site the north abutment of the dam would be founded in the foot of an ancient earth slide involving an area of about a square mile. The dam could not safely be raised high enough to obtain valuable storage. The rock at the Mill Creek site, however, appears to be sound and water-tight. Round Valley has no apparent leakage. The storage capacity of Round Valley which could be developed by a dam at the Mill Creek site is greater than the annual supply of water at that place. A manuscript copy of the report may be examined at the office of the Geological Survey in Washington, D. C., or at the district office at San Francisco.

## Commission Rulings

**Allocating Cost of Service Extensions to Old and New Consumers.**—The Public Service Commission of Pennsylvania has approved an agreement whereby the Pennsylvania Power Company, instead of charging new patrons to be attached to a line originally constructed at the cost of the consumers on it a lump sum to be used to reimburse those consumers for their expense, returned to the latter 80 per cent of the money advanced by them, and all consumers on the line, including those now desiring service, agreed to pay the minimum monthly charges.

**Building of Rural Network in Territory Assigned to Another Forbidden.**—Permission to construct and operate an electrical distributing system in Sparta, Livingston County, New York, as part of a proposed network of transmission lines to serve rural communities east of Rochester, has been denied John J. O'Connell, doing business as the O'Connell Electric Company, by the New York State Public Service Commission. The commission based its action on the fact that the New York Central Electric Corporation is already equipped to serve the community. Mr. O'Connell had obtained a franchise from the Sparta Town Board under which he proposed to build a distributing line from the Niagara Power Company's line in Groveland through Sparta Township to Scottsburg. Residents and streets of Scottsburg were to be served by the transmission line. The New York Central Electric Corporation, already authorized to operate in Sparta, opposed O'Connell's petition. The company later extended its line from Sparta to Scottsburg. The commission found that business was not sufficient to warrant operation of the two companies.

**Alternating-Current Service and Competition.**—Where there is a substantial demand for alternating current, as in garages, hospitals, barber shops, stores using refrigeration, cannery industries, sawmills, woodworking plants, etc., it is mandatory on an electric utility to provide energy of this character notwithstanding the original establishment of a direct-current service by the operator. This is the spirit and intent of an order entered by the Oregon Public Service Commission in connection with the determination of operating rights in Gold Beach, Ore., and involving the interests of the J. C. Leith Electric Company and the Gold Beach Electric Corporation. The issue was whether an application for a certificate of convenience and necessity for furnishing alternating current in the Gold Beach field by the Leith utility should be granted or whether exclusive privileges should be extended to the Gold Beach Electric Corporation on condition that the latter make provisions in its published tariff for the installation of rotary converters to provide alternating current wherever direct current cannot reasonably be used. The commission held that the Gold Beach company, having filed a satisfactory tariff for alternating-current service, is now adequately serving the field and is therefore entitled to all the business in the territory.

**Refusal to Permit Recapitalization on Basis of Reproduction Cost New.**—In denying authority to the California Water Service Company to issue securities to cover the purchase of a number of water distribution systems in California on the basis of present reproduction cost new, the Railroad Commission has affirmed its long-established rule that security issues for refinancing purposes will be allowed only upon the basis of the original cost of the physical properties of public utilities less accrued depreciation but including present-day values for lands. The commission said: "If we were to base refinancing capitalization upon an estimated 'reproduction cost new,' as is urged by applicant, a situation would be created in which even slight variations in the prices of public utility materials and supplies might quickly wipe out a part, or even the whole, of the equities possessed by common-stock holders. This commission has never heretofore allowed the capitalization of potential values, nor has it permitted public utilities after a period of operation to refinance or recapitalize their properties upon such a basis that the outstanding securities thereof would be increased to reflect an alleged 'going-concern value' claimed to have been established subsequent to the construction of the properties in question. If, in the present instance, this purchaser desires to pay, or does in fact pay, more than the amount realized from the sale of the securities herein authorized for the properties or stock of the several companies here in question, the difference between said amount and such price as the vendee may actually pay must therefore be obtained in some manner other than through the issuance of such authorized securities."

**Illinois Commission Recognizes Distinction Between Refrigeration Service and Range and Heater Service.**—The Illinois Commerce Commission has reversed a previous order (Electrical World, Jan. 4, page 122) in which it directed that service to electric refrigerators should be rendered at the rate for heating and cooking. That decision was based upon a consideration of the character of electric refrigerator load and its effect upon the general system load. At a rehearing evidence was introduced by the Illinois Northern Utilities Company to show that its heating and cooking rate was devised to make electric service attractive where gas was not available and to develop load even if it were necessary to forego for a time a fair rate of return. A higher rate would exceed the value of the service and limit very materially the development of this class of business. It was the contention of the utility that the average customer can obtain refrigeration at reasonable rates through the purchase of ice and that the company is therefore under no obligation to render domestic refrigeration service on the same basis as electric heating and cooking. The commission accepted this view and found (1) that the schedule for domestic electric heating and cooking as charged by the petitioner is lower than might reasonably be charged if all factors and costs, including fixed charges, were included; (2) that the rates charged for domestic electric heating and cooking are apparently not a burden on the other classes of service; (3) that the voluntary offer of a rate that is less than compensatory for a certain class of service does not justify the commission in requiring the same rate to be charged for other classes of service; (4) that the rate earned by a domestic electric refrigerator under the domestic residence lighting rate, as charged by the Illinois Northern Utilities Company, is not excessive nor greater than the value of the service.

## Recent Court Decisions

**Theory That Loss from Fire Was Due to Electric Company's Negligence Found Speculative.**—In Dare vs. Atlantic City Electric Company damages were sought because of the alleged negligence of the company in controlling a fire of old lumber started on its premises and said to have spread to a barn owned by the plaintiff. The trial jury had found for the plaintiff, but the Supreme Court of New Jersey set the finding aside on the ground that it showed a high degree of speculation and was against the weight of evidence. (140 At. 249.)*

**Power of State Commission to Tax Water-Power Production Under Guise of Rental Denied.**—In the decision of the Chancery Court at Nashville, Tenn., denying the right of the Tennessee State Railroad and Public Utilities Commission to tax the Tennessee Eastern Electric Company one mill per kilowatt-hour on energy produced, as a condition of the issue to the company of a certificate of convenience and necessity, and also declaring the commission's fifty-year recapture clause illegal, as noticed under "News of the Industry" in the Electrical World for March 31 (page 673), the court said: "It was contended by counsel for the defendant commission that the one-mill tax sought to be imposed was in the nature of a rental for the use of the state's property. It is not claimed that the state owns any land which will be needed in the proposed development. The Legislature has not delegated to the commission any power or authority to rent out its properties for a long period of years at the price of one mill per kilowatt-hour or upon any other terms, even though it be said the state has the proprietary rights in the waters of such streams, a point not necessary to be decided. The powers given the commission are regulatory, relating to the public utilities and the conduct of their business, and it is without power to grant, bargain, sell, lease or otherwise dispose of or confer any sort of title to any property for the use of which the state might have a right to claim rentals." The recapture clause was declared confiscatory under the constitution of the state, which says that "no man's particular services shall be demanded, or property taken or applied to public use, without just compensation being made therefor."

---

*The left-hand numbers refer to the volume and the right-hand numbers to the page of the National Reporter System.

# News About Men of the Industry

**F. M. Ferrell** of the Kansas Gas & Electric Company, Wichita, has been made agricultural engineer for the company in the Newton district.

**J. H. McCombs**, formerly distribution engineer of the Georgia Power Company in Atlanta, has been appointed division superintendent of operation in Rome.

**J. R. English** has been appointed commercial manager for the Pennsylvania group of properties of the Associated Gas & Electric System, with headquarters at Johnstown.

**W. J. Cahill** has been appointed superintendent of power supply substations of the New York Power & Light Corporation, in charge of the operation and maintenance of the substations of the company.

**John Hurley** has been appointed publicity manager of the Winnipeg Electric Company, Winnipeg, Man., to succeed H. C. Howard, who has left the service of the company. Mr. Hurley was formerly a local newspaper man.

**Ward Chittenden** has been appointed manager for the Missouri Electric Power Company at Marshfield. Mr. Chittenden has been connected with the company since it acquired the Marshfield plant, and previous to that was engineer for the plant.

**Henry Oliver**, president of the Oliver Iron & Steel Corporation, Pittsburgh, Pa., has resigned to become chairman of the board of directors. **Bertram D. Quarrie**, formerly connected with the American Steel & Wire Company and with the Otis Steel Company, has been elected to succeed Mr. Oliver.

**Henry F. Schmidt**, consulting engineer of the Westinghouse Electric & Manufacturing Company, South Philadelphia, was made the recipient of the medal of the American Society of Naval Engineers for the best article submitted during the year 1927. In addition to the medal Mr. Schmidt was given an honorary life membership in the society and a cash prize for his paper entitled "Some Screw Propeller Experiments, with Particular Reference to Pumps and Blowers."

**R. W. Williamson**, manager of the western division of the Alabama Power Company, has been appointed general manager of the Gulf Power Company, with headquarters in Pensacola. Mr. Williamson entered the service of the Alabama Power Company in 1913 as draftsman, a position he held until he was transferred to the field, where he was engaged in construction and operating work. He left the employ of the Alabama Power Company in 1915 and was engaged in engineering work with the T. A. Gillespie Company of Parlin, N. J., and munition work for the British and United States governments. He re-entered the service of the Alabama Power Company in 1923 in the budget division, later going to the commercial department. After serving in this capacity he was made manager of the western division.

## *A. B. Day Becomes President in Los Angeles*

Addison B. Day, executive vice-president and general manager of the Los Angeles Gas & Electric Corporation for the past four years, has been named president of that utility to succeed William Baurhyte, whose resignation was announced in the March 31 issue of the Electrical World. Mr. Day is recognized as one of the leading executives in the public utility field on the Pacific Coast. His entire business career has been spent in the service of the utility which he will head. He entered the employ of the Los Angeles Light Company, predecessor of the Los Angeles Gas & Electric Corporation, in charge of the gas-stove department, in 1895, and has risen successively to the positions of bookkeeper, chief clerk in the gas department, chief clerk in the electrical department, manager of the appliance department, auditor, assistant secretary, manager of operation, general superintendent, vice-president and executive vice-president and general manager. He will retain his duties as general manager in connection with the presidency.

*A. B. Day*

**Charles L. Cadle**, general manager of the Rochester Gas & Electric Corporation, Rochester, N. Y., will sail for a twelve weeks' trip to Europe April 14 to inspect various power developments. Mr. Cadle was the guest of honor at a surprise party given at the Rochester Chamber of Commerce March 28. Among those attending were Robert M. Searles, president of the corporation; J. Clarence Collins, secretary and treasurer; Joseph P. Haftenkamp, assistant general manager, and Ernest C. Scobell, general auditor.

**James W. Cuthbert** of the Keene, N. H., division of the Public Service Company of New Hampshire has been transferred to the Manchester office as head of the department of public relations and safety.

**Eugene Mauer** has resigned as operating engineer for the Galesburg (Ill.) division of the Illinois Power & Light Company to become electrical engineer with W. A. Baehr Company, Chicago.

**M. C. Thompson**, formerly connected with the distribution engineering department of the Utica Gas & Electric Company, Utica, N. Y., has resigned to join the distribution engineering department of the Syracuse (N. Y.) Lighting Company.

**Glenn R. Trumbull** has joined the Columbia Gas & Electric Corporation as director of new business and merchandise sales for the Columbus (Ohio) group of properties. A native of Ohio and a graduate of Ohio State University, Mr. Trumbull received his early utility experience with the Union Gas & Electric Company of Cincinnati and later merchandising experience with several large utility companies.

**John S. Maloy** has been appointed distribution engineer of the West Penn Power Company to succeed M. W. De Merit, now assistant to the president. His connection with the company covers a period of ten years and started at the laboratory in Connellsville. Subsequently being transferred to Pittsburgh, he engaged in estimating and layout work. When distribution engineering became a separate department, in 1922, Mr. Maloy became one of the four engineers comprising the department.

**E. C. Conroy**, formerly assistant superintendent of distribution for the southwestern district of the Puget Sound Power & Light Company, has been transferred to the western district with headquarters at Bremerton, where he will be superintendent of distribution.

**Merritt C. Huse**, formerly assistant to C. J. Russell, vice-president in charge of the commercial department of the Philadelphia Electric Company, has been appointed sales manager of the company. A native of Manchester, N. H., and a graduate of the University of New Hampshire, Mr. Huse was associated with D. C. and William B. Jackson, consulting engineers of Boston and Chicago, from 1909 to 1917. It was in 1917 that he affiliated himself with the Philadelphia Electric Company. In his new position as head of the sales department he will be in charge of power sales, lighting sales, appliance sales and industry promotion work. Mr. Huse is a member of the Illuminating Engineering Society and is chairman of the wiring committee and a member of the industrial lighting, residential lighting and merchandising committees of the National Electric Light Association.

George E. Fuller, office manager and comptroller of the Worcester (Mass.) Electric Light Company, has been elected a vice-president of the organization. Mr. Fuller is widely known in New England central-station circles.

H. O. Gross, formerly connected with the engineering department of the United Gas Improvement Company, has been appointed manager of the Delaware division of the Philadelphia Suburban-Counties Gas & Electric Company with headquarters at Chester.

A. N. Kemp, vice-president of the California Bank of Los Angeles, has been elected a director of the Southern California Edison Company. Mr. Kemp was formerly vice-president in charge of finance of the Southern California Edison Company but he resigned five years ago to become an executive officer of the California Bank.

A. A. Brown has been appointed sales manager of the Oklahoma Gas & Electric Company with direct supervision over the investment and appliance departments. The identity of both departments will remain intact. Mr. Brown first joined the Oklahoma company in 1910 in the commercial department at Muskogee. From 1911 to 1917 he served as sales manager of the Northern States Power Company at St. Paul, but following military service he returned to the Oklahoma Gas & Electric Company as manager of the investment department in 1919.

Wells Stanley, formerly general manager of the Gulf Power Company, Pensacola, Fla., has been appointed manager of sales of the Alabama Power Company. Mr. Stanley became identified with the Alabama Power Company in 1914 as local manager at Huntsville, following the purchase by that company of the Huntsville Light, Railway & Power Company, of which he had been manager. He remained until 1917, when he was made manager of local operations with headquarters in Birmingham, later returning to Huntsville as manager of the Northern division. This position he held until his appointment in 1925 as general manager of the Gulf Power Company.

H. F. Boehner has resigned his position as assistant general manager of the Iowa-Nebraska Light & Power Company, Lincoln, Neb., and has organized the Midwest Refrigeration Company of Des Moines, Iowa, for the purpose of distributing General Electric refrigerators in 75 counties in the central part of Iowa. Mr. Boehner was originally interested in the Malvern Electric Company of Malvern, Iowa, which property was sold to the Continental Gas & Electric Corporation, and after operating at Malvern for the purchasers for a few years Mr. Boehner was named district manager of the Red Oak district, which embraced Malvern. Later he was transferred to the general office of the company as assistant general manager, which position he has held until the present time.

## *H. Carl Albrecht Receives New Appointment*

H. Carl Albrecht, who has been connected with the Philadelphia Electric Company since 1909, has been named assistant operating manager of the company. A native of Philadelphia and a graduate of the University of Pennsylvania, Mr. Albrecht entered the employ of the company as assistant to H. P. Liversidge, at that time superintendent of station electrical construction. In 1917 he became engineer of the station electrical design and construction division and in 1925 he was made manager of the purchasing, stores and transportation department. Mr. Albrecht has been active in the work of the National Electric Light Association, having served as chairman of the electrical apparatus committee in 1923, and also in the affairs of the A.I.E.E.

*H. C. Albrecht*

Philip S. Biegler, professor of electrical engineering at the University of Southern California for the past five years, has been appointed acting dean of the college of engineering just created at that institution. Professor Biegler removed to California five years ago after thirteen years of teaching at the Universities of Iowa, Illinois, Purdue and Washington State College and after a lengthy connection with the Commonwealth Edison Company in Chicago and the Washington Water Power Company of Spokane in an engineering capacity. From 1918 to 1921 he was associate engineering editor of Electrical World. The new dean has written extensively on educational problems, constant current regulators, deep well pumping and other engineering subjects. He is a member of the American Institute of Electrical Engineers, the Society for the Promotion of Engineering Education and of other professional and academic associations.

# Obituary

G. S. Williams, secretary of the Maryland Utilities Association, with headquarters in Baltimore, Md., died March 6.

Thomas A. Wilkinson, transmission engineer for the New England Public Service Company, died at his home in Augusta, Me., of cerebral hemorrhage April 2. Mr. Wilkinson was one of the pioneers in the industry, having first been connected with Westinghouse, Church, Kerr & Company for a number of years as head of the statistical department. After the dissolution of this organization he was affiliated for a time with the Ontario Hydro Commission. Subsequently he joined the Westinghouse Electric & Manufacturing Company to supervise the work of calculating transmission line constants for its book known as "Electrical Characteristics of Transmission Circuits." He has been transmission engineer for the New England Public Service Company for the past two years.

David H. Darrin, president of the Automatic Switch Company of New York, died March 29 at his home in New Rochelle, N. Y., of pneumonia. Mr. Darrin was many years ago identified with electric light and power plants in northern New York. Subsequently he entered the electric elevator manufacturing field and after his enterprise was absorbed by the Otis Elevator Company in the early nineteen hundreds he purchased an interest in the Automatic Switch Company, which had been incorporated in 1888. Mr. Darrin was one of the oldest members of the American Society of Mechanical Engineers and was a charter member of the old Electric Power Club.

Dr. Delos F. Wilcox, well-known authority on franchises and public utility valuation matters, died of pneumonia April 4 at New York Hospital after a brief illness. He was 55 years of age. A native of Monroe, Mich., Dr. Wilcox removed to New York in 1907 to become chief of the bureau of franchises of the Public Service Commission for the First District, which was then being organized. He resigned in 1913 to enter private practice as a public utility expert, but one year later he again took public office as Deputy Water Commissioner of the city of New York. He resigned from this position in 1917 to resume his private practice. As a public utility expert he was consulted by a large number of cities on franchise rate and valuation matters. He was the author of a large number of works dealing chiefly with the problems of city government and regulation of public utilities. Before removing to New York Dr. Wilcox engaged in work relating to improved city government, first in Cleveland and later at Grand Rapids and Detroit. He was a graduate of the University of Michigan.

# Financial and Statistical News

## *Utility Market Firm*
## *No Drastic Changes in Prices*

THE general market continued its upward spurt of the past few weeks so that interest continued to be centered in the more speculative issues. Few changes of any importance took place in the case of the common stocks of the electric light and power companies, though several did show gains. Particularly noteworthy for strength was the Brooklyn Edison Company, which advanced twelve points, reaching the highest mark in the history of the company, 245. Edison Electric Illuminating of Boston went up seven points and Public Service of New Jersey five. Many of the light and power preferred issues showed gains.

Radio Corporation touched the 195 mark, advancing from 169 during the week under review, and General Electric gained eight points, from 149 to 157.

## Canada's Output Increases 16.4 per Cent

The output of central electric stations in Canada during January totaled 1,317,736,000 kw.-hr., as compared with 1,131,212,000 in January, 1927. The increase is equivalent to 16.4 per cent. The report of the Dominion Bureau of Statistics shows that of the total, 1,297,783,000 are credited to water and 19,953,000 to fuel-using plants. Output generated from water power in the five economic areas shows a slight decline as compared with December, except in the Maritimes and British Columbia. In the former area, 10,880,000 kw.-hr. were produced, as compared with 10,686,000 in the preceding month and 9,335,000 in January, 1927. British Columbia records an increase from 91,875,000 in December to 93,340,000 in January. Production in that province has shown a steady advance in the past few years, the January total being the highest on record.

Both Ontario and Quebec record a decrease in output during January, as compared with the preceding month. The former had a production of 485,309,000 kw.-hr., as compared with 498,254,000 in December, while the latter's output totaled 611,728,000, as against 637,615,000 kw.-hr. in December. It is also noted that output in Ontario in January was less than in the same month in 1927. Output in the Prairie Provinces totaled 93,340,000 kw.-hr., a decrease of about 4,000,000 kw.-hr. from the preceding month, but compared with the total for January, 1927, there was an increase of about 19,000,000 kw.-hr.

## General Electric Records Another Profitable Year

ANOTHER profitable year is added to the creditable financial history of the General Electric Company. Although orders received during 1927 declined 5 per cent, to $309,784,623, net sales billed during the year were down almost 5 per cent and unfilled orders at the end of the year were 5 per cent lower. Net profits, however, increased almost 5 per cent. Price declines explain the decreases noted.

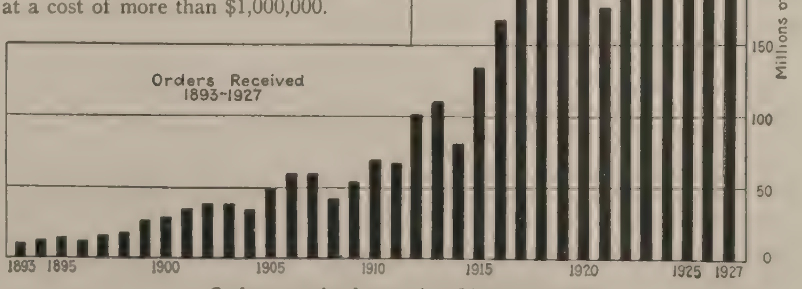
General Electric shows an unusually attractive earnings record over the past 25 years. Average profit available for dividends on common stock per share over a 25-year period was $14.84. For more than 28 years cash dividends have been paid continuously on the common stock, and from April, 1900, to and including 1926 the rate was $8 per share per year with an extra of $1 in 1917. In May, 1926, the old stock was split four for one and cash dividends of $3 per share per annum were paid on the new stock from July, 1926, to April, 1927, inclusive. Last July an extra cash dividend of $1 per share was paid, and at the same time the regular cash dividend was increased to $4. In addition liberal stock dividends have been paid from time to time.

The capacity of the company's operations was materially increased during 1927. A large addition to the switchgear factory was completed at Philadelphia at a cost of about $3,000,000. Furthermore, a high-power testing laboratory was completed in Schenectady, at a cost of more than $1,000,000.

The year was a profitable one also from the standpoint of the company's investments. An increase of nearly $19,000,000 is recorded in holdings, due partly to additional investments in associated manufacturing companies and in part to advances to enable the Electric Securities Corporation and the United Electric Securities Company to call bonds amounting to $13,440,000 and for other purposes.

Income accounts for the past two years follow:

| | 1927 | 1926 |
|---|---|---|
| Net sales billed | $312,603,772 | $326,974,103 |
| Costs, tax., deprec. | 276,454,003 | 289,878,335 |
| Net op. income | $36,149,768 | $37,095,768 |
| Other income | 15,395,918 | 12,561,526 |
| Total income | $51,545,687 | $49,657,295 |
| Interest | 284,486 | 436,512 |
| Gen. reserve | 2,461,712 | 2,548,284 |
| Net profit | $48,799,489 | $46,672,499 |
| Special dividends | 2,574,447 | 2,357,614 |
| Common dividends | 34,251,774 | 19,828,897 |
| Stock dividend | ........... | 7,210,810 |
| Surplus for year | $11,973,267 | $17,275,177 |



*Orders received covering 34-year period*

## Canadian Manufacturing Companies Issue Reports

Gross profits of the Canadian General Electric Company, Ltd., for 1927, after reserves and taxes, but before providing for depreciation, increased by 55 per cent, to $2,903,053, or $1,032,435 more than was earned in 1926. The net profits after writing off $800,000 for depreciation, as compared with $700,000 in 1926, amounted to $932,435 more than in 1926, or $2,103,053 available for the preference and common stocks. The sum of $599,042 was distributed in dividends during the year on the preference stock, leaving a surplus of $1,504,011, or nearly 16 per cent on the common stock. The same amount of money was paid in dividends in 1926 on the preferred stocks.

The financial report of the Canadian Westinghouse Company, Ltd., for the year ended Dec. 31, 1927, shows a further substantial increase in profits, with net earnings for the year equal to 23.04 per cent on the company's outstanding capital stock, as compared with 18.3 per cent in 1926 and 14.4 per cent in 1925. Operating profit for the year amounted to $2,551,188, as compared with $1,796,741 in 1926. Deduction of depreciation at $240,000, Dominion taxes at $187,000 and pension fund at $50,000, left net earnings at $2,074,188, against $1,366,741 in the preceding year. Dividends paid during the year amounted to $838,116, and patent, etc., reduction of $499,999 left a surplus for the year of $736,073.

## German Electrical Industry

The latest census of the electrical industry in Germany was taken in 1925, according to a recent report received from one of the ELECTRICAL WORLD'S foreign correspondents. The returns, covering 176 generating and 194 manufacturing establishments, are summarized in the table above.

ELECTRIC POWER & LIGHT PAYS INITIAL DIVIDEND.—Directors of the Electric Power & Light Corporation have declared an initial quarterly dividend of 25 cents per share on the common stock, no-par value, payable May 1 to holders of record April 14.

RECENT LISTINGS.—The New York Stock Exchange has authorized the listing of 5,162 additional shares of common stock, class A, of the General Gas & Electric Corporation, without par value, on official notice of issuance and payment in full, making the total amount applied for 350,909 shares. There have been placed on the Boston Stock Exchange list first mortgage 5 per cent twenty-year gold bonds of the Oklahoma Power & Water Company to the amount of $4,500,000.

HARTFORD ELECTRIC TO REDUCE PAR OF STOCK.—The directors of the Hartford Electric Light Company, Hartford, Conn., met March 27 and voted to recommend to stockholders a par value reduction in stock from $100 to $25. This is advised by the directors to obtain a wider distribution of ownership. At present the capital structure has 180,000 shares, which under the plan would become 720,000 shares. New certificates for shares will be issued as soon as the recommendation is approved by a majority of the stockholders.

TRI-CITY PASSES PREFERRED DIVIDEND.—The Tri-City Railway & Light Company, Davenport, Iowa, has passed the preferred dividend due April 1 this year. The last payment was 1½ per cent, paid Jan. 2.

ELECTRIC VACUUM DECLARES EXTRA DIVIDEND.—The Electric Vacuum Cleaner Company, Inc., declared an extra dividend of $1 in addition to the regular quarterly dividend of $1 a share on the common stock.

BUFFALO, NIAGARA & EASTERN STARTS CONSOLIDATION OF SUBSIDIARIES.—As the first step in consolidating the subsidiaries, stockholders of the Buffalo, Niagara & Eastern Power Corporation, March 19 voted to authorize an issue of 500,000 shares of first preferred stock without par value. The stock will be entitled to cumulative dividends at the rate of $5 a share annually. Plans call for the issuance soon of not more than 350,000 shares of the new stock to acquire by exchange or to provide funds for redemption of preferred stocks of the Niagara Falls Power Company, Niagara, Lockport & Ontario Power Company and the Tonawanda Power Company, three of the subsidiaries to be consolidated.

PENN CENTRAL SHAREHOLDERS GIVEN RIGHTS.—Holders of $5 series preferred stock of record April 2 will be given the right to subscribe on or before May 6 at $45.50 per share for a new series of preferred shares of no-par value, designated as $2.80 series, to the extent of 15 per cent of their holdings. The unsold portion of the 25,000 shares of $2.80 series preferred stock will be offered to the public at $47 per share.

## April Issues Total $94,775,000

Six electric light and power companies issued new securities during the first week in April to the amount of $94,775,000. The American Gas & Electric Company was responsible for $50,000,000 of the total in the form of 5 per cent gold debentures priced at 101 and accrued interest, to yield about 4.95 per cent. Proceeds will be used in connection with the redemption on May 1, 1928, of all of the $46,904,000 6 per cent gold debenture bonds of the company now outstanding with the public. Another sizable offering of 5 per cent gold debentures was made by the New England Power Association, a piece of financing involving a total of $25,000,000.

First and refunding mortgage gold bonds of the Gulf Power Company were offered at 99 and interest, to yield about 5.06 per cent. This issue amounted to $2,500,000. Two new offerings were made by the Central States Edison Company—one in the form of first lien 5½ per cent gold bonds, series A, amounting to $1,350,000, and the other in the form of three-year 5½ per cent convertible gold notes, priced at 98½ and interest, amounting to $675,000.

The North Continent Utilities Corporation issued 12,500 shares of 7 per cent cumulative preferred stock at $100 per share and accrued dividends, proceeds from the sale of which will be used for extensions and betterments.

The Minnesota Power & Light Company made an offering of first and refunding mortgage gold bonds, 4½ per cent series, amounting to $14,000,000, the price being 97¼ and interest, yielding 4.64 per cent. These bonds were dated May 1, 1928, and mature May 1, 1978. Upon completion of this financing there will be $24,700,000 first and refunding mortgage gold bonds and $7,747,000 underlying divisional bonds outstanding.

# Utility Offerings in 1928 Total $330,000,000

DURING the first three months of 1928 the electric light and power companies of the country issued new securities to the amount of $330,406,852, as compared with $486,634,000 for the corresponding period of 1927. The month of March contributed $128,301,352 to this total, a figure which indicates an increase of $32,000,000 over March, 1927, and of $25,000,000 over February, the preceding month.

The largest individual offering in March was made by the Engineers Public Service Company in the form of convertible preferred stock, a piece of financing involving a total of $32,000,000. Proceeds will be used to retire the 311,662 shares of $7 dividend preferred stock. Engineers Public Service was not the only utility that took advantage of favorable conditions to replace old issues bearing high interest rates with new issues yielding lower returns. The Iowa Power & Light 4½ per cent issue replaced 6 per cent and 5½ per cent bonds; Utah Power & Light's five-and-a-half-million-dollar issue replaced a similar amount of 6s outstanding; proceeds from the twenty-three-million-dollar issue of the Metropolitan Edison Company retired various 5 and 6 per cent issues and the Memphis Power & Light offering of 4½ per cent bonds refunded a 6 per cent issue.

With the exception of one small issue the new financing was all of a long-term nature. The average yield dropped to 5.09 per cent in March.

## *Security Issues of Electric Service Companies in March*

| Name of Company | Amount of Issue (Par Value) | Period Years | Class | Purpose | Interest Rate | Price | Per Cent Yield |
|---|---|---|---|---|---|---|---|
| Rochester Gas & Electric Corp. | $6,000,000 | 49 | General mortgage gold bonds, series D | To reimburse for cost of extensions and additions | 4½ | 99½ | 4.52 |
| Interstate Public Service Co. | 12,554,000 | 30 | First mortgage and refunding gold bonds, series F | To reimburse for refunding bonds and for other corporate purposes | 4½ | 94½ | 4.85 |
| Oklahoma Power & Water Co. | 4,500,000 | 20 | First mortgage gold bonds, series A. | To provide a part of the purchase price of properties acquired | 5 | 96½ | 5.30 |
| National Power & Light Co. | 10;314,852 | .. | Cumulative preferred stock | General corporate purposes | 6 | 102 | 5:88 |
| Iowa Power & Light Co. | 6,000,000 | 30 | First mortgage gold bonds, series A | To retire bonds, for additions and extensions and for other corporate purposes | 4½ | 95¼ | 4.80 |
| San Antonio Public Service Co. | 7,500,000 | 30 | First mortgage and refunding gold bonds, series B | To finance acquisition of new properties and to reimburse company for other capital expenditures | 5 | 97½ | 5.16 |
| Utah Power & Light Co. | 5,500,000 | 16 | First lien and general mortgage gold bonds | To retire bonds | 4½ | 96¾ | 4.79 |
| Metropolitan Edison Co. | 23,000,000 | 40 | First mortgage gold bonds, series D. | To retire bonds bearing higher rates of interest and for additions and betterments | 4½ | 99½ | 4.52 |
| Memphis Power & Light Co. | 2,275,000 | 50 | First and refunding mortgage gold bonds, series C | To retire bonds | 4½ | 96¼ | 4.70 |
| Orange & Rockland Electric Co. | 1,250,000 | 30 | First mortgage gold bonds | To retire all present outstanding bonds and notes, to reimburse for expenditures on construction and for other corporate purposes | 5 | 99½ | 5.03 |
| United Public Utilities Co. | 3,750,000 | 19 | First lien gold bonds, series B | To acquire securities of subsidiaries | 5½ | 97¾ | 5.70 |
|  | 3,307,500 | .. | Preferred stock | ........ | 6 | 94½ | 6.35 |
| American Commonwealths Power Corp. | 4,750,000 | .. | First preferred stock | To acquire stocks of other companies and for other corporate purposes | 6½ | 95 | 6.85 |
| Engineers Public Service Co. | 32,000,000 | .. | Convertible preferred stock | To retire preferred stock | 5 | 100 | 5 |
| Iowa Public Service Co. | 1,500,000 | 40 | Gold debentures | For acquisition of stock of another utility and for other corporate purposes | 5 | 95 | 5.30 |
| North Continent Utilities Corp. | 3,500,000 | 20 | First collateral lien and refunding gold bonds, series A | To retire outstanding bonds or to reimburse for expenditures on additions and improvements already made and for other corporate purposes | 5½ | 97 | 5.75 |
| Great Western Utilities Corp. | 600,000 | 5 | First lien and collateral trust gold bonds, series A | Acquisition of properties, to retire indebtedness and for other corporate purposes | 6 | 100 | 6 |
| Total | $128,301,352 |  | Rights | $32,595,000 |  |  |  |
| Total amount actually realized | 126,088,078 |  | Total financing for March | $158,683,078 |  |  |  |

# Business News and Market Conditions

## Underwriters Report on Armored Cable

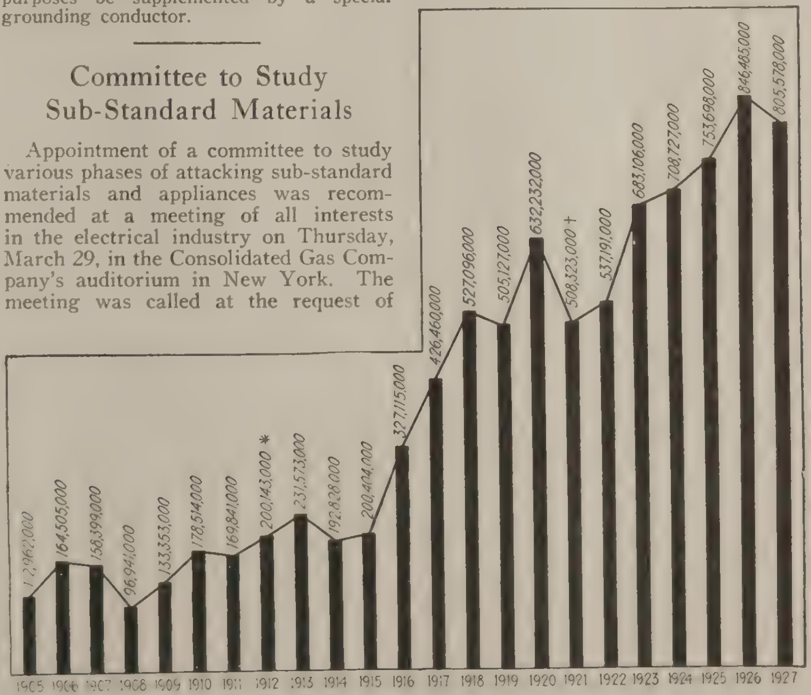
A. R. Small, vice-president the Underwriters' Laboratories, New York City, has issued a report covering the work of the Laboratories on armored cable to determine the various properties of armored cable using the new standard of 0.025 in. for thickness of strip instead of 0.034 in. as previously. The report is as follows:

> The manufacturers of armored cable have approved in principle the recommendations of the report of Underwriters' Laboratories made as a result of research undertaken at their instance and request, pursued for upward of a year. The object of this research was to determine the various electrical and physical properties of armored cables in relation to the use of the product under the conditions of the National Electrical Code.
>
> In addition to laboratory work, the research included studies, at the factories of all producers, of machines, equipment and methods in the manufacture, test and packing for shipment, and extensive studies in the field of contractors' practices in the installation and use of the product. This latter phase of the research, together with the provisions of the National Electrical Code, provided the basis for determining what are the necessary and desirable electrical and physical properties of armored cable.
>
> Various determinations reached are judged of especial interest at this time, viz., the thickness of strip and the conductivity or, inversely, the resistance, in runs of the cable and at outlet fitting connections. The detailed results of tests described in the report covering the physical properties of resistance to tension and crushing loads give conclusive evidence of acceptable values in these properties of the product to the industry as a whole. These results seem to dispose of the questions raised in the minds of inspection authorities and of contractors covering the new standard for thickness of strip of 0.025 in. instead of 0.034 in. in effect prior to 1925.
>
> In laboratory tests many samples representative of all makes and designs of armored cable were subjected to electrical burnout and overload current tests to determine the characteristic performance when abnormal conditions exceeding those contemplated in the National Electrical Code rules were imposed. The report shows that cable made of 0.025 strip does not convey fire to the outside when burnouts of conductors take place with the conductors loaded up to 100 per cent in excess of National Electrical Code standard fusing for the circuits involved.
>
> Determinations of resistance and conductivity developed the interesting point that over-heating, when carrying grounding currents, would not occur with loads greatly in excess of those appropriate for the fusing of the circuits, and, further, that the actual conductivity of the metal strip of armor varied according to the attitude of the armor as installed; at bends or when the cable was in other than the lying-straight position the resistance dropped to values much less than obtained when specimens were lying straight. This phenomenon is due to the contacts made by the edges of the strip in the convolutions which form the armor with the surface of the adjoining strip. These contacts are better electrically on account of the pressure produced by the curved attitude of the armoring.
>
> It was shown that it will be feasible to specify and obtain such a maximum value for resistance of armor when in the lying-straight position as to produce no dangerous rise in temperature in the metal when it is called upon to carry grounding currents much in excess of those for which the circuit wires are properly fused. All manufacturers in the industry are now co-operating with the staff of the laboratories relative to the installation of equipment and test methods to control this factor on the entire output.
>
> The report thoroughly disposed of questions which have been raised concerning the resistance of connections at outlet fittings. All usual makes and types of terminal fittings with different standard makes and types of outlet boxes were tested with various combinations and sizes of standard armored cable. In general, the data of the report show that the resistance across an outlet including two fittings is no greater than the resistance of a run of 6 in. of the cable itself. These results were the considerations leading the committee on wiring methods (article 5 of the National Electrical Code) to take no action on the proposed recommendation that the conductivity and reliability of connections of armored cable for protective grounding purposes be supplemented by a special grounding conductor.

## Committee to Study Sub-Standard Materials

Appointment of a committee to study various phases of attacking sub-standard materials and appliances was recommended at a meeting of all interests in the electrical industry on Thursday, March 29, in the Consolidated Gas Company's auditorium in New York. The meeting was called at the request of various interests by the Electrical Board of Trade of New York, Inc., whose chairman, Charles L. Eidlitz, opened the meeting and turned over the chair to T. H. Joseph, who called on various members to offer their suggestions. Reinspection of installations was suggested as one way to stop the use of non-approved material, but J. C. Forsyth of the New York Board of Fire Underwriters said the cost was prohibitive. H. R. Sargent, speaking for the manufacturers, said that while some manufacturers were for quality and approved material only it was impossible to control the production and standards of all the manufacturers. Harry Kirkland of the Society for Electrical Development referred to the city ordinances of Portland, Ore., and Louisville, Ky., where none but approved material could be offered for sale. In discussing the passage of a similar ordinance in New York City objection was made by representatives from adjoining territories in Long Island, New Jersey and Westchester County, who said that a local ordinance would have the effect of dumping the non-approved products in

### Trend of Electrical Sales



Combined Electrical Sales of Allis-Chalmers Manufacturing Company, Crocker-Wheeler Electric Manufacturing Company, General Electric Company, Graybar Electric Company, Western Electric Company and Westinghouse Electric & Manufacturing Company

(a) Munitions sales during the war years and non-electrical sales not included.

(b) Sales of any one of the companies do not include purchases from any of the other companies listed.

*Fort Wayne, Sprague and National added to General Electric sales.

†Southwest General Electric added and International General Electric omitted from General Electric sales.

their respective localities. It was suggested that relief be sought through State legislation. Whether to remedy the situation through State legislation, label registration, complete fire insurance inspection or some other way will be determined by a committee which will represent all branches of the industry.

## N.E.M.A. Develops Code of Business Conduct

Through its board of governors the National Electrical Manufacturers' Association has indorsed a code of business conduct. This code, as developed by the committee on code of ethical and sound merchandising principles, was presented to the policies division meeting in Chicago by N. A. Wolcott, chairman of the committee, and will appear shortly in printed form. The more specific portions of the code are as follows:

The electrical manufacturers indorse the principle of a one-price policy.

A request for competitive prices on the part of a buyer involves definite obligations toward all bidders. The electrical manufacturers indorse as in the interest of sound, ethical and economic relations between buyer and seller the following principles to apply to competitive bidding under any specific inquiry:

That the bids be considered as confidential information between buyer and bidder until all bids are in and the buyer has placed the business.

That bidders exchange, where practicable, full information regarding their bids after the business is placed.

Where specifications call for various items involving different types and classes of apparatus, the relative merit of the different bids is best determined and freedom of choice on the part of the buyer promoted if each bidder quotes segregated prices at which any individual item would be accepted.

# Market Conditions

STEADY buying of general supplies is reported in the New England district. Orders for heavy industrial equipment and central-station supplies are predicted for the coming months, though at present the market is quiet. Building supplies are in good demand. In the Eastern district satisfactory sales continue. A New York power company placed an order for $300,000 worth of substation apparatus. There is an increasing number of new prospects now in the market for motor equipment. A manufacturer of appliances reports excellent business.

In the Southeast the industrial field is active. A textile plant in Tennessee purchased considerable equipment, including a 3,000-kw. turbo-generator; two 1,500-kw. turbines also were ordered for the use of tobacco plants in the Carolinas, and a tannery in Georgia purchased 31 motors. The demand for building materials is steady in St. Louis, and good sales of electric ranges are reported. March business in the Middle West improved over that of January and February. On the Pacific Coast buying by industrial plants is active. A paper plant at Grays Harbor, Wash., purchased $30,000 worth of equipment, a paper plant at Port Townsend ordered $10,000 worth of transformers and a Nevada mining company bought $17,500 worth of equipment. A decided improvement in motor sales is reported by Seattle concerns.

### *Lead Sales Active—Little Copper Buying Recorded*

The only metal in the non-ferrous group that enjoyed an active market is lead. Buying was particularly brisk at the higher prices established on Monday. Following a phenomenally big week from the standpoint of volume of sales the copper market quieted down and sales have been very light. Zinc continues dull, though prices are a little better. Tin is inactive with little net change in prices.

NEW YORK METAL MARKET PRICES

| | Mar. 28, 1928 Cents per Pound | April 4, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 13 90 | 14 0 |
| Lead, Am. S. & R. price | 6 | 6.10 |
| Antimony............ | 9¾ | 9½ |
| Nickel, ingot.......... | 35 | 35 |
| Zinc spots............ | 6.046 | 6.075 |
| Tin, Straits.......... | 53 | 53¼ |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper wire price April 4, 1928, 16 cents.

### *New England Sales Continue at Steady Rate*

Sales of general supplies is in steady volume in the New England district. Orders for heavy industrial equipment and central-station supplies are predicted for the coming months, though at present the market is quiet. Small-motor sales are normal. Orders recently have been received for motors to replace group drive in several factories, among which are noted two shoe factories in southern New Hampshire and a prominent rubber factory in eastern Massachusetts.

New construction supplies are in good demand. With a large amount of new building to be done in the district, the volume of supplies to meet this need gives promise of showing a marked increase over that of last year. Wire, wiring devices, cable and conduit are moving steadily, outside work is advancing, floodlighting systems are receiving attention, and street-lighting projects are progressing. A plan has been proposed to establish a "whiteway" in Haverhill, Mass. Electric heating furnace sales are encouraging. A prominent manufacturer reports for the first quarter sales of seventeen pot furnaces, four box type units and three special types, aggregating about 750 kw. The Holyoke Water Power Company has received permission from the War Department to build a hydro-electric plant and plans have been prepared for a development of 40,000 hp. from four units. The United States Finishing Company, Providence, R. I., plans an addition to its textile mill, to cost $100,000.

### *Industrial Field Active in Southeast*

Such activity as is noted in the Southeast is in the industrial field. Central-station buying is considerably off. Contracts were let in connection with a textile plant in Tennessee and orders were placed for a 3,000-kw. turbo-generator and auxiliary equipment, $125,000 worth of wiring supplies, and oil circuit breakers amounting to $12,000. A switchboard order for $30,000 was recently placed in connection with the same textile plant. A small turbine and motor equipment were purchased by a Carolina textile plant at a cost of approximately $20,000. Two 1,500-kw. turbines also were ordered for use of tobacco plants in the Carolinas. A tannery in Georgia ordered 31 motors aggregating 465 hp. for use in a rebuilt plant. Building contracts which will be let in a few days include one for a silk mill in Tennessee, the electrical materials on which will approximate $15,000, and another on a bleachery in South Carolina, wiring materials transformers and motor equipment on which will be about $30,000.

The Georgia Power Company has purchased the privately owned distribution system at Lyerly and will extend its 38,000-volt transmission line a distance of 7 miles and will install a 150-kva. transformer substation to serve that town. The Georgia Power Company also has purchased the municipally owned distribution system in Bowman and will install a 150-kva. transformer substation and revamp the system for three-phase operation.

Construction news is as follows: The Southeast Power Company has acquired the municipal power plant at Nashville, Ga., and plans installation of Diesel engine-generator and other equipment. The Mississippi Power & Light Company will install a distribution system at Myrtle, Miss. The Chatham Manufacturing Company, Elkin, N. C., is building an addition to its textile mill to cost $85,000. The Duke Power Company plans a substation at Marion, N. C., to cost $50,000. The Cleveland Cloth Mills Company, Shelby, N. C., will build an addition to cost $200,000.

The Chilhowee Mills Company, Athens, Tenn., will build an addition to its textile mill, to cost $70,000. The Dixie Stock Yards, Memphis, Tenn., plan a packing plant to cost $100,000. The Virginia Electric & Power Company plans a substation at Norfolk, Va., to cost $250,000. The Central Atlantic Service Corporation, 20 Broad Street, New York, plans an ice plant at Pulaski, Va., to cost $100,000. The Carolina Power & Light Company has authorized surveys for a transmission line from Sanford to Broadway, N. C. The Southern Public Utilities Company will build a transmission line to Walnut Cove, N. C. The Tennessee Electric Power Company plans a transmission line from Nashville, Tenn., to Muscle Shoals, to cost $700,000. The Northern Virginia Power Company plans a transmission line to Kabletown, W. Va. Montgomery, Ala., and Pineville, W. Va., will install street-lighting systems.

## *Satisfactory Sales Continue in Eastern District*

Both central-station and industrial business continue active in the Eastern district. While orders are on a reduced basis, the gross volume of transactions compares favorably with sales for the same period last year. A New York power company has placed an order for substation apparatus amounting to about $300,000, while a New Jersey utility has been active in ordering substation and switching equipment. Northern New York power interests are becoming more noticeable in the market, and with comparatively small sales from this quarter up to the present time it is expected that satisfactory business will ensue. A Connecticut central-station company has been making purchases of transformers, switching apparatus and other substation equipment to a total of $90,000, and the demand is growing stronger from utilities in that section. Increasing industrial activity in certain lines is leading to corresponding advance in electrical equipment orders. There is a healthy tone to the growing inquiries for motors and kindred apparatus for paper mills, chemical plants, iron and steel works, and textile mills. A leading manufacturer of industrial motors comments upon the increasing number of new prospects now in the market for equipment, with each week developing a sizable quota of such account. Sales of automatic timing switches for plant service also show improvement. A manufacturer of sewing machines in New Jersey has placed an order for control and kindred apparatus with a prominent maker to an amount of $20,000. A paper mill has asked bids on a complete line of equipment for a new plant at Tacoma, Wash., and will soon place contracts. A chemical company at Syracuse, N. Y., is making commitments for a plant at Hopewell, Va. Another such concern at New York will purchase a considerable amount of equipment, including electric cranes, for a synthetic gypsum plant at Tampa, Fla. Newark, N. J., has asked bids for a signal system to cost about $25,000.

A prominent manufacturer of electric appliances reports excellent business in that line, with sales records for the first quarter of 1928 exceeding the figures for the corresponding period or for any other quarter of last year. Jobbers have been active purchasers, with particularly heavy demand from this quarter at Philadelphia and Harrisburg, Pa. Electric elevator business is decidedly good in the metropolitan district at the present time, with inquiries indicating continuance. The call for electric welding apparatus has been lagging for several weeks, but early revival is in sight. Electric railway business continues to show improvement. New York subways are expected to be in the market for motor apparatus for the new Flushing, L. I., extension at an early date. Business with steam railroads is on a reduced basis. Wire and cable sales have been at a low point, but current inquiries point to more sizable commitments within a short time.

Construction activities in the Eastern district include the following: The Bronx Gas & Electric Company plans a substation on Laconia Avenue to cost $100,000. The New York Central Railroad Company is asking bids until April 13 for railway motors and multiple-unit control equipment. The Signal Corps Procurement District, Governors Island, will receive bids until April 12 for 24 lightning switches (Circular 140). The Public Service Electric & Gas Company plans a switching station at Metuchen, N. J., and a substation at Princeton, N. J. The Great Lakes Portland Cement Company, Buffalo, N. Y., plans a mill near Cleveland, to cost $1,000,000. The Bethlehem Shipbuilding Corporation, Baltimore, Md., will construct an addition to cost $1,800,000. The Southern Light & Power Company has purchased the Millington Electric Light & Power Company, Millington, Md., and will build transmission lines in Queen Anne County. Patapsco Power, Light & Mineral Company, Marriottsville, Md., plans a feldspar mining mill to cost about $85,000. The United States Engineer, Pittsburgh, Pa., will receive bids until April 11 for two hydraulic turbines (Circular 358). The Board of District Commissioners, Washington, D. C., is asking bids until April 12 for six transformers for the new McKinley technical high school. The General Purchasing Officer, Panama Canal, Washington, D. C., will receive bids until April 19 for electric fans, etc. (Panama Schedule 1869).

## *March Business Improved in Middle West*

March business in the Middle West improved over that of January and February. Sales during the first quarter of the year were not quite up to the expectations expressed at the beginning of the year. Apparently there is no room for apprehension as to conditions. Building activity is getting under way. Utility companies continue active in construction work. An order placed for the construction of a substation amounted to $50,000, and another order called for 46 distribution transformers from 37½ kva. to 450 kva. Jobbers' sales are normal. Considerable municipal business is being obtained and sales are expected to improve.

Construction projects are as follows: The Udell Printing Company, Chicago, plans a new plant to cost $300,000. The Consolidated Sign Company, Battle Creek, Mich., plans a new plant to cost $100,000. The Kalamazoo Vegetable Parchment Company, Kalamazoo, Mich., plans an addition to cost $900,000. The Consumers Power Company, Jackson, Mich., plans a 35,000-hp. hydro-electric plant in the Mecosta-Newaygo district, to cost $1,500,000. The Michigan Rubber Company, Owosso, Mich., plans an addition to cost $100,000. Montpelier, N. D., plans a light and power system to be furnished by the Otter Tail Power Company. Christ Hospital, Cincinnati, Ohio, plans a power plant and laundry, to cost $350,000. Sioux Falls, S. D., is arranging bonds for $100,000, for improvements in its municipal power plant. The Modine Manufacturing Company, Racine, Wis., plans an addition to its automobile radiator plant, to cost $100,000. Cedar Rapids and Jewell, Iowa, and Neenah, Wis., plan ornamental lighting systems.

## *Buying by Industrial Plants Active on Pacific Coast*

Industrial plant buying marked the activity on the Pacific Coast. Such orders as two 1,000-kva. control switchboards, totaling $30,000, for a paper plant at Grays Harbor, Wash., power transformers totaling $10,000, for a Port Townsend paper plant, $4,000 worth of synchronous motors for ice machine service, a 187-kva. waterwheel generator, valued at $3,500, for the porcelain plant of a spark plug manufacturer, a 125-hp. slow-speed synchronous motor, valued at $4,500, for a cement mill, and a 200-hp. synchronous motor, valued at $2,500, for a Nevada mining company. Another Nevada mining company ordered two storage battery General Electric locomotives, which, with nine transformers, 150 kva. and 200 kva., motor-generator set, lightning arresters and accessories, comprises an order totaling $17,500. Mining business is indeed brisk. Orders include $2,000 worth of wiring material for a gold dredger, a similar assortment for Alaska mines, and a large shipment to Mexico comprising 30 motors from 3 hp. to 75 hp. and three 75-kva. transformers, totaling $12,000. Power company orders have included one carload of 10-kv. pin-type insulators, valued at $5,000, for the Fresno district, $3,000 worth of weatherproof wire, $1,000 worth of hardware for the Turlock irrigation area, and 200 ranges, valued at $20,000, principally for the Tulare and northern California areas.

A decided improvement in motor sales is reported by Seattle concerns and includes 50 machines, from 125 hp. down, to a pulp and paper mill in the Grays Harbor district, 25, from 30 hp. down, to a pulp mill in Bellingham, and approximately 100 small motors from 15 hp. down, mainly for irrigation and orchards and the remainder divided between woodworking and industrial sources. The city of Seattle is expected to call for bids for furnishing and installing network protectors and cable material to cost about $200,000 including installation. An ordinance is before the Bremerton city council providing for the installation of a street lighting system to cost about $22,000.

Construction projects are as follows: The Pacific Fruit Express Company, San Francisco, will build a refrigerator car repair shop at Tucson, Ariz., to cost $225,000. Los Angeles plans a substation at Venice, to cost $80,000. The Western Oil & Refining Company, Martinez, Calif., plans a new plant to cost $350,000. The Mechow-Pateros Growers Association, Pateros, Wash., plans a cold storage plant to cost $90,000. The Wenatchee Produce Company, Wenatchee, Wash., plans a cold storage plant to cost $100,000. The Great Northern Railway Company, St. Paul, Minn., plans a repair shop for electric locomotives at Wenatchee, Wash., to cost $100,000. The Puget Sound Power & Light Company, Seattle, Wash., plans transmission lines in Louis County, to cost $80,000. Montesano, Wash., will install ornamental lighting system. The British Columbia Electric Power & Light Company, Victoria, B. C., plans a distribution station to cost $250,000.

### *Building Material Demand Steady in St. Louis*

Important orders in the St. Louis district include four motors, amounting to $6,000 for the oil district, substation equipment for southern Illinois amounting to $35,000, and four generators, to cost $10,000, for connection with Diesel engines. Jobbers and retail dealers report business in building and line construction materials holding up to last year's level, also a good demand for electric ranges.

Construction projects are as follows: The Varnell Lumber Company, Hampton, Ark., plans a local power plant and system. The Kansas State Industrial Reformatory, Hutchinson, Kan., plans an addition to power plant to cost $50,000. The Waxide Paper Company, Kansas City, Mo., plans a mill at St. Louis, to cost $250,000. The Kansas City Fibre Box Company, Kansas City, Mo., plans an addition to cost $750,000. The Great Atlantic & Pacific Tea Company, New York, plans a baking plant at St. Louis, to cost $650,000. The B. F. Goodrich Company, Akron, Ohio, plans a factory branch and distributing plant at St. Louis, to cost $100,000. The Great Plains Mill & Elevator Company, Enid, Okla., plans a new flour mill, to cost $200,000. The Syndicate Power Company, Abilene, Tex., plans a hydro-electric plant on the Colorado River. The San Antonio Tanning Company, San Antonio, Tex., plans a plant to cost $100,000. The Ewauna Box Company, Klamath Falls, Ore., plans a branch mill at San Benito, Tex., to cost $200,000. Amite, La., Muskogee, Okla., and Bossier City, La., plan ornamental lighting systems.

# Activities of the Trade

## Standard Underground Makes Organization Changes

A. B. Saurman, formerly vice-president and general sales manager of the Standard Underground Cable Company, Division of General Cable Corporation, Pittsburgh, has been made vice-president and consulting general sales manager and will continue his headquarters at the general offices in Pittsburgh, upon his return from the South, where he has been for some time on account of ill-health. Harold P. Childs has been made general sales manager. Mr. Childs was formerly vice-president in charge of sales and advertising for the Servel Corporation and previous to that served with the General Electric Company in the executive office under Anson Burchard, vice-chairman of the board, and J. R. Lovejoy, vice-president.

## Hydroil Sales Corporation Changes Name

The Hydroil Sales Corporation of Lebanon, Ind., having purchased a factory and broadened its operation to include manufacturing as well as engineering and selling, has changed its name to the Hydroil Corporation. The company in making this change felt that the new name conveys a more complete understanding of its operation.

## Celoron Company Builds New Laboratory

A new laboratory has just been completed by the Celoron Company, division of the Diamond State Fibre Company, Bridgeport, Pa. The company manufactures virtually all its own raw material, making its own paper, resins, etc. The new laboratory has been equipped with facilities for making electrical, physical and chemical tests on its products both during the process of manufacture and as a finished article, and also for doing research work. The laboratory building is a two-story brick structure 42 ft. by 53 ft.

## Edison Appliance Appoints Simplex Division Manager

Following the acquisition of the wall outlet appliance business of the Simplex Electric Heating Company, Cambridge, Mass., by the Edison Electric Appliance Company, Inc., Chicago, the Edison company announces that H. K. Dewees will be manager of the Simplex division at 5600 W. Taylor Street, Chicago. Mr. Dewees was formerly assistant appliance division manager of the Edison company. He is succeeded by J. Eugene Armes of the "Hotpoint" appliance sales division of the Edison company. The sale of the wall outlet appliance business of the Simplex company was announced in the Feb. 11, 1928, issue of the ELECTRICAL WORLD.

The Simplex business will retain its own identity and virtually the same sales personnel. All the present appliances in the Simplex line will be continued with the probable addition of some new items in the near future. The nation-wide system of service stations which the Edison Appliance company maintains will be available to all Simplex dealers.

THE ERICSON MANUFACTURING COMPANY, Cleveland, manufacturer of "C & E" safety handles, etc., is now marketing an insulated guard which consists of a metal framework to which the necessary thickness of rubber is added. The guard is primarily for use with the "C & E" safety handle made by the company, but also may be used where any loose guard is required.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY announces that William M. Bradshaw, manager of the meter engineering department, and 39 of his engineers have been transferred from the main plant of the company at East Pittsburgh to the Newark works at Plane and Orange Streets.

THE MARTINDALE ELECTRIC COMPANY, 1260 West Fourth Street, Cleveland, announces its new double-duty commutator stones.

THE WORTHINGTON PUMP & MACHINERY CORPORATION, 115 Broadway, New York City, announces the removal of its executive offices and export and New York district sales department to 2 Park Avenue, New York City, on or about April 1. The company also has moved its head office sales and advertising departments to the Harrison plant of the corporation, located at 421 Worthington Avenue, Harrison, N. J.

THE IDEAL COMMUTATOR DRESSER COMPANY, Sycamore, Ill., has opened a new branch office at 182 Purchase Street, Boston. New sales representatives recently appointed are as follows: C. B. Keck, Cleveland; F. D. Lawrence Electric Company, Cincinnati; O. T. Hall, Maryland, District of Columbia and the eastern part of Virginia; G. A. Brewer, Connecticut, and De-Moss Fox & Company, Michigan and Toledo, Ohio.

THE DAMPNEY COMPANY OF AMERICA, Hyde Park, Boston, announces that the sale of its "Apexior" protective coatings for power plant equipment will be handled in North Carolina, South Carolina, Florida, Tennessee, Georgia, Alabama, Mississippi and Louisiana by Nevill & Cleary, Inc., Candler Building, Atlanta. The new agents have branch offices in New Orleans and Tampa.

# New Equipment Available

## Steel Poles

The Truscon copper bearing "Weltrus" steel poles have been placed on the market by the Truscon Steel Company, Youngstown, Ohio. The pole is composed of two channel leg or chord members formed in one continuous length from special sections of copper-bearing steel. These members are connected at suitable intervals by a continuous lattice web member made from plain or round sections, thus forming a simple Warren truss. The web member is autogenously welded by automatic machinery which accurately regulates the time, current and pressure uniformity of each weld. The manufacturers claim that the "Weltrus" pole is a very economical type which will resist a very large transverse load per pound of pole weight, or per dollar of first cost.

*Portion of channel member and web section of "Weltrus" steel pole*

## Time Switch

A new Sauter time switch with a fourteen-day key-wound clock is being offered by R. W. Cramer & Company, 136 Liberty Street, New York. The clock has a six-jewel lever escapement. Only six full turns of the winding key are needed to wind the spring and the clock is so designed that overwinding is not possible. It is for use on circuits of not more than 15 amp. A cast-aluminum case is used and the case lock can be operated only with the clock-winding key. Every switch undergoes an insulation test of 2,500 volts, although not intended for circuits normally over 250 volts. One type of this switch, the S-15-II-W, can be furnished with a Sunday cut-out.

WELDER TRACTOR COMBINATION.—An improved combination of electric arc welder and Fordson tractor is now offered by the General Electric Company. The principal improvements consist of the substitution of a new type welding equipment and the addition of head and tail lights and a protective cover. This outfit is being marketed direct by the General Electric Company. The older outfits utilized General Electric welding equipment but were not sold by that company.

INDUSTRIAL LIGHTING UNIT.—The "Factrolite" unit, an RLM dome with adjustable features, has been placed on the market by the Bryant Park Electric Lamp Company, 330 West 42d Street, New York. The unit consists of an ivory-enameled aluminum reflector, translucent glass diffuser and adjustable aluminum holder which will permit correct focusing for any lamp from 100 watts to 500 watts. By using a wire holder and a metal or glass diffuser disk the reflector may be suspended in an upside down position for indirect or semi-indirect lighting.

## Arc Welder

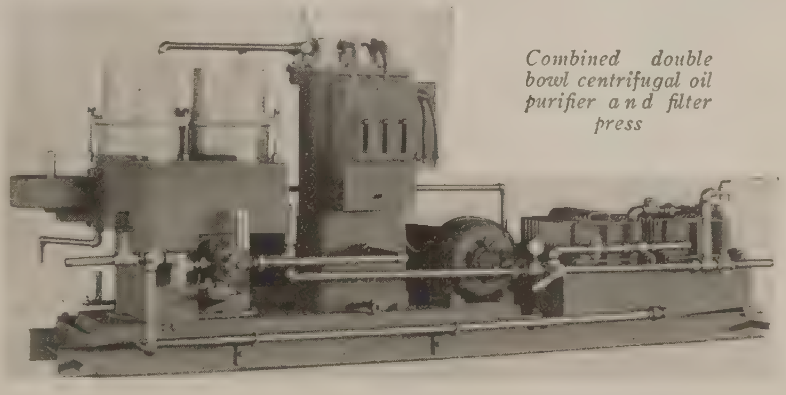
A new 200-amp. single-operator welding set, designed to meet every requirement in both the shop and field, has been developed by the Westinghouse Electric & Manufacturing Company. The set is started by connecting directly across the line. A single rheostat varies the arc current over the entire welding range. Accurate adjustment over the welding range, from 60 amp. to 300 amp., is afforded by steps of 5 amp. The motor-generator and control equipment are assembled in a totally inclosed frame. The exciter, which is overhung from the motor end, is securely fastened to the unit frame. The set can be operated while suspended at any angle that could possibly be required in any application. The motor is wound for 220 or 440 volts and is assembled with the necessary connections made for operation from a three-phase, 60-cycle circuit. If it is desired to operate the unit from a 440-volt, three-phase, 60-cycle circuit it is only necessary to replace the operating coil on the magnetic starter and to reconnect the motor leads.

## Transformer for Post-Top Mounting

A new form of street-lighting transformer especially constructed for mounting on the top of a trolley pole has been designed by the General Electric Company. The new design simplifies the installation problem by eliminating the necessity of drilling the pole for the secondary leads. A support just below the top of the transformer carries insulators to which are dead-ended the street-lighting cable. The primary leads are connected to these, while the secondary leads go through the pole and out into the units through the brackets, thus leaving no exposed wires.

## Oil Purifier

A large-capacity oil purifying machine, the F-100, has been placed on the market by the Hydroil Corporation of Lebanon, Ind. In basic principle the large capacity machine is similar to the smaller Hydroil machine but uses twin bowls, goes through a heater which oil, before it passes into the centrifugal bowls, passes through a heater which raises the temperature to the point at which the impurities are most easily separated out. Twin bowls are employed to keep the diameter of each bowl small, thus giving high centrifugal separation efficiency and the large capacity needed by present-day large power stations. After the oil leaves the bowl, it passes through a pressure settling tank, where all air is separated from the oil. It then passes through a twin filter press. This filter is so designed that one-half of the twin press only is in operation at any one time. All the dirt, water and sludge is removed by centrifugal separation, while the filter press removes the fine particles of carbon that cannot be separated by centrifugal force.



*Combined double bowl centrifugal oil purifier and filter press*

After the oil has passed through the filter press, it can be passed through a continuous test chamber. The test chamber can be so connected with a relay and by-pass valve that only oil of the desired dielectric strength can pass through to the switch tank, transformer or storage tank. The machine is made in stationary and portable models and in combinations to suit any condition.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued March 13, 1928)

1,662,446. Metal Foil Electrode; R. H. Wappler, Yonkers, N. Y. App. filed Jan. 14, 1924. Suitable for use in supplying electric currents to the skin of a patient.

1,662,508. Alternating-Current Motor; S. G. Nottage, Murraysville, Pa. App. filed March 13, 1924. Phase-converting apparatus.

1,662,548. Testing Device; H. R. Van Deventer, New York, N. Y. App. filed Feb. 14, 1924. Which may be used to make tests to discover the nature and location of trouble in electrical circuits as induction coils, lighting circuits, motor or generator armatures, fuses, relays, and various types of wiring.

1,662,549. Method of Speed Regulation for Polyphase Induction Motors; K. von Kando, Budapest, Hungary. App. filed Feb. 28, 1922. By means of changing the pole connections and employing all the coils of the winding in each arrangement.

1,622,555. Universal Bottle Heater; E. Wojciechowski, Aberdeen, Wash. App. filed Dec. 18, 1926.

1,622,556. Thermostatic Control Device; J. C. Woodson, East Pittsburgh, Pa. App. filed June 23, 1926.

1,622,559. Regulator System; J. H. Ashbaugh, Pittsburgh, Pa. App. filed Dec. 4, 1924. Means for extending the range of operation of vibratory regulator systems.

1,622,677. Rotary Relay; C. F. Jenkins, Washington, D. C. App. filed July 21, 1924. For controlling the speed of distant motors, and has for its particular object means for controlling motor speeds by radio.

1,622,697. Time Switch; J. Clifton, J. Robinson and J. Spencer, London, England. App. filed May 5, 1922.

1,622,746. Electric Superheater; E. Howe, San Gabriel, Calif. App. filed Feb. 17, 1927. An electric element for boiling water in boilers for producing steam for steam heating.

1,662,771. Resistance Unit; G. H. Whittingham, Baltimore, Md. App. filed May 8, 1926. Composed of wire coils wound on bodies of refractory material, such as porcelain.

1,662,805. Electrical Stove; H. Frank, Hartford, Conn. App. filed July 23, 1926. Portable type.

(Issued March 20, 1928)

16,908 (reissue). Drink Heater; J. W. Rittman, J. Rood, and W. Driver, Racine, Wis. App. filed July 28, 1923.

16,912 (reissue). Electric Switch; J. D. Hilliard. Schenectady, N. Y. App. filed Feb. 8, 1921. Oil circuit breaker.

1,662,817. Plug for Electric Connections; A. C. Bollmann, St. Louis, Mo., and W. Davies, Granite City, Ill. App. filed Sept. 28, 1922. As electric irons, toasters, etc.

1,662,822. Terminal; M. J. Dunne, West Orange, N. J. App. filed May 2, 1922. For use in welded electrical connections as a rail bond.

1,662,835. Electrical Measuring Instrument; A. R. Rutter, East Pittsburgh, Pa. App. filed March 12, 1926. Watt-meter.

1,662,858. Automatic Control Device for Electric Arc Welding Apparatus; W. R. Hume, Melbourne, Victoria, Australia. App. filed Sept. 21, 1925.

1,662,866. Secondary Battery of Accumulator; E. A. Salazar, Madrid, Spain. App. filed Dec. 14, 1925.

1,662,881. Armature Winding Machine; P. E. Chapman, St. Louis, Mo. App. filed March 22, 1924.

1,662,889. Electric Converter; A. S. Hubbard, New York, N. Y. App. filed Dec. 6, 1922.

1,662,920. Operating Mechanism for Timepieces; N. D. Holbrook, Thomaston, Conn. App. filed Sept. 2, 1926.

1,662,935. Electric Steam Radiator; J. B. Odell, Riverside, Calif. App. filed June 6, 1927.

1,662,970. Safety Device for Electric Lines; C. Grosse, Berlin-Hermsdorf, Germany. App. filed June 12, 1925. Automatic device for domestic service.

1,662,979. Circuit Closer; P. R. Nelson, The United States Army, Fort Totten, N. Y. App. filed May 7, 1927. Granted under the provisions of the Act of March 3, 1883. Used in the operation of submarine mines.

1,662,987. Light Signal; C. S. Snavely, Pittsburgh, Pa. App. filed July 20, 1923.

1,662,988. Train Signal System; E. C. Stafford, Philadelphia, Pa. App. filed March 7, 1921.

1,663,005. Solderless Connecter; L. E. Hendee, Milwaukee, Wis. App. filed June 16, 1924.

1,663,007. Electric Conductor Support; E. H. Jacobs, Chicago, Ill. App. filed Jan. 31, 1919.

1,663,011. Line Conductor Insulator; W. D. Kyle, Milwaukee, Wis. App. filed Sept. 19, 1924. Adapted for attaching conductor wires to buildings.

1,663,013. Battery Terminal; T. P. Logan, Columbus, Ohio. App. filed May 19, 1924.

1,663,030. Cigar Lighter and Advertising Cabinet; C. J. Underwood and J. A. Underwood, Huntington Beach, Calif. App. filed March 16, 1925.

1,663,062. Can Cap Soldering Apparatus; A. E. Roe, Oakland, Calif. App. filed March 28, 1927.

1,663,081. Snap Switch; H. Hertzberg, Brooklyn, N. Y. App. filed April 17, 1926.

1,663,086. Means for Indicating Frequency Changes; M. B. Long, Glen Ridge, N. J. App. filed March 4, 1924.

1,663,113. Electric Soldering Device; S. Clayton, Chicago, Ill. App. filed May 18, 1925. Designed especially for use by jewelers and watch makers.

1,663,137. Electric Spot Welding Machine; R. Mack, Berlin-Tempelhof, Germany. App. filed Feb. 20, 1925.

1,663,138. Switch Operating Mechanism; C. F. Parker, San Francisco, Calif. App. filed Jan. 28, 1924. Interlocked for controlling two circuits as range and water heater circuits.

1,663,153. Pole Supporting Device; A. W. Bensley, Pawtucket, R. I. App. filed Sept. 22, 1927.

1,663,179. Renewable Fuse; F. J. Roth, New York, N. Y. App. filed Sept. 10, 1926.

1,663,187. Multiple Timer; T. J. Barrett, Los Angeles, Calif. App. filed May 20, 1925.

1,663,193. Storage Battery; F. P. Danna, Plaquemine, La. App. filed June 4, 1927.

1,663,200. Resistance Welding Machine; A. Jonsson, Helsingborg, Sweden. App. filed Nov. 10, 1926.

1,663,252. Fuse Holder for Electrical Circuits; M. B. Herbrick, Omaha, Neb. App. filed April 3, 1926.

1,663,255. Electric Pipe Heater; L. P. Hynes, Albany, N. Y. App. filed Nov. 25, 1924.

1,663,258. Electrode Clamp; J. W. Meadowcroft, Philadelphia, Pa. App. filed Jan. 31, 1925.

1,663,264. Lamp Retainer for Lamp Sockets; D. N. Thompson, Syracuse, N. Y. App. filed Sept. 13, 1922.

1,663,318. Electric Machine; T. Schou and R. L. Behrens, Mansfield, Ohio. App. filed June 4, 1923.

1,663,325. Automatic Switch Mechanism; C. H. Wolff, St. Louis, Mo. App. filed Jan. 18, 1926. For opening the circuit of the split-phase winding of a single-phase motor when a suitable speed has been attained.

1,663,333. Fuse; J. H. Carmean, Kansas City, Mo. App. filed Nov. 2, 1925. Adapted to function by absorption of heat from external sources.

---

Information on foreign patents can be obtained through the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

A sole agency is desired in Amsterdam, Netherlands (No. 30,463), for electric advertising novelties.

An agency is desired in Alexandria, Egypt (No. 30,365), for household electrical equipment, domestic appliances and wiring supplies.

---

Any manufacturer desiring to establish agencies abroad may consult with the nearest district office of the Bureau of Foreign and Domestic Commerce, Department of Commerce, where data on available agencies throughout the world are on file.

# New Trade Literature

TIME SWITCHES.—R. W. Cramer & Company, 136 Liberty Street, New York City, has issued bulletin F, in which it describes and illustrates the Sauter type S-15-II electric time switches. Wiring diagrams show the application of the switch to a two wire or three wire system.

SOLDERLESS CONNECTORS.—The Delta-Star Electric Company, 2400 Block Fulton Street, Chicago, Ill., has issued a bulletin covering its rigid stud compression type solderless connectors.

FUSED SWITCH.—The W. N. Matthews Corporation, 3722 Forest Park Boulevard, St. Louis, has issued a price sheet covering the No. 1317 open type Matthews "Fuswitch" with a rating of 100 amp. and 7,500 volts.

STEAM GENERATION.—The Combustion Engineering Corporation, 200 Madison Avenue, New York City, is distributing a booklet entitled "Recent Developments in Steam Generation," presented before the Engineers' Society of Western Pennsylvania of Pittsburgh, Pa., by George T. Ladd, president of the Ladd Water Tube Boiler Company. This booklet summarizes the important developments that have occurred in the field of steam generation during the past decade and discusses present trends.

ELECTRIC RANGE.—"A Complete Summer Sales Plan for the Willwear Walloutlet Electric Range" is the title of a folder prepared by the Beardsley Manufacturing Company, Waterbury, Conn. It contains booklets and pamphlets for distribution and posters for display signs, etc.

ELECTRIC APPARATUS.—The General Electric Company, Schenectady, N. Y., is distributing bulletin GEA-916, describing its electric apparatus such as motor-generators, transformers, synchronous motors, induction regulators and rectifying equipment for use with the Cottrell precipitation process.

ELECTRIC FURNACES.—Bulletin No. 5 issued by the Ajax Electrothermic Corporation, Ajax Park, Trenton, N. J., describes the new Ajax-Northrup motor generator type furnaces and equipment. The principle of operation is illustrated and described.

POLES.—The MacGillis & Gibbs Company, Milwaukee, is distributing an illustrated booklet describing a trip through one of its cedar pole yards at Minnesota Transfer, Minn. A photograph compares the grading prior to 1925 and since that time to show the improving standards of quality now being maintained.

TRAFFIC SIGNALS.—The Crouse-Hinds Company, Syracuse, N. Y., has issued catalog No. 224 covering its electric traffic signals and control equipment. It contains illustrations showing typical installations and also its various types of lamps, cabinets and mountings. Information signs for pedestal and horizontal bracket type signals are also included.

PORTABLE COMPRESSORS.—The Ingersoll-Rand Company, 11 Broadway, New York City, has issued the sixth edition of its booklet entitled "100 and 1 Ways to Save Money with Portable Compressors." It contains comparative cost data on its portable air compressors and air-operated tools. Figures are presented on a man-hour basis so that they can be applied to local conditions. Tables are included to show the number of tools that any given portable compressor will operate. The book is profusely illustrated with applications of portable air compressors and air-operated tools to various jobs.

ELECTRIC FURNACES.—Bulletin No. 4 issued by the Ajax Electrothermic Corporation, Ajax Park, Trenton, N. J., describes and illustrates the Ajax-Northrup furnaces for small production and experimental laboratory work operated from 3-kva., 15-kva. and 35-kva. frequency converters. The use of the furnace and its principles are described and illustrated. The historical development of the company is included and a chart shows the growth in sales from 1917 to the present time.

MOTORS.—Sterling Electric Motors, Inc., Telegraph Road at Atlantic Boulevard, Los Angeles, is distributing a pamphlet describing the Sterling "Cross-Line" electric motors.

FOOD MIXER.—The Reynolds Electric Company, 2650 West Congress Street, Chicago, is distributing bulletin No. 603 covering the 12 quart mixer suitable for commercial as well as domestic purposes.

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for
the Use of All Interested in Analyzing the
Trend of the Electrical Business

## The Trend Toward 115 Volts

WE HAVE heard much, in these recent years, of simplification in manufacture by reducing the excessive number of sizes and styles of certain commodities. In the electrical industry a reduction in the number of different distributing voltages greatly decreases the number of different kinds of lamps required. Complete unification, with one universally adopted value (and the maintaining, in practice, of the actual service voltage at the announced nominal), would result in more uniform operation of appliances, especially heating devices, that now have to perform in some fashion under a variety of conditions.

Complete unification has not yet arrived, but a strong trend toward standardization is evident from a comparison of data on distribution voltages for 1928 with corresponding figures for 1923. These are to be found in the booklet on central-station voltages recently issued by the lamp committee of the National Electric Light Association. Service at 115 volts increased from 38.5 per cent of the total to 58.8 per cent in terms of population served and from 35.6 per cent to 68.2 per cent in terms of number of communities served. Service at 110 volts decreased from 33.6 per cent to 14.8 per cent of the population served, whereas that at 120 volts increased from 11.3 per cent to 20.8 per cent. The drift is therefore distinctly toward standardization at 115 volts, but with a stronger leaning than formerly, or at least a more uniform leaning, toward the next higher voltage step.

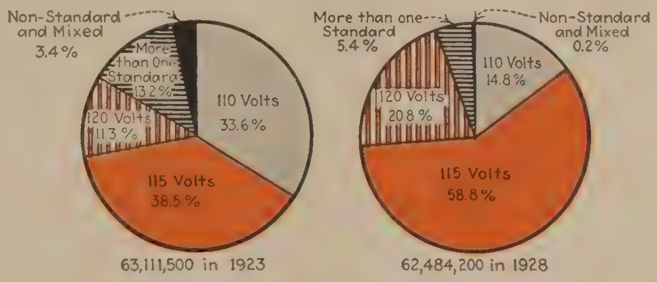
Of equal significance is the reduction in the population served at more than one standard voltage from 13.2 to 5.4 per cent, and the virtual elimination of service at other than the three standard voltages or service at several voltages in the same community.

Even these figures scarcely tell the whole story. Thus, the entire state of New Jersey is served at 115 volts, with the exception of four small communities having either municipal or local private plants, all of which operate at 110 volts.

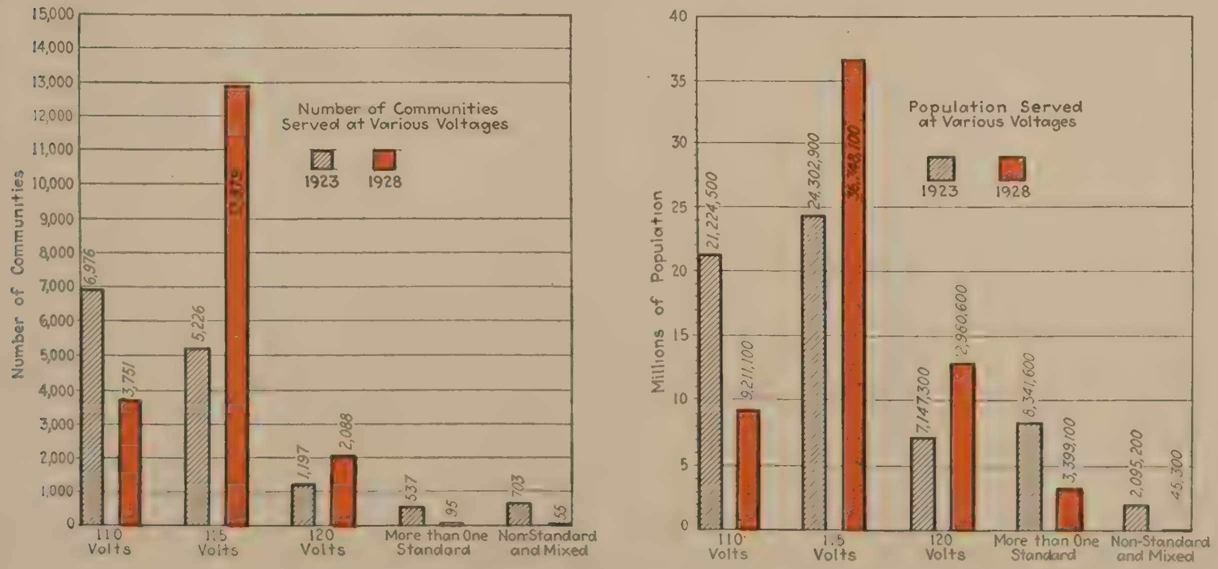
Unification of voltage has apparently been favorably influenced by the consolidation of small operations into larger systems, for with rare exceptions the service voltage in all parts of a given system is the same; in the period of their separate operation that was not necessarily the case.

The number of communities now listed exceeds that in the survey of 1923 by more than 4,000. The actual number of new ones is somewhat greater than that because of the dropping of some on which no information was obtainable. The change is obviously confined to very small communities; the population accounted for is substantially the same as before.

The statement of total population served, 63,111,500, is probably conservative, for three reasons: (a) There has been a very considerable increase in population, particularly in our larger cities, since the 1920 census, on which it is based; (b) it is almost impossible to avoid omitting the population, often considerable, just outside the corporate limits of cities except by estimating; (c) no provision can be made in such a survey for the purely agricultural population represented by the 300,000 to 350,000 farm customers.



Population of Communities on which Analysis is Based and Per Cent of Population Served at Various Voltages



*Service at 115 volts now predominates*

# More Than Seasonal Gain in Middle Atlantic States Industrial Activity

MANUFACTURING plants in the Middle Atlantic States witnessed a slightly more than normal seasonal increase in activities during February, and the productive activities of these plants were also about 12.5 per cent over those of February, 1927. It appears that industrial conditions in this section during February were slightly better than those characterizing industry in the nation as a whole.

During February five of the section's primary industries—chemicals and allied products, ferrous and non-ferrous metal working plants, rolling mills and steel plants, paper and pulp, and textiles—witnessed productive activities materially over those reported for February, 1927. On the other hand, both the leather and its products industry and the paper and pulp industry were operating slightly below February, 1927. It now seems probable that the volume of industrial production during the first quarter of the current year was between 7 and 10 per cent over that reported for the same period last year.

*Indexes of Productive Activity in the Middle Atlantic States*

All Figures Adjusted for Number of Working Days

| | Feb., 1928 | Jan., 1928 | Dec., 1927 | Average Full Year, 1927 |
|---|---|---|---|---|
| All industries | 126.6 | 116.2 | 109.9 | 107.5 |
| Chemical and allied products | 134.0 | 129.0 | 107.3 | 108.4 |
| Food and kindred products | 103.0 | 93.0 | 97.0 | ..... |
| Leather and its products | 122.0 | 119.0 | 115.0 | 101.9 |
| Lumber and its products | 114.0 | 102.6 | 104.5 | ..... |
| Metals group | 122.6 | 112.4 | 101.4 | 107.7 |
| Rolling mills and steel plants | 120.8 | 110.5 | 101.5 | ..... |
| Metal fabricating plants (ferrous and non-ferrous) | 124.4 | 114.4 | 101.4 | 105.6 |
| Paper and pulp | 118.7 | 113.4 | 123.5 | 122.6 |
| Stone, clay and glass | 116.9 | 103.9 | 97.6 | |
| Textiles | 130.2 | 119.8 | 120.0 | 108.4 |

## *Well-Earned Success of the Southwestern Division*

IN MANY respects the Southwestern Geographic Division of the National Electric Light Association may well serve as a model for other sections. Its committees are active, concern themselves with the everyday intimate problems of the region, and their work so commends itself to the executives of the public utility companies that they give the division their whole-hearted support. There is now apparent a wonderful spirit and cohesion in the public utility field in the five states constituting the Southwestern Geographic Division, brought out into bold relief no doubt by the problems and circumstances of the devastating flood which last year swept over Arkansas, Mississippi and Louisiana. There is also apparent a great faith in the ultimate development of territory not particularly blessed with natural resources but possessing latent fertility and desirable climate.

It is an inspiration to electric light and power men from other sections to witness the rapid extension of circuits into virgin territory all through this region. Nothing could more clearly prove the confidence which public utility operators have in the ultimate development of local resources than the utility companies' own great investment. It is this spirit—the spirit in which empires are built—that accounts for the remarkable progress recorded last year in the Southwest. The same determination to will and to do was plainly manifest in the convention of the division at Edgewater Park, Miss., last week. Association work which enables companies engaged in it to show a growth three to four times greater than the normal for the whole country certainly merits executive support. Not that association work of itself will perform miracles, but because it inspires effort and equips those eager to work with the necessary facts and imbues them with the enthusiasm to accomplish results. The results achieved by the Southwestern Division speak eloquently of hard work delighted in.

## *Creating a Permanent Money Market*

ONE of the nation's largest operating power and light companies states in its annual report that the cumulative effect of selling stock to customers continuously over the past ten years was manifest in facilitating the sale and distribution of its securities during 1927. Junior financing carried on in this way, the report shows, totaled more than $30,000,000.

At a time when the proportion of financing carried on through direct sale to customers is declining—it dropped from 23 per cent in 1925 to 19 per cent in 1926 and to 11 per cent last year—it may be worthy of consideration that, for one company at least, customer sales have had a value beyond merely the raising of a specific amount of money in any one year and the improvement of public relations. The policy persisted in has developed what may be regarded as a permanent money market for junior financing. The company in question has combined customer sales with the issue of rights. The existing number of its shareholders is exceedingly large, and all of these are readily available potential buyers of future issues. Furthermore, the policy has reduced selling costs radically. An official of the company stated to the ELECTRICAL WORLD recently that "the cost of selling securities through our customer ownership campaign is, on the average over a ten-year period, about 60 per cent cheaper than the cost would have been for other modes of financing. The figures for cost are used in the underwriting sense and do not take into account the yield on the types of securities in question, which would enter into a computation of real cost of money to the company."

In the present easy money market it would be an error to overlook the advantages of customer sales in junior financing.

## *New Order in Production*

AGITATION to amend anti-trust laws is acute because production is ahead of consumption and because restrictive legislation has made industrial prosperity rest upon ability to reduce costs and not upon selling prices. It is argued that industrial law should be based upon the economic requirements of the country and that these requirements indicate a monopoly in many industries, with public control of unreasonable profits. It is said that the time has arrived to make industrial law harmonize with economic life.

Industry is moving toward a new order in this country, and electricity has had a decided influence on the new form industry is taking. The enormous plant in one location has been found uneconomical and is giving way to the use of multiple production plants located in local marketing areas or where labor, raw materials and taxes give advantages. There has been found an economic limit to size in an industrial plant, and as a consequence of this fact industry is decentralizing its production. The cement, gypsum, steel and textile industries are building plants in many territories, and the size of these plants is dictated by minimum production cost figures. These multiple plants are then tied into a national executive and sales organization which affords each plant the best executive and sales talent. These industries have found this method best to meet present economic conditions.

Electric utilities should back this decentralized industrial plant movement and should study carefully proposed industrial legislation. Decentralization is made possible largely because electric power is available alike in large and small communities, and the utilities can help national conditions and themselves by taking power to any locality where raw material and workers demand it. All elements in a community benefit from industrial decentralization, and much better social and economic conditions are created.

Carried to its logical conclusion, however, decentralized industry means the creation of monopolies to insure the fullest economic benefit to both capital and labor, and serious thought should be given to legislation so that this type of industrial progress may be directed along lines which make for public wellbeing.

* * * *

## *Service and Its Definition*

UTILITIES, more than almost any other industry, labor under the banner of service. The word has been vastly misused, but, as applied to electric light and power companies, it involves the supplying of electrical energy when, where and in such manner as the customer may desire it. It means the supply of uninterrupted, steady potential energy at prices commensurate with a fair return to the security owners of the utility. It involves an obligation to technical and economic progress. Grand gestures, endless words, devout protestations of altrusim, full-page self-eulogies in the newspapers or blatant electric signs are not proof of service. The word does not involve, necessarily, the repetitive annoyance of high-pressure appliance and stock salesmen at the customer's front door, nor does it include undue corporate activity in politics. Service is fundamentally the only thing that a utility has to sell—good service—more service—better service.

* * * *

## *A Convention Echo*

IN THE non-technical world it is freely accepted that engineering is a romantically absorbing phase of modern life. The glorious accomplishment of the seemingly impossible and the spectacular element in successive triumphs leave the lay mind in bewildered appreciation. There is, however, in this same non-technical world a definite impression that engineers, as individuals, are tremendous bores. Possibly it is because as a class they tend to do much and say comparatively little. When a technical meeting is over and the last listless word has been said the listener may well wonder if this reputed dullness of the engineer is not a very real characteristic, for inflectionless voices, muffled murmurings and the reading of quivering pages, interrupted only by furtive glances at the audience, are the rule rather than the exception. That the subject matter is theoretical, or involved, or specialized, or a part of one's every-day life, does not bar it from an interesting, or at least interested, presentation. It is said that one of the great actors of yesterday could, and did upon several occasions, recite the alphabet or multiplication table with true emotional values.

The speakers at the last annual meeting of the American Society of Mechanical Engineers were parties to an interesting experiment. A professional public-speaking coach was engaged by the meetings and program committee, and with the co-operation of a number of those who were to present papers a courageous and unusual effort was made to ameliorate the potential sufferings of the audience. This is something which should gain merit through repetition. There is one obligation that every one who speaks or writes should unfalteringly meet, and that is—to be interesting. It is not incompatible with accuracy, brevity or ability.

## *Stars in the Meadow*

THERE is, in all probability, a special, inconspicuous corner of Heaven reserved for artists—for those who work for the sheer ecstasy of creative effort. There is also, be assured, a reward for the workman who handles fine machinery with the spirit of an acolyte.

To enter a generating station in which the proportions of roof and walls have been balanced and molded with a fine sense of artistry and in which machines have been placed and designed for esthetic satisfaction is as refreshing as a cool, grass-fragrant breeze in a foundry. To see paint and metal gleaming brilliantly, to find pastel shades instead of hard reds, greens, blacks and browns, to see transformers and circuit breakers without an accompanying trace of telltale drops of oil on a spotless floor, to discover illuminating values and fixtures of perfection, to find unconstricted space around all apparatus, and to meet operating men with a simple, unboasting faith that theirs is the finest station in all the world and that they are privileged to have the task of keeping it in superlatively gleaming glory is—well, unusual.

* * * *

## *High-Voltage Cable Problems*

HIGH-VOLTAGE underground cables, when subjected to wide variations of load, pass through a temperature cycle which has long been recognized as one of the sources of trouble in this type of cable. With elevations of temperature the insulation expands, stretches the lead sheath, which is not elastic, and does not return to its original dimensions when the cable cools. The result is the formation of voids in which gaseous ionization takes place, resulting in alterations in power-factor characteristics and progressive deterioration of the insulation. Particular emphasis was drawn to this serious problem not long since in the paper at the Chicago regional meeting of the A.I.E.E. by L. Emanueli, describing the 132-kv. cables now in operation in New York and Chicago. The careful provision which has been made in these cables for meeting the trouble referred to is undoubtedly one of the most important elements contributing to the successful experience so far enjoyed by these record-making installations.

Oil-duct cables of the 132-kv. type, however, involve elaborate auxiliary equipment in the way of reservoirs, pressure tanks, junction boxes and the like, and it is not as yet evident that these auxiliaries are always justified for cables of moderate voltages. The danger arising from excess-temperature cycles in these cables must therefore be met in other ways. The paper of T. N. Riley in the ELECTRICAL WORLD of Jan. 21 is an interesting discussion of this phase of the general problem. It is a plea for conservative design and for a more careful scrutiny than is usual of the electric performance of cables after installation. In fact, he advocates the study of the changes in the power-factor-voltage relation following the extreme temperature cycles which may occur. The presence of dangerous voids manifest itself very quickly in a change in the shape of the power-factor-voltage curve. In particular, Mr. Riley shows that it is possible so to construct a cable that any voids that are created by a temperature cycle will occur in regions not subjected to electric stress, as, for example, in the filling of a three-phase cable in which the separate conductors have metallized wrappings. The curves indicate that a cable of this type may show an excellent power-factor performance which is well preserved after a temperature cycle corresponding to the extreme rating of the cable.

Another feature of interest in Mr. Riley's paper is his discussion of the properties of cable paper and of the impregnating oil separately. Particularly in connection with the oil, elevation of temperature is seen here also to play a very important rôle. It is evident that cable oils are anything but stable materials, and if a moderate temperature cycle can bring about great increases in power factor, it is altogether probable that continued application of electric stress causes various changes which may seriously affect not only the power factor but also the life of the cable. There is too little information available on the properties of oils, and the problems associated with them offer a fine opportunity for experimental investigation.

* * * *

## *Abolish the "Gypper"*

LET any business show signs of prosperity and it attracts a horde of parasites whose existence depends upon their ability to capitalize upon and at the same time undermine the good name and reputation which that business has built up through honest service and costly development. In the electrical industry there is a particularly virulent and obnoxious type of this parasite—the "gyp." It might not be so bad if there were but one of the species, but the "gyp" comes with variations. There are "gyp" dealers, "gyp" jobbers, "gyp" appliances, "gyp" radios, "gyp" parts, "gyp" wiring supplies, "gyp" manufacturers and gyppers who gyp for the sake of gypping. The business methods—there are no ethics—of the gyp and of gypping are familiar to every responsible man in the electrical industry. The dictionary defines a "gyp (*slang, U. S.*)" as a "swindler," which rightly puts him in the same category with the goldbrick artist or the operator of three-card monte. It's the old army game.

The sale of inferior electrical equipment has already been permitted to go too far. There have been too many sub-standard devices foisted upon the public. Not only does the sale of such products lessen the sale of reliable electrical devices made by reputable manufacturers, but, if allowed to continue, it will seriously jeopardize the fair name of the electrical industry. Fortunately, in some localities it has been possible to curb the selling of sub-standard devices by passing local city ordinances which make it a misdemeanor for any merchant to sell any electrical appliance or other equipment which does not meet the requirements of the city electrical department. Where such an ordinance is in effect customers are protected against the hazard of shoddily made and dangerous merchandise. The operations of the unscrupulous dealer are thus measurably circumscribed. But this is not enough. Responsible electrical manufacturers owe it to themselves and to the electrical industry to educate the public to the value of buying reliable electrical apparatus. That the public should have to learn through experience that sub-standard merchandise is dear at any price is too costly a process to the customer and is costing the electrical industry too much in lost business and lost prestige. There should be concerted action by electrical manufacturers, reliable dealers and the central-station industry which would effectively abolish the gypper. He has no legitimate place in developing the electrical industry.

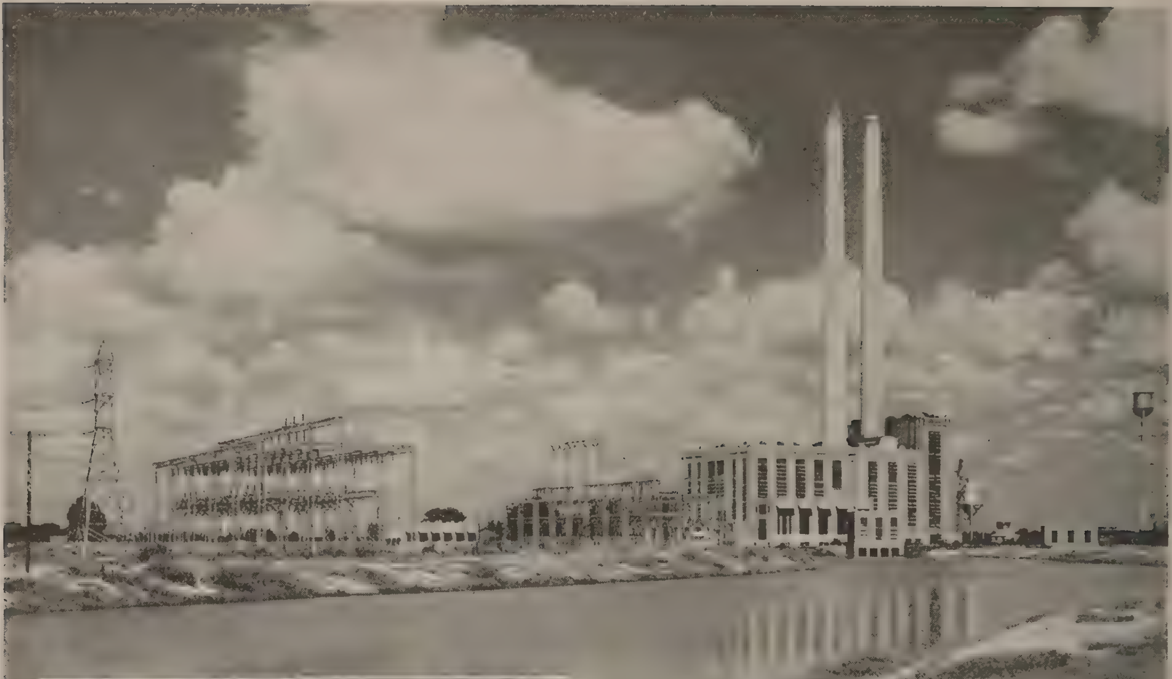
## *Making Team Play Count in Power Sales*

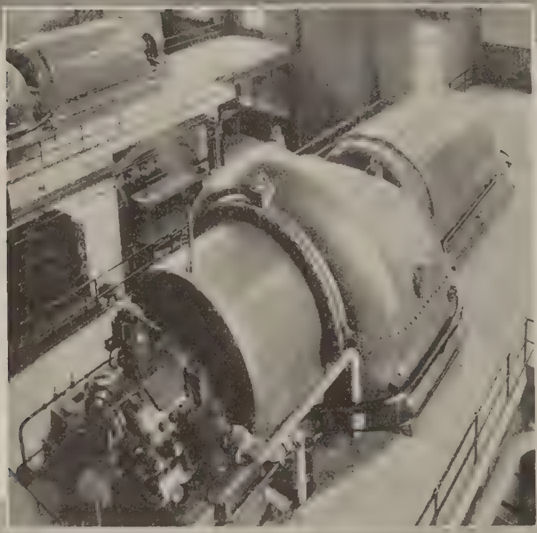
TRANSFERS of light and power company administration from individual to centralized management call for no little open-mindedness on the part of both local and headquarters executives during the readjustment period which is inevitable with such changes. Among the important problems which often have to be solved at such times is the establishment of effective team play between local power sales engineers and those of the headquarters office, assuming the customary set-up of specialists at the central point of group administration and local properties of sufficient strength to maintain one or more trained industrial men each. Failure to define the responsibilities of sales engineers at each end of the line and to provide for authoritative direction of all industrial service activities only prolongs the readjustment period, retards market development and at times, indeed, leads to actual loss of highly competitive power business.

Self-forgetful team play is the key to such situations, coupled with clear definitions of responsibility and authority. Local sales engineers are in a position to a man to render invaluable service in power business solicitation in co-operation with headquarters forces. Their residence in the territory, local acquaintances and friendships in industry, knowledge of the local system and its operating practices are the result in many cases of years of faithful work and good citizenship. These men have much to bring to the counsels of the larger organization, but if they are debarred from whole-hearted team play, whether by inability to adapt themselves to the new order, fear of diminished usefulness through sharing responsibilities and credit with "H. Q." staff members, or through the slowness of their immediate superiors to appreciate the value of specialized headquarters service in terms of recurrent annual revenue representing perhaps ten or fifteen times its initial cost, something must indeed be wrong!

On the other hand, the headquarters sales engineering staff must maintain a receptive attitude toward local ideas if the best results are to be obtained. Anything remotely resembling a "high-hat" approach to the territorial sales engineer or his customers is a colossal blunder. Team play demands many things, but among the vital requirements nothing surpasses a sympathetic and continuous desire to serve the local property's needs to the utmost ability of the entire staff. There is no room for either individual or departmental jealousies to enter into these relations.

No matter how much authority may be lodged with headquarters vice-presidents or what may be their titles, no matter how freely headquarters sales engineers may enter into negotiations with local customers or call upon them (naturally informing resident salesmen of their activities and seeking their co-operation whenever possible), it is fundamental to success that all concerned pool their abilities and their efforts for the good of the service. Absurd and indefensible practices and prohibitions often arise during the transition period between individual and centralized management, but with clear vision and a determination to work out a co-operative program for business development unhampered by nonreceptiveness to new ideas and improved methods, with a disposition and a clean field to practice teamwork: what may not be achieved!





## *Lignite Burned in New Trinidad Station*

TRINIDAD station from across the intake canal. The 132-kv. switching structure is on the left and the 60-kv. structure is in the center of the above view. The control house is in between. The operators' village as seen from station roof, with artificial cooling lake in background, is shown in the lower illustration. Water-treating plant, transformer-cooling waterspray pond, ash-disposal track and discharge canal in foreground.

# Trinidad Burns Lignite

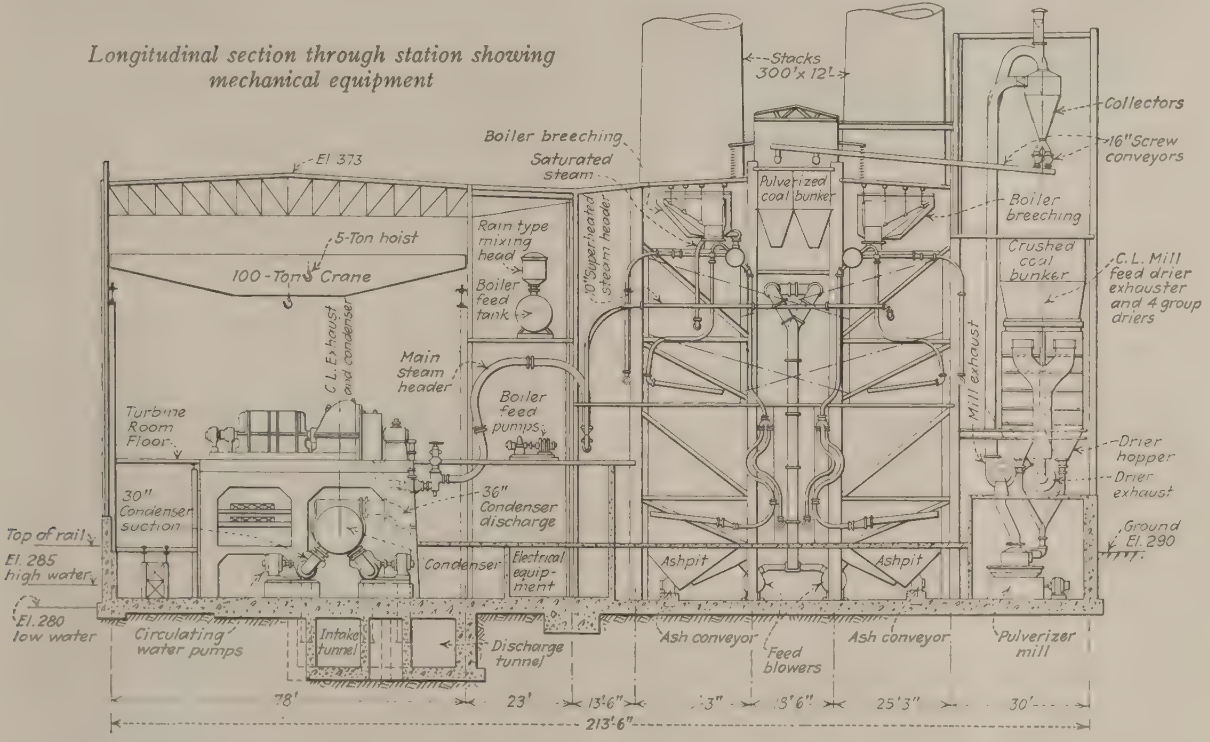
### Base-load plant of Texas Power & Light Company in operation. Details of construction and equipment. Pulverized lignite proves economical

By E. T. Keck

*Superintendent of Power Texas Power & Light Company*

ALTHOUGH the Trinidad station of the Texas Power & Light Company has been in operation only a short time, the developments leading to its erection may be traced back over a period of ten years. The territory served by the Texas Power & Light Company and interconnected companies is characterized by widely separated towns and cities and low density of rural population. The 2,400 miles of transmission line making up the company's transmission system extends 290 miles from north to south, 260 miles from east to west and is a part of an interconnected system extending over 500 miles from east to west and about 400 miles from north to south, all within the state. Consequently, the selection of a station site involved careful study to determine the probable future load center so that the station might be developed to its economical capacity without involving too great a transmission problem. At the same time it was necessary to select a location with due consideration to availability of water and fuel. After investigation of the fuel resources, it was decided to locate the new station in Henderson County near the Trinity River and within 10 miles of an area containing an adequate quantity of lignite.

As the flow of the Trinity River varies from 20 sec.-ft. to 75,000 sec.-ft. (the period of minimum flow generally occurring at the time of the system peak load) it was necessary to create an artificial cooling lake to which water would be supplied by pumping from the river.



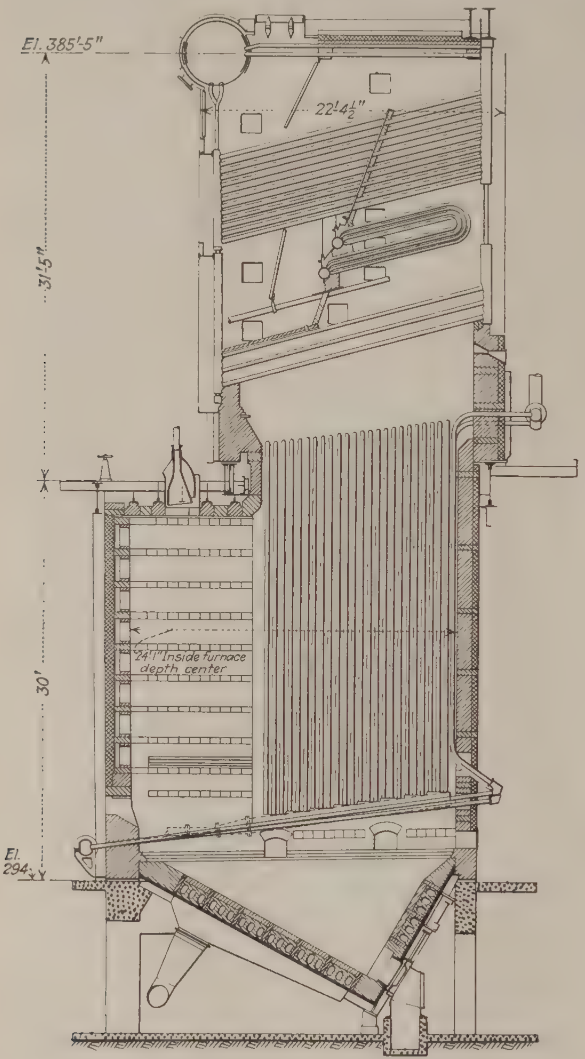
*Longitudinal section through station showing mechanical equipment*

The site chosen for the plant is on the east side of the Trinity River about 1½ miles south of the village of Trinidad and 65 miles southeast of Dallas.

It is, roughly, a rectangular plot with an area of 1,600 acres, on which are located the circulating water lake, employees' village, outdoor switchyard, control house, lignite storage yard, lignite storage tracks, storehouse, laboratory, water-treating plant and main station building. The circulating water lake covers 650 acres of this area. The buildings, switchyard, lignite storage yard and tracks are located northwest of the lake, adjacent to a natural slough which is used as a discharge canal to the east end of the lake.

Trinidad is a base-load station, but the extent of the system necessitates the division of load with several other stations for voltage regulation and prohibits carrying the entire load on the most economical plants at times of light system load.

Reliability and continuity of fuel supply are assured by the proximity of the mines, and while a large proportion of the fuel burned will be supplied from shaft mines, deposits of lignite, sufficient for six months' supply, are stripped in advance so that fuel may be delivered to the station by only a shovel and train crew. In addition, a month's fuel supply is kept in storage at the plant for emergency purposes to insure against failure of delivery from the mines.



*Sectional elevation of boiler and furnace*

All station auxiliaries, with the exception of one turbine-driven boiler feed pump and the steam jet air pumps, are driven by full-voltage-starting induction motors, which may be supplied with power from either of the main generators, the 60-kv. bus or the house turbo-generator, which is designed to pick up load at 3 per cent drop in frequency. Three-stage bleeding of the turbines for feed water heating, the use of a gland seal leak-off condenser and low-pressure drip returns provide for economical feed water heating and low make-up. The absence of preheaters or economizers and the use of natural draft contribute to simplicity of operation.

### BUILDING CONSTRUCTION

The station buildings are of red brick with gray terra cotta trim on structural steel resting on a monolithic concrete slab which is supported by nineteen concrete caissons, 16 and 23 ft. in diameter, extending 40 ft. below the ground level to rock. The main building, containing the turbine room, boiler room and fuel preparation bay, is 213 ft. long east and west and 100 ft. north and south, with a two-story office and machine shop 100x30 ft. adjoining on the south side of the turbine room. The crusher house is 23x30x86 ft. high above the ground level, located 28 ft. east of the main building and connected with it near the top by an inclined conveyor bridge. The laboratory and water-treating plant and the intake house are in separate buildings south of the main building and the storehouse is a corrugated iron structure located northwest of the station building. The control house and switchyard are west of the main building. The capacity of the present installation is 40,000 kw. in two 20,000-kw. units, but the cooling water system, railroad tracks and control house are designed for an ultimate capacity of 160,000 kw. and the lignite crusher house is equipped for twice the present capacity. The present main building will accommodate only the two turbo-generators and four boilers now installed and the lignite pulverizing and drying equipment is sufficient for only the present capacity. The north side of the building is temporary and is covered with corrugated asbestos sheeting painted brick red to harmonize with the permanent walls.

### FUEL- AND ASH-HANDLING SYSTEM

The following is a typical analysis of the Texas lignite as received at Trinidad: Moisture, 33.73 per cent; volatile matter, 21.10 per cent; fixed carbon, 35.93 per cent; ash, 9.12 per cent; sulphur, 0.48 per cent; B.t.u. per pound, 7,000.

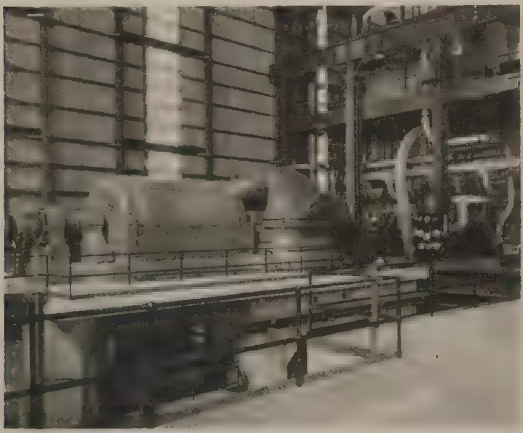
Before the combustion equipment for this station was selected tests were made with this fuel on stokers and in a plant equipped for burning pulverized bituminous coal. The pulverized fuel system was selected in preference to stokers after comparing the relative economy and fixed charges.

Lignite is delivered by the mining company to the storage tracks in 50-ton bottom dump cars. Switching in the plant yard is done by a 25-ton storage-battery locomotive and an electric car puller is provided at the crusher house for emergency use. The lignite is weighed on track scales, dumped into a track hopper at the crusher house and is carried from the track hopper into the crushers by 30-in. apron feeders having 24-in. diameter magnetic pulleys on the head shafts for the removal of tramp iron. The crushers are single roll machines arranged two in series with vibrating screens between the primary and secondary elements. The crushed lignite is then elevated to the top of the crusher house, whence it is carried by belt conveyors over weightometers through the connecting bridge into the main building, or diverted into the storage yard through a chute in the east wall of the crusher house. As the storage is permanent the normal route is into the fuel preparation bay, where it is discharged over another set of magnetic pulleys onto cross conveyors, whence it is dumped into the crushed lignite bunkers. A dust-collecting system removes dust from the points where the crushed lignite falls on the belt conveyors in the crusher house and on the cross conveyors over the crushed lignite bunkers in the preparation bay.

The driers, located directly under these bunkers, are of the steam grid type, supplied with steam at 10-lb. gage pressure bled from the seventh stage of the turbines, or, if necessary, taken directly from the saturated steam header through reducing valves. The pulverizing mills are at basement floor level, each directly under its drier. The mill exhauster fans and drier fans are on a floor between the mills and driers. The pulverized lignite is drawn from the mills by exhauster fans and discharged into cyclone separators above the screw conveyors on the top floor of the pulverizing bay.

The mill exhauster system operates in a closed circuit and under a slight vacuum, maintained by a cross-connection to the suction of the drier air-circulating fan, which tends to eliminate dust discharge from this equipment. The drier circulating fans discharge through cyclone separators and combination steam and water jet air washers. The drier cyclones are adjusted to produce a slight vacuum at their base and discharge any collected dust into the screw conveyors. The vacuum in the cyclones creates a slight vacuum in the screw conveyors and pulverized fuel bunkers which eliminates dust from these sources, and also keeps moist air out of the pulverized fuel bunkers, where the moisture would condense and cause caking of the lignite. Screw conveyors transport pulverized lignite from the discharge of the cyclones to storage bunkers in the aisle above and between boilers.

The entire fuel conveyor system from the crushers to the pulverized fuel bunkers is in duplicate. The crushers, bucket elevators and belt conveyors are electrically interlocked, as are also the three sets of screw conveyors which carry the pulverized fuel, so that they can be started only in the proper sequence.

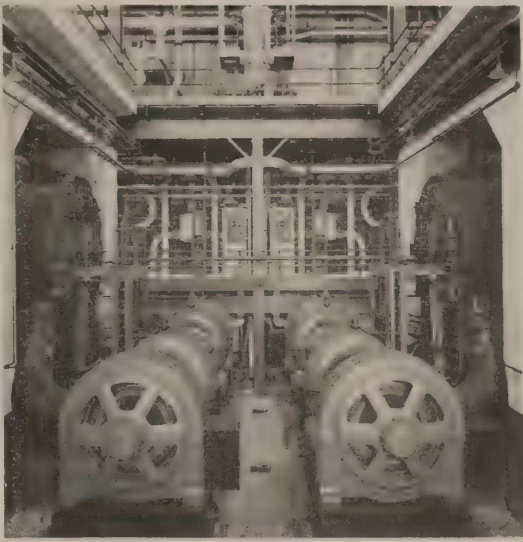


*Turbine room from southwest corner*

Two 20,000-kw. units at right and center and 1,200-kw. house generator at left next to temporary wall. Note neat arrangement of boiler feed pump piping in opposite corner and boiler feed tank on deck above.

The pulverized lignite is drawn from the bunkers by helical feeders and blown vertically downward into the furnaces through fantail burners by primary air drawn from around the ashpits by the primary air fans. Steam jets are provided in each burner for use in case of primary air failure. Each boiler is served by twelve burners and feeders arranged in groups of six, independently driven and controlled. The feeder screws are driven by constant-speed motors through variable-speed transmissions.

The ashpit floors slope toward the rear of the furnaces, from where the ashes are drawn into water-sealed drag scraper conveyors which carry them to a cross-conveyor at the south side of the building. The cross-conveyor is elevated at the east end and discharges into a skip hoist which elevates to a bunker, whence the ashes are dropped into dump cars and transported to low ground south of the station.



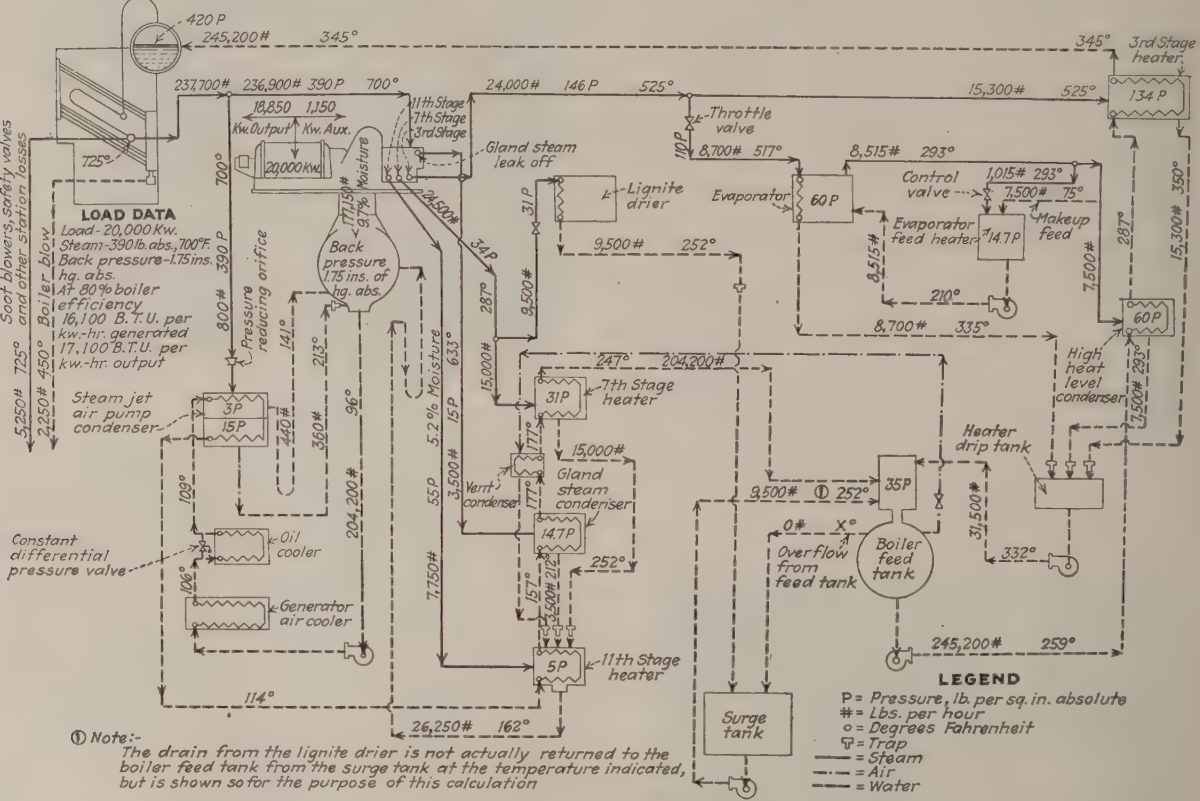
*Condenser pit showing evaporator and heater gallery in background*

When lignite was first placed in storage spontaneous combustion developed along the slopes of the pile, particularly on the windward side and where the lignite was not properly packed. To eliminate this earth dikes were built around three sides of the storage area and the lignite spread in 2-ft. layers, leveled and packed with tractor and roller. This has eliminated all serious heating and spontaneous combustion in the 18,000 tons in the storage yard.

### STEAM-GENERATING EQUIPMENT

The boiler house occupies the center section of the main building between the fuel preparation bay and the turbine room. The present installation consists of four boilers, arranged two on each side of the firing aisle, which will extend the full length of the ultimate installation. The boilers are 18,756 sq.ft. Babcock & Wilcox cross-drum, sectional header type, with interdeck superheaters designed for steam pressure of 425-lb. gage and temperature at the superheater outlet of 750 deg. F. Normal operating conditions are 400-lb. gage pressure and 735 deg. F. total temperature. The boilers are standard in every respect except the lower section of tubes, from which alternate rows are omitted to eliminate staggering and to provide more room between tubes, thereby reducing tendency for ashes to bridge. Boiler tubes are 4-in. No. 6 gage with the exception of the two lower rows, which are 3¼-in. No. 8 gage. The superheaters, located between the upper and lower tube decks, contain 4,000 sq.ft. of surface, arranged in four loops with three steam passes. Sixty-six tubes, or a possible area of 700 sq.ft., are blanked off in the inner loop.

A 10-in. steam lead runs from the non-return valve on each boiler to a 16-in. manifold located on the west, or turbine room side, of each pair of boilers and on the center lines of the main turbines. These manifolds are connected by a 12-in. vertical expansion loop, and as extensions are made additional manifolds will be similarly located and connected by expansion loops to form a continuous header. Steam leads to the main units are 14-in. vertical expansion loops leading from the center of the manifolds over the auxiliary bay and passing through the turbine room operating floor just ahead of the main throttle valve. The 6-in. steam lead to the house turbine and 3-in. lead to the boiler feed pump turbine are connected to the expansion loop between manifolds near the manifold for No. 2 turbine. Valves at the manifolds on steam leads from the boilers, steam leads to main turbines and those at each end of the loop connecting the manifolds are motor-operated, controlled by nearby push-button stations, but they may be closed from an emergency control panel in the plant superintendent's office. The valves on the leads to the house turbine and boiler feed pump turbine and non-return valves on the boilers are all hand-operated. The saturated steam header is a 4-in. line located directly above the boiler drums, connected by a straight line at the south end and by an expansion bend at the north end, forming a continuous loop. Horizontal expansion bends are located on each side of the loop between boilers.



**LOAD DATA**
Load-20,000 Kw.
Steam-390 lb. abs., 700°F.
Back pressure-1.75 ins. hg. abs.
At 80% boiler efficiency
16,100 B.T.U. per kw.-hr. generated
17,100 B.T.U. per kw.-hr. output

① Note:-
The drain from the lignite drier is not actually returned to the boiler feed tank from the surge tank at the temperature indicated, but is shown so for the purpose of this calculation

**LEGEND**
P = Pressure, lb. per sq. in. absolute
# = Lbs. per hour
° = Degrees Fahrenheit
Ɏ = Trap
—— = Steam
—·— = Air
– – – = Water

*Full-load heat-balance diagram*

Three motor-driven and one turbine-driven boiler feed pumps are provided, any two of which will feed the boilers under maximum station load conditions. The turbine-driven pump, which is for emergency use only, is controlled by a 3-in. pressure governor. The motor-driven pumps are driven by constant speed induction motors. Boiler feed is controlled by two Copes regulators per boiler and a constant excess pressure is maintained by an S.-C. differential pressure regulating valve installed ahead of each Copes valve.

The feed-water heating system is designed to operate on the regenerative cycle, using steam bled from the third, seventh and eleventh stages of the main turbines. The condensate passes successively through the generator air cooler, turbine oil cooler, steam jet air pump condenser, eleventh stage heater, gland steam condenser, boiler feed tank vent condenser and seventh stage heater into the boiler feed tank through a rain type mixing head. Proper level in the boiler feed tank is maintained by overflow to surge tanks in an underground room adjacent to the stations and by float control of pumps which supply water from surge tanks to feed tank. Duplicate headers lead from the boiler feed tank to the pumps. Feed from the pumps to the boilers is normally through the high-heat level condensers and third-stage heaters to the 8-in. boiler feed loop header. However, an auxiliary line is provided through which the pumps may discharge directly into the loop header.

Boiler feed make-up is supplied by single-effect evaporators which use steam bled from the third stage of the main units. The evaporator feed is lake water which has been settled, filtered in pressure sand filters and treated in Zeolite softeners. Well water from the domestic supply may be treated and used in the same way, or, if necessary, fed directly into the boiler feed tank without treatment.

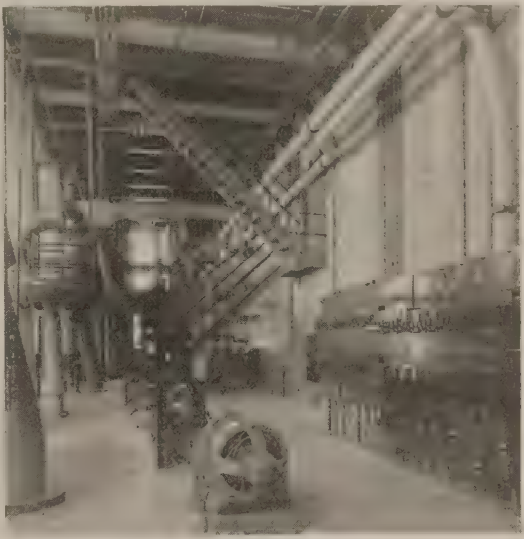
The boilers are fired from the rear or drum end through flat arches. The back and a portion of the furnace side walls adjacent to the arch are of brick cooled by the secondary air which passes through openings in the outer wall into horizontal ducts, from which it is distributed through sinuous ports in the rear furnace wall which are so designed as to protect the steel work in the outer wall from radiant heat. The other walls are water cooled with 24 fin tubes in each side wall and 26 plain tubes in the front wall opposite the burners. The slag screen over the ashpit also consists of 26 plain water tubes. The wall and screen tubes are all connected by external headers to the boiler circulation, their 2,520 sq.ft. of heating surface giving each boiler a total heating surface of 21,276 sq.ft. Each pair of boilers is served by a reinforced-concrete stack 300 ft. high above the boiler room roof, 12 ft. inside diameter at the top and supported by the building steel. Each furnace is approximately 25 ft. square inside below the arch and 35 ft. high from the slag screen to the lower boiler tubes. The ashpit, with 30 deg. and 60 deg. sloping sides, has a maximum depth below the slag screen of 12 ft. The furnace volume above the ashpit is 18,540 cu.ft., which gives a combustion chamber volume of 0.988 cu.ft. per square foot of boiler surface and 0.871 cu.ft. per square foot of heating surface, including the surface in the water-cooled walls and slag screen.

### MANUAL CONTROL

The combustion control is manual. Each individual boiler control panel is equipped with boiler pressure gage, multipointer gage showing furnace draft, top first pass draft, uptake draft and primary air pressure; boiler meter equipped with indicating, recording and integrating steam flow elements and air flow, flue gas temperature and steam temperature recording elements; speed indicators and speed-controlling switches for the feeder drives and indicating lamps and stop buttons for feeder motors and primary air fan. On the master boiler room control board are mounted a clock, boiler blow-off temperature recorder, boiler feed temperature and pressure recorder, boiler feed tank low water alarm, surge tank high water alarm, multipointer stack draft gage, boiler feed pump indicating lamps and stop buttons. The individual gage boards are located next to the cross aisle between the boilers leading to the turbine room and fuel preparation bay. The master gage board is located at the intersection of this aisle and the firing aisle and facing in the direction of future extension.

*Auxiliary switch room*

A master pilot gage and a station load indicator are mounted at the south end of the firing aisle. The uptake damper, primary air damper and secondary air damper for each boiler are controlled by hand wheels located near the individual boiler control boards. Thus all firing controls are located on or adjacent to the boiler control panel so that the fireman can watch all instruments while making firing adjustments.



*Turbine room auxiliary bay*

Steam lead to No. 1 turbine, auxiliary exciters and auxiliary load centers in foreground and boiler feed pump piping and steam lead to unit No. 2 in rear.

### TURBINES AND TURBINE AUXILIARIES

The turbine room occupies the west section of the building and is separated from the boiler room by the auxiliary bay. The turbo-generators are placed with their axes east and west or perpendicular to the length of the ultimate turbine room so that the steam end is as near as possible to the boiler room and the generator close to the transformer structure. The main units are set on individual decks 20 ft. above the ground and 30 ft. above the condenser pit floor. The house turbo-generator is located north of the present main units. A railroad track runs across the west side of the turbine room to the machine shop at ground level and a 100-ton crane provides for handling of equipment during erection or overhaul.

The main turbines are 20,000-kw., fourteen-stage, 1,800-r.p.m., single-cylinder, General Electric units designed for steam pressure and temperature of 375 lb. gage and 700 deg. F. at the throttle and arranged for bleeding from the third, seventh and eleventh stages. A constant supply of clean oil for the turbines is provided by a continuous by-pass filtration system and the oil is cooled in surface coolers using condensate or house service water for the cooling medium. On each of the turbine gage boards are mounted transmitting and receiving telegraphs connecting with the control house, main steam and first stage pressure gages and vacuum

## Principal Equipment in the Trinidad Steam-Electric Station

### TURBO-GENERATORS AND AUXILIARIES

*Turbo-Generators*—Two General Electric. Turbine, 20,000 kw., 1,800 r.p.m., fourteen stage, bleeding at third, seventh and eleventh stages. Generators, 25,000 kva., 12,000 volts, three phase, 60 cycles. Main exciters, direct connected, 120 kw., 250 volts, shunt wound. Steam flow meter, two General Electric, one per turbine.

*Condensers and Auxiliaries*—Two Wheeler Condenser & Engineering Company. Surface, 20,000 sq.ft. each, horizontal, single pass, one floating tube sheet, Admiralty metal tubes; tubes rolled into both tube sheets.

*Circulating Pumps*—Four Wheeler Condenser & Engineering Company (2 per condenser); centrifugal, 20,000 g.p.m. (44.5 c.f.s.) against a total head of 21 ft.; each driven by a 150-hp., 2,200-volt, three-phase, two-speed General Electric induction motor.

*Condensate Pumps*—Four Wheeler Condenser & Engineering Company (2 per condenser); centrifugal, 440 g.p.m. (220,000 lb. per hour) against a 210-ft. head; each driven by a 40-hp., 2,200-volt, three-phase General Electric induction motor.

*Generator Air Coolers*—Two General Electric, each 15,000 sq.ft., fin type.

*House Turbine*—One General Electric. Turbine, 1,200 kw., single stage, 3,600 r.p.m., non-condensing. Generator, 1,500 kva., 2,300 volts, three phase, 60 cycles. Exciter, direct connected, 17 kw., 250 volts, compound wound.

*Auxiliary Exciter*—One General Electric; 150 kw., 250 volts, shunt wound; direct connected to General Electric 225-hp., 2,200-volt, 1,200-r.p.m., squirrel-cage induction motor.

### BOILERS AND AUXILIARIES

*Boilers*—Four Babcock & Wilcox, sectional cross-drum water tube. Heating surface, 18,756 sq.ft. Working pressure, 425 lb. gage.

*Superheaters*—Four Babcock & Wilcox; interdeck, 4,000 sq.ft., three pass. Total steam temperature. 750 deg. F.

*Furnaces*—Four Combustion Engineering Corporation; Lopulco water cooled. Heating surface of water walls, 2,520 sq.ft. Arches, American Arch Company. Furnace volume, 18,540 cu.ft. above ashpit screen.

*Primary Air Fans*—Four B. F. Sturtevant Company; each driven by a 75-hp., 1,800-r.p.m., 2,200-volt General Electric induction motor.

*Soot Blowers*—Diamond Power Specialty Company; 22 per boiler.

*Soot Ejectors*—Four Girtanner Engineering Corporation; steam jet conveying.

*Boiler Meters*—Four Bailey Meter Company; D-26, 0-200,000 lb. per hour. Recording steam flow, air flow, steam temperature and flue gas temperature; also indicating steam flow.

*Boiler Feed Pumps*—Three A. S. Cameron Steam Pump Works; No. 5 H.S.T., six stage, 700 g.p.m. (350,000 lb. per hour) each, against 1,155-ft. head; each driven by 350-hp., 2,200-volt General Electric induction motor. One A. S. Cameron Steam Pump Works H.M.T., five stage, 700 g.p.m., against 1,155-ft. head; driven by 340-hp. Terry turbine, type GS.

*Heaters*—Wheeler Condenser & Engineering Company; horizontal closed type, floating head; two eleventh stage, 750 sq.ft.; two seventh stage, 837 sq.ft.; two third stage, 1,290 sq.ft.; two Gland steam, 287 sq.ft.

*Evaporators*—Two units, Wheeler Condenser & Engineering Company; Contraflo, single effect, two per unit; capacity per unit 10,000 lb. per hour; equipped with Atwood & Morrill drainers, Cochrane 9,000-lb.-per-hour deaerating heater and 820 sq.ft. high-heat level condenser.

*Evaporator Feed Pumps*—Three Goulds Manufacturing Company; centrifugal, 30 g.p.m. against 145-ft. head; each driven by a 5-hp., 220-volt General Electric induction motor.

### FUEL PREPARATION, BURNING AND HANDLING EQUIPMENT

*Track Scale*—One Fairbanks Company; capacity 250,000 lb.

*Weightometers*—Two Merrick Scale Manufacturing Company; capacity, 100 tons per hour each.

*Apron Feeders*—Two Stephens-Adamson Manufacturing Company; capacity, 100 tons per hour each; each driven by a 7½-hp., 220-volt General Electric induction motor.

*Crushers*—Two units, Stephens-Adamson Manufacturing Company; two crushers per unit. Single roll, Pennsylvania Armorframe, 24x50 in. with vibrating screens between primary and secondary crushers; each crusher driven by a 50-hp., 220-volt General Electric induction motor.

*Elevator Conveyors*—Two Stephens-Adamson Manufacturing Company; V bucket type, 100 tons per hour each; each driven by a 25-hp., 220-volt General Electric induction motor.

*Belt Conveyors*—Four Stephens-Adamson Manufacturing Company; each driven by a 5-hp., 220-volt G.E. induction motor.

*Pulverized Fuel Conveyors*—Six Combustion Engineering Corporation; screw; 20 and 25-hp., 220-volt G.E. induction motors.

*Lignite Storage Equipment*—Stephens-Adamson Manufacturing Company; Crescent drag scraper; 75-hp., 2,200-volt General Electric induction motor.

*Driers*—Four Combustion Engineering Corporation; steam grid, four stacks each, 45 grids per stack.

*Pulverizing Mills*—Four Combustion Engineering Corporation; six-roll Raymond, 15 tons per hour each; each driven by a 200-hp., 2,200-volt General Electric double-squirrel-cage-induction motor.

### ASH-HANDLING EQUIPMENT

*Ash Conveyors*—Combustion Engineering Corporation; Combusco water seal drag.

*Ash Skip Hoist*—Stephens-Adamson Manufacturing Company.

*Ash Bunker*—Stephens-Adamson Manufacturing Company.

*Ash Cars*—Three Western Wheeled Scraper Company; 30-yard, with extended sides to give 45-yard capacity.

### MISCELLANEOUS

*Pumps*—Make-up for lake water, Worthington Corporation. Fire pumps, Allis-Chalmers company. House service, Allis-Chalmers company. Surge tank and sump, Goulds company. Domestic water supply, American Well Works.

*Air Compressor*—One Ingersoll-Rand Company; two stage, belt driven, 384 cu.ft. air at 110 lb. gage; driven by 100-hp., 2,200-volt Westinghouse induction motor.

*Turbine Room Crane*—Whiting Corporation; 100 ton.

### ELECTRICAL EQUIPMENT

*Main Transformers*—Seven Westinghouse, 8,333 kva. each, 136,800/64,800Y, 12,000 delta-volt, single-phase, water-cooled, outdoor type.

*Auxiliary Transformer*—Three General Electric, 2,000 kva., 12,000/2,300 volts, three phase, self-cooled.

*Standby Auxiliary Transformer*—One General Electric, 2,000 kva., 60,000Y/2,300 volts, delta, three phase, self-cooled.

*Auxiliary Transformer*—General Electric, 2,300-115/230 volts, single phase, oil cooled, six 150 kva., sixteen 100 kva., four 37½ kva., three 25 kva.

*132-kv. Synchronizing Equipment*—General Electric; condenser type, with vacuum tube amplification.

*Oil Circuit Breakers and Disconnect Switches*—Pacific Electric Manufacturing Company.

*Grounding Switches and Choke Coils*—Burke Electric Company.

*Direct-Current Control Power*—Storage battery, Electric Storage Battery Company; E-17, 60 cell, 120 volts, 320 amp.-hr.

*Motor-Generator Sets*—Two General Electric; 35 kw. each.

*Battery Charger*—One G.E.; motor-generator, 5 kw., 140 volts.

*Switchboards and Control Panels*—General Electric.

---

gage, mercury column vacuum gage, synchronism indicator, lubricating oil and condenser temperature recorders, turbine speed indicator, indicating wattmeter, generator air temperature indicator with alarms and lubricating oil temperature alarm.

Each turbine exhausts into a 20,000-sq.ft. single-pass surface condenser having Admiralty metal tubes and Muntz metal tube sheets. Two 30-in. circulating pumps are provided for each condenser, each rated at 20,000 g.p.m. (44.5 c.f.s.) and driven by 150-hp., 2,200-volt, 300-240-r.p.m. squirrel-cage induction motors.

The most interesting and unusual features of the condensing equipment is the floating tube sheets in the condensers. The tubes are expanded into both of the tube sheets, one of which is mounted on rollers and connected to the shell by a rubber expansion ring. This construction eliminates packing of condenser tubes and assists in keeping condenser leakage at a minimum.

The house turbine is a 1,200-kw., 3,600-r.p.m., single-stage, non-condensing unit designed to take steam at the same condition as the main units. This turbine is especially adapted for operation as a station auxiliary protection unit, and when operated as such the turbine carries no load and the generator floats on the auxiliary bus as a synchronous condenser. When this unit is floating on the line the turbine windage is reduced to a minimum by connecting the exhaust to one of the main condensers. A 3 per cent drop in frequency causes this unit immediately to pick up load up to 1,200 kw.

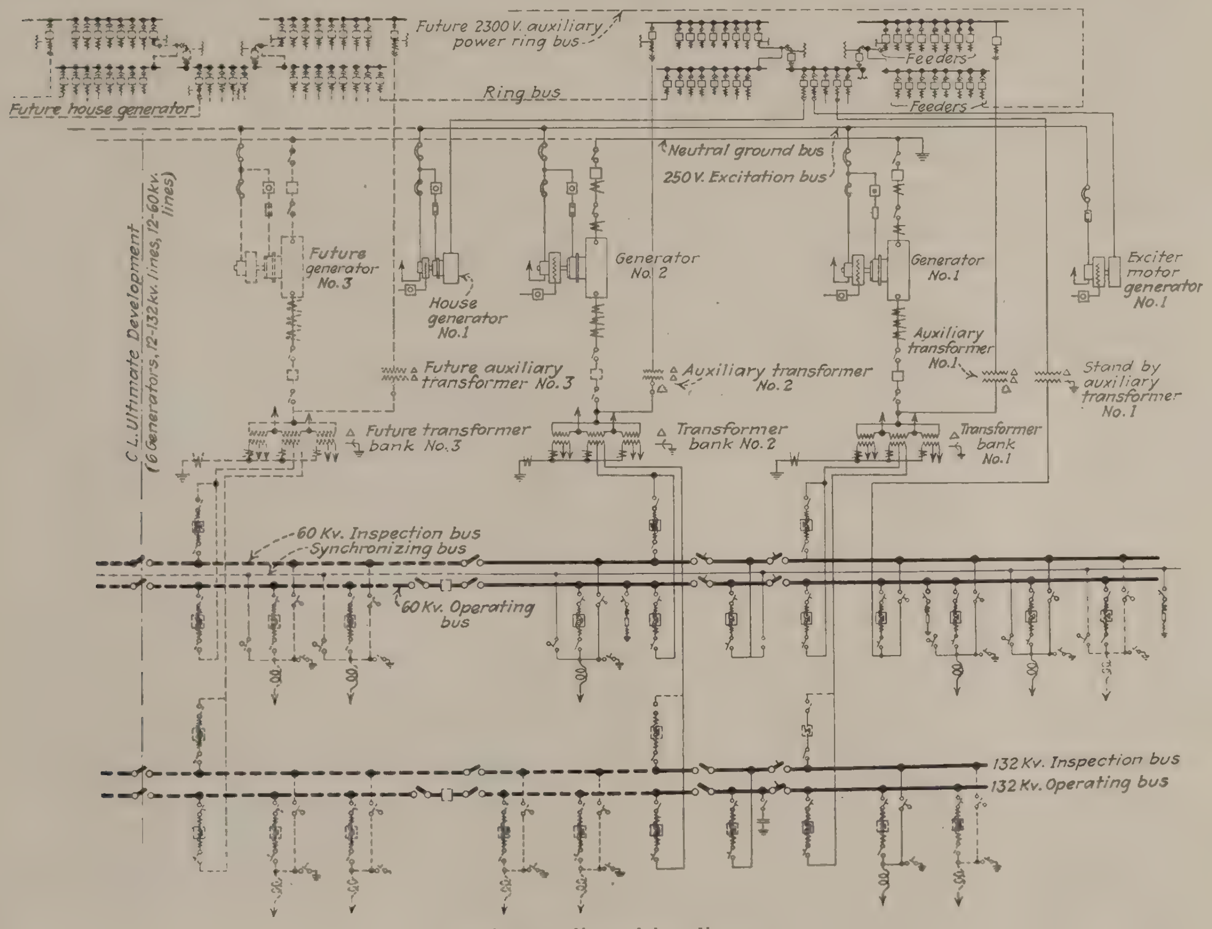
### ELECTRICAL FEATURES OF PLANT

Both of the present generators are 25,000-kva., 12,000-volt, star-connected units with neutrals grounded through non-automatic, remote-controlled oil circuit breakers. Each generator is connected directly to a bank of three 8,333-kva. outdoor, water-cooled transformers which are wound for 60,000 and 132,000 volts on the high side.

All of the control and metering equipment is located in the control house, which is 130 ft. west of the main building between the 60-kv. and the 132-kv. switch structures. Besides metering panels and control benchboards for the generators, 60-kv. feeders and 132-kv. feeders the control house is equipped with turbine room telegraph, steam gage and exciter control panel. All switching is done at 60 kv. and 132 kv. All oil circuit breakers and the main disconnects are motor-operated and controlled from the benchboards in the control house. A condenser type synchroscope with vacuum tube amplifier is provided for synchronizing at 132 kv. and an ordinary synchroscope using potential transformers is used for the 60-kv. circuits. Control current is furnished by a storage battery in the control house basement. This battery also furnishes current for emergency lighting.

### Switch Structures

The present switch and feeder structures are built to accommodate six 60-kv. feeders and two 132-kv. feeders, but only four 60-kv. feeders and one 132-kv. feeder are now in operation. The design provides for an ultimate development of twelve 60-kv. feeders and twelve 132-kv. feeders. The 60-kv. switching structure is arranged with duplicate buses, an inspection bus and an operating bus. Each generator transformer bank is connected directly to each of these buses through remote-controlled automatic oil circuit breakers. Both the operating and inspection buses are tied between each generator section by short-sectionalizing buses with gang-operated disconnects. The operating and inspection sectionalizing buses are in turn connected by a remote-controlled automatic circuit breaker. Each feeder is connected to the operating bus through a remote-controlled automatic circuit breaker and to the inspection bus by a motor-operated disconnect switch. The 132-kv. structure and bus is similarly arranged except that the generator connection to the inspection bus and feeder circuit breaker have been omitted for the present, as only one feeder has been placed in operation.



*Station one-line wiring diagram*

Station auxiliary power is normally taken from each generator lead by a 2,000-kva., three-phase, 12,000/2,300-volt transformer. When neither machine is operating, or these transformers are not in service, auxiliary power is taken from the 60-kv. bus by a 2,000-kva., three-phase, 60,000/2,300-volt transformer. In case of failure of both of these sources the auxiliary load is carried by the house turbo-generator, which, if it is floating on the auxiliary bus, will take load automatically, as previously explained.

The 2,300-volt auxiliary panels are of the truck type and are located in a concrete compartment in the basement of the auxiliary bay. The present 2,300-volt bus is divided into five sections, three general service buses and two unit auxiliary buses. Each unit auxiliary bus is connected directly to one of the 12,000/2,300 auxiliary transformers and from it are fed the circulating and condensate pumps for one turbine, one primary air fan, two pulverizer mills and mill exhausters and the 220-volt load centers for the fuel feeders, drier auxiliaries and sump pumps, the 220-volt buses in the drier and feeder load centers being in duplicate, and each connected to a different 2,300-volt bus, so that the drier fan and feeder motors may be supplied from either of these sources. When both units are operating, one group, or half of the feeders for each boiler, is connected to one unit bus and the other group to the other unit bus to prevent complete loss of fires under any boiler in case one unit trips off or is shut down without tying the auxiliary bus for that unit to the general bus. The three motor-driven boiler feed pumps, general 2,200-volt auxiliaries and 220-volt load centers are divided between the three sections of the general bus. The house generator and the 60,000/2,300-volt auxiliary transformer feed to the center section of the general bus, which also serves as a tie between each end group, consisting of one general and one unit auxiliary bus. Similarly arranged buses are to be installed with each pair of generators and a ring bus formed by connecting the ends of the general buses. The lighting panels are divided between the three general buses and when the alternating current supply fails some are automatically transferred to the 125-volt direct-current bus to serve as emergency lights.

All motors are 2,200-volt or 220-volt, constant-speed, squirrel-cage type, with the exception of the circulating pump motors, which are two-speed motors. In general, all motors smaller than 50 hp. are 220-volt and those 50 hp. and larger 2,200-volt. There are, of course, exceptions, such as the 40-hp., 2,200-volt condensate pump motors and the 50-hp., 220-volt motor-generator and crusher motors. Motors driving the boiler feed, evaporator feed, circulating water, condensate, transformer circulating water, fire, drip and sump pumps and the primary air and drier exhauster fans are equipped to restart automatically after an interruption. Other motors must be manually restarted.

An intake house for cooling water, a machine shop and an operators' village on the plant site are added features of the station. The station office, locker rooms and a water-treating laboratory are other features which go to complete the project.

## Job Cost of 1,600-Kw. Hydro Plant $158 per Kilowatt

DATA for a 1,600-kw. generating station built at Marlboro, N. H., for the Keene Gas & Electric Company by L. H. Shattuck, Inc., Manchester, N. H., have been released. The plant consists of two 800-kw., 2,300-volt General Electric generators connected to S. Morgan Smith horizontal waterwheels delivering 1,429 hp. each when using 56 c.f.s. at 260.6-ft. head, Woodward governors, a reinforced concrete generating station building, outdoor substation, steel surge tank 12 ft. in diameter and 8 ft. high, redwood penstock 4 ft. in diameter and 5,800 ft. long (staves $1\frac{9}{16}$ in. and $2\frac{1}{16}$ in. thick), including three steel bends in a gorge, and a partially reinforced concrete arch dam 60 ft. high, with arched portion 175 ft. long on top, 22-ft. gravity section at one end and a 45-ft. spillway section, the thickness at the base being 12 ft. thick and the top 4 ft. The total cost of this job, excluding office overhead, office supervision, engineering costs and construction profits, was $252,618.59, itemized as shown in the accompanying table.

DATA ON HYDRO PLANT COSTS, MARLBORO, N. H., 1923

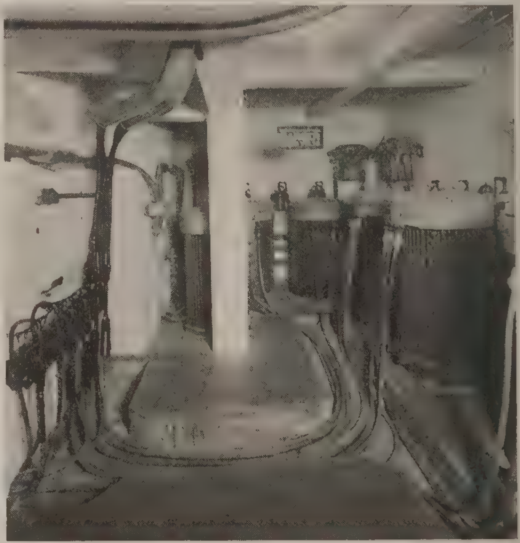
| | |
|---|---|
| **Unit Costs** | |
| Excavating earth and loose rock at dam site, including clearing and stripping, per cubic yard | $4.03 |
| Foundation trenches in solid rock, per cubic yard | 10.67 |
| Cost of forms, including material, placing, stripping, moving, etc., and expansion joints per face foot | 0.34 |
| Mixing and placing concrete, per cubic yard | 2.75 |
| Reinforcing steel in place, per pound | 0.06 |
| Earth excavation per foot of penstock line | ... |
| Rock excavation per foot of penstock line ($4.32 per cubic yard) | 0.82 |
| Timber trestles, per foot (local timber) | 2.66 |
| Concrete bases for cradles, per foot of line | 1.76 |
| Reinforced concrete cradles in place, each | 4.07 |
| Redwood cradles in place, each | 5.50 |
| Penstock in place, head range 30 to 260 ft., average per foot | 6.85 |
| Haulage and distribution of materials for penstock, per foot | 0.55 |
| **Total Costs Main Items** | |
| Dam | $71,623.18 |
| Penstock | 81,130.54 |
| Surge tank | 4,290.00 |
| Power house and tailrace | 34,488.81 |
| Hydraulic equipment | 23,192.80 |
| Electrical equipment | 16,846.14 |
| Outdoor substation and switching station | 10,075.62 |
| Railroad riprap | 6,318.31 |
| Rights-of-way | 4,653.19 |
| Total | $252,618.59 |

## Floor Trenches Aid in Racking Cables

By T. W. Swartz

*Assistant Engineer Northwestern Electric Company, Portland, Ore.*

OF THE several methods of racking cables in transformer vaults all have been discarded by the Northwestern Electric Company, Portland, Ore., in favor of that shown in the accompanying illustration. As will be seen, floor trenches are provided which may be covered either with smooth or $\frac{1}{4}$-in. checkered plate broken up into easily removable sections. Formerly cables were racked on the walls of the vault.



*Neat, safe and economical layout provided by laying cables in floor trenches*

The trench method of racking has been found to have the following advantages:

1. If heavy secondary cables are required the saving in cable to reach a junction box or busing point is very material, much more than offsetting the additional work necessary in the floor.
2. Less labor in placing and racking cables.
3. Greater safety because the cables can be completely placed out of the way for shifting transformers.
4. Complete separation of high and low voltage cables is obtained so that failure on one class cannot affect the other.
5. Secondary cables are much more accessible for changes in case of increase in size after the original installation.
6. All things considered, this method has proved more economical than the older method.

# Loads from Looped or Tapped High-Tension Feeders

## Effect of such conditions on one of several paralleled lines, with particular reference to underground cable systems

By H. L. Wallau
*Electrical Engineer, Cleveland*

HIGH-TENSION loads may be taken on a system in one of three ways: (a) Radial lines from supply stations to the loads; (b) existing lines between stations may be looped through the loads; (c) existing lines between stations may be tapped and tap lines extended to the load.

When method (a) is used the lines supplying the station from which the radial feeds are run have their loading increased in direct proportion to the added load. When method (b) is used, if there is more than one line feeding the supply station, the loading of the direct lines may be greatly distorted after adding the looped load. The same is true of method (c).

Since the latter method affects the division of load between the supply lines, it is desirable to know to what extent such unequal division may create unfavorable operating conditions. This is especially true of underground cable systems in which the thermal characteristics of cable and subway, rather than conductor section or voltage drop, limit the load which may be carried on a given line.

To this end the following closely approximate method is suggested. The figure shows a typical looped load diagram, as well as one for a tapped load:

$n$ = number of paralleled lines between stations.
$Ra$, $Rb$, etc., $Xa$, $Xb$, etc., $Za$, $Zb$, etc. = respective constants in ohms.
$Zm$ = combined parallel impedance.
$Pr$ = power delivered to receiving station, in kilowatts.
$\cos\phi$ = power factor of receiving station load.
$E$ = delivered voltage phase-to-neutral.

Then the total current per phase at the receiving station before adding the looped load is—$Ir = Pr/3000\,E\cos\phi$.

The total impedance drop is $Ir\,Zm$.

The current in each line is $Ia = Ir\,Zm/Za$, $Ib = Ir\,Zm/Zb$, etc.

Considering the effect of adding the looped load, let the looped line be lettered —$n$. Its constants are

$$Rn = Ro + Rn - Ro$$
$$Xn = Xo + Xn - Xo$$
$$Zn = Zo + Zn - Zo$$

where $Ro$, $Xo$, $Zo$ are the constants from sending station to customer's premises.

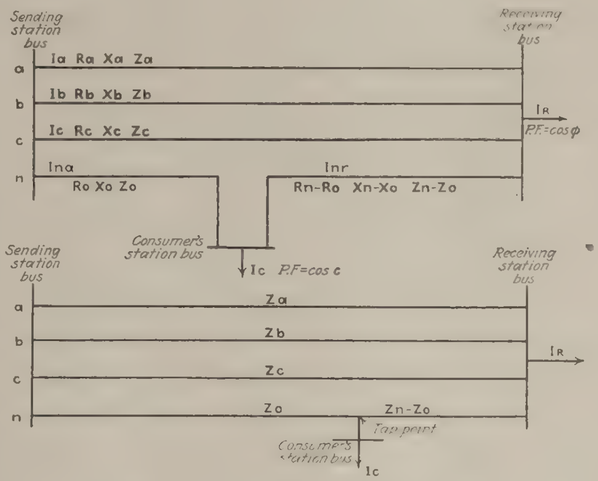
Let the customer load be $Pc$ at power factor $\cos c$, current $Ic$.

The regulation between sending station and consumer's premises is due to two components of current, the consumer's load current and the portion of the receiving station current flowing over the looped line. Under certain conditions this latter current may be negative; that is, part of the consumer's load may be furnished directly from the sending station and part may flow from sending station to receiving station and back to consumer's premises.

The regulation between sending station and receiving station is due to the two preceding components plus the receiving station component over the portion of the line between consumer's station and receiving station. The regulation from sending to receiving station over this line can also be considered as due to a fictitious load at consumer's power factor flowing to the receiving station combined with the above-mentioned component of receiving station load.

The regulation due to the consumer's load may be computed by the usual formula:

$$\text{Reg. }(c) = Ic\,Ro\cos c + Ic\,Xo\sin c + \frac{(Ic\,Xo\sin c - Ic\,Ro\cos c)^2}{200} = Vc \text{ volts}$$



*Typical looped and tapped load circuits*

Substituting $Rn$ and $Xn$ in the preceding formula and solving for the fictitious current $I_f$ produces the same regulation $Vc$. For the fictitious condition set up the receiving station load becomes $Ir + I_f$ (vectorial addition), hence the total current $I_t$ for these conditions may be determined. The current over each line would then be

$$Ia = It\,Zm/Za$$
$$In = It\,Zm/Zn, \text{ etc.}$$

But,

$$Ir - Ia - Ib - \dots\dots\dots - I(n-1) = Inr$$

the receiving station component of $Ir$ at power factor $\cos\phi$ flowing over line $n$.

And

$$Ina = Inr + Ic \text{ (vectorial addition)}$$

in which $Ina$ is the actual current flowing out from the sending station to the consumer station, $Ic$ the consumer's load current and $Inr$ the balance flowing from the consumer's station to the receiving station.

If the introduction of the looped load necessitates an increase in circuit length of the line $n$ the constants for the increased length of looped line must be used in making the calculations.

### SOLUTION OF TAPPED LOAD EFFECT

In the solution of tapped lines, the method is the same, the values of $Ro$, $Xo$, $Zo$ being computed to the tap point. There is, of course, additional regulation to the consumer's load over the tap line extension.

To illustrate, assume a receiving station having a load of 600 amp. per phase at a power factor of 71 per cent to be fed by four No. 4/0 12,000-volt cables having impedances as follows: $Za = 1.74$, $Zb = 1.91$, $Zc = 2.08$, $Zn = 1.74$, $Zm = 0.464$. Under these conditions the division of current will be: $Ia = 160$, $Ib = 146$, $Ic = 134$, $In = 160$, $Ir = 600$.

Assuming that it is desired to loop a load of 100 amp. per phase at 80 per cent power factor through line $n$ at such a point that $Ro = 0.55$, $Xo = 0.42$, $Zo = 0.70$, the regulation due to this load to the consumer's premises is 88.5 volts. Solving for the fictitious equivalent current $I_f = 48$ amp.

Then

$$\begin{array}{lll} Ir = 600 & Ir \cos\phi = 426 & Ir \sin\phi = 426 \\ I_f = \phantom{0}48 & I_f \cos c = \phantom{0}38 & I_f \sin c = \phantom{0}29 \\ \hline I_t = 650 & \phantom{Ir \cos\phi = }464 & \phantom{Ir \sin\phi = }455 \end{array}$$

For $I_t = 650$ the line currents are: $Ia = 173.5$, $Ib = 158$, $Ic = 145$, $In = 173.5$, $It = 650$.

$$Ir\text{-}Ia\text{-}Ib\text{-}Ic = Inr = 600 - 476.5 = 123.5$$

Before adding the looped load lines a, b and c carried 440 amp. of the receiver station load. After adding the looped load the same lines carry 476.5 amp. The difference of 123.5 amp. is superimposed at the sending station on the 100 amp. of customer load and the current flowing over line $n$ is, therefore,

$$\begin{array}{lll} Ic = 100 & Ic \cos c = 80 & Ic \sin c = 60 \\ Inr = 123.5 & Inr \cos\phi = 88 & Inr \sin\phi = 88 \\ \hline Ina = 230 & \phantom{Inr \cos\phi = }176 & \phantom{Inr \sin\phi = }148 \end{array}$$

The currents after adding the looped load then are: $Ia = 173.5$, $Ib = 158$, $Ic = 145$, $Ina = 230$.

The next step is to repeat the calculation with each of the various lines down to see whether or not under emergency conditions the maximum safe current loading on any cable will be exceeded. The division of load prior to the addition of the looped load need not be computed, but it was done here to clarify the discussion.

## Size Important in Brush Replacements

By M. E. Reagan
*Switchboard Engineer*
*Westinghouse Electric & Manufacturing Company*

THE operation of each device used in automatic switching equipment depends on the proper functioning of some previously actuated relay. Manufacturers accordingly give careful attention to the design details and service characteristics of these relays, realizing that failure of any one means a "black eye" for the entire switching equipment.

Some automatic switching schemes use a small polarized motor-driven relay to check the polarity of a synchronous converter before placing the unit on the line. If the converter polarity is right the small two-brush motor rotates in one direction, if the polarity is wrong the motor operates in the opposite direction.

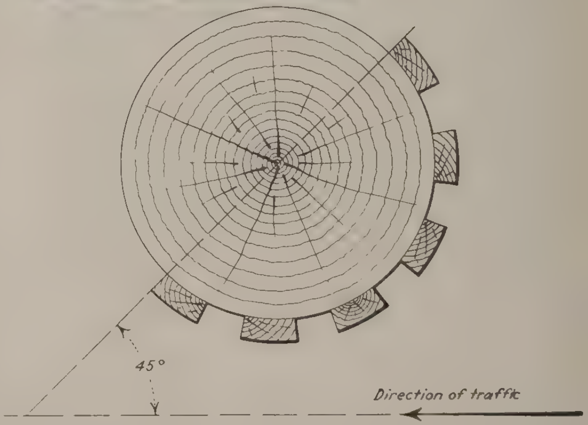
In time the brushes wear out and are often carelessly replaced by those of smaller size. Trouble begins here, although the motor may operate successfully for several months. If there is a small amount of play between the carbon brush and the brush-box or holder, the brush will assume a leaning position, depending upon the direction of rotation. Since such a motor operates for approximately equal periods in each direction, the brush will wear to a shallow letter "V" on the commutator end. This means that the brush will ride momentarily on the middle point every time the motor is called upon to reverse its direction of rotation. As the point wears to a distinct ridge, it will sooner or later come to rest on the mica insulation between the commutator bars and an open motor circuit will result.

To prevent such failures it is necessary, first, slightly to undercut the mica below the surface of the commutator bars, and, second, to use a brush with but a small clearance in the brush-holder. This amount of clearance should be just enough to allow the brush to move axially within the holder without excess friction.

## White Strips Make Poles Conspicuous to Traffic

By R. E. Cunningham
*Farnham & Cunningham, Los Angeles, Cal.*

PAINTING poles white for about 6 ft. above the ground so that they will be conspicuous, particularly at night, has been practiced by power companies for several years in an effort to aid in the reduction of automobile accidents. As it is impracticable to attempt to use white paint on full-length creosote pressure-treated wood poles it has been necessary to devise another method to accomplish the desired results. It has become quite common practice on railroad crossing gates, boulevard stop signs, etc., to use alternate black and white stripings to attract attention. This same barber pole effect has been obtained on black creosoted poles by nailing white battens around them, as shown in the accompanying illustration. This method has been approved by the California State Highway Commission for use on poles located on highways. The size of the battens is $\frac{3}{4}$ in. x $2\frac{1}{2}$ in. x 5 ft. They need be placed around only half the circumference of the pole, facing the direction of traffic.



*White wood strips on creosoted poles offer inexpensive and simple means of warning autoists of danger*

# Puncture Tests Affected by Strength of Oil

By J. T. Littleton, Jr., and W. W. Shaver
*Corning Glass Works*

The A.I.E.E. specifications for testing insulators[1] call for a puncture test while the latter are immersed in insulating oil. Practically all tests on the dielectric strength of insulating materials in general are made under such conditions. The only reason for immersion is to prevent a flashover before the voltage is high enough to produce a puncture. The oil, of course, has a dielectric constant different from air and the electrostatic field of force surrounding the insulator is accordingly changed by immersion in the oil. In the case where insulation is to be used in air a test under oil therefore introduces an artificial condition which should not be accepted if it can be shown that results under oil are not equivalent to those in air.

Experiments recently described by the authors[2] show that the puncture of an insulator in regular insulating oil is preceded by a breakdown of the oil, which is instrumental in causing the puncture. The question of the extent of the effect due to such oil failure is of prime importance. If dielectric failure under oil takes place at a much lower voltage than in air, then the conditions of the oil puncture test should be modified so as to approximate air conditions.

The experiments described below were made to furnish information on this subject; that is to say, to determine the effect of the dielectric strength of the oil on the puncture voltage of an insulator under oil. In these experiments a given lot of insulators were subjected to three high potential tests in the following order: (1) In air at a pressure of about 60 lb. per square inch; (2) in special steam-treated oil up to the potential used in (1), and (3) in regular insulating oil. After each of the first two tests the insulators were all subjected to an over-potential flashover test at 112 kv. for five minutes with no resulting failures, showing that they had not been damaged by partial punctures in either of the high potential tests. In the third test in the regular insulating oil the insulators were all punctured.

Fourteen Pyrex insulators with a rated dry flashover of 82 kv. (25-deg. C., 760-mm. pressure, 60 per cent relative humidity) were selected for these tests from rejections on account of having less than the standard head thickness so as to have low puncture values. These insulators were subjected, one after another, to the three high potential tests as stated above and all fourteen were tested simultaneously in the two table flashover tests at 112 kv. for five minutes with no resulting failures. All the tests were made with a 150-kva., 300-kv. transformer, with the center grounded and the voltage controlled by an induction regulator.

TABLE I—COMPARATIVE FLASHOVER POTENTIALS IN THREE MEDIUMS

| Ins. No. | Maximum Potential in Air Chamber, Kv. | Remarks | Maximum Potential in Steam-Treated Oil, Kv. | Remarks | Maximum Potential in Regular Oil, Kv. | Remarks |
|---|---|---|---|---|---|---|
| 1 | 140.5 | (a) | 150 | No puncture | 108 | Punctured |
| 2 | 144.5 | (a) | 150 | No puncture | 106 | Punctured |
| 3 | 146 | (a) | 150 | No puncture | 100.5 | Punctured |
| 4 | 143 | (a) | 150 | No puncture | 102 | Punctured |
| 5 | 136.5 | (b) | 150 | No puncture | 108 | Punctured |
| 6 | 141.3 | (a) | 150 | No puncture | 108 | Punctured |
| 7 | 142 | (a) | 150 | No puncture | 111 | Punctured |
| 8 | 142 | (a) | 150 | No puncture | 108 | Punctured |
| 9 | 156 | (a) | 150 | No puncture | 109.5 | Punctured |
| 10 | 160 | (b) | 150 | No puncture | 118 | Punctured |

| 12 | 148 | (a) | 150 | No puncture | 107 | Punctured |
| 13 | 150 | (a) | 150 | No puncture | 104 | Punctured |
| 14 | 142 | (a) | 150 | No puncture | 108 | Punctured |
| Average | 146 | | 150 | | 107.5 | |

(a)—Flashover occurred between leads outside the chamber.
(b)—Flashover occurred inside chamber over the insulator.

TABLE II—PUNCTURE TESTS IN OIL OF TWO DIELECTRIC STRENGTHS

| Ins. No. | Maximum Potential in Steam-Treated Oil, Kv. | Remarks | Maximum Potential in Regular Oil, Kv. | Remarks |
|---|---|---|---|---|
| 1 | 193 | No puncture | 105 | Punctured |
| 2 | 184.5 | Punctured through lower skirt | 132 | Punctured |
| 3 | 179 | No puncture | 117 | Punctured |
| 4 | 205.5 | No puncture | 106.5 | Punctured |
| 5 | 202 | No puncture | 104 | Punctured |
| 6 | 200 | No puncture | 109.5 | Punctured |
| 7 | 200 | No puncture | 103 | Punctured |
| 8 | 200 | No puncture | 105 | Punctured |
| 9 | 200 | No puncture | 109.5 | Punctured |
| Average | 196 | | 110 | |

The steam-treated oil was regular insulating oil with water suspended in it, introduced by bubbling steam through the oil for a few seconds, until the dielectric strength of the oil was reduced to about 17 kv. for a 0.2-in. gap between ½-in. electrodes. For the compressed air tests the electrode leading into the pinhole was insulated by a Pyrex heavy-walled tube so that the flashover took place from the bottom of the pinhole around the insulator to the wire in the tie wire groove. The insulator was mounted in a pressure chamber consisting of two Pyrex deck insulators clamped together with the two high-tension leads entering at the ends. The tests with respect to the initial applied voltage and rate of increase of voltage were made according to the A.I.E.E. specifications for a puncture test under oil. The air pressure in the chamber was about 60 lb. per square inch and the voltage was noted when flashover occurred either over the insulator or between the leads outside.

The five-minute table flashover tests were made with the electrodes in the pinhole, again insulated by Pyrex heavy-walled tubes, and the insulators mounted on small metal cans about 4 in. high, in order to raise the flashover potential to the maximum possible. For the oil tests the insulator was screwed on a pin, with a small amount of mercury in the pinhole to insure good contact between the pin and the insulator, and a short length of ½-in. brass rod was tied in the line groove with No. 8 A.W.G. copper wire. These tests were made according to the A.I.E.E. specifications with the exception that in the steam-treated oil the insulators were tested only to 150 kv. and not until puncture occurred.

Measurements on the dielectric strengths of the two oils used in the above tests made according to the specifications given by the A.S.T.M.[3] using ½-in. brass disk electrodes separated by 0.2 in. indicated a strength of 17 and 47 kv. for steam-treated and regular oil, respectively.

Inasmuch as these experiments did not show at what voltage the insulators would have punctured in air or under the steam-treated oil nine other insulators were selected for additional tests in the two oils. These insulators were first subjected to a high-voltage test in the oil of low dielectric strength and then they were punctured in the regular insulating oil of high dielectric strength.

---

[1] *A.I.E.E. Standards, Insulator Test Specifications, July, 1925.*

[2] *"Electrical World," Sept. 10, 1927, page 503.*

[3] *A.S.T.M. Standards, 1924, page 1070.*

The results in Table I show an average puncture voltage for the tests in the high-strength oil about 73 per cent of the average voltage that the insulators had previously withstood without damage in high-pressure air and in the low-strength oil. The results in Table II show an average puncture voltage in high-strength oil of 56 per cent of the voltage that the insulators had previously withstood in the low-strength oil. No corona was in evidence in the low dielectric strength oil tests, but it appeared when the voltage reached 80 kv. in the regular oil.

## Airplane Line Patrol

THE interconnected system comprising the properties of the Arkansas Power & Light Company, the Louisiana Power & Light Company and the Mississippi Power & Light Company contains about 1,000 miles of 110-kv. transmission, not to speak of 66-kv. and 33-kv. lines. The system covers large areas in the three states, and on this account the problem of transmission line inspection and maintenance is much more difficult than on a more compact system in a smaller area. Therefore a means for locating trouble faster than patrolling a line on foot—the lines do not follow the highways and therefore automobile patrolling is not wholly practicable—is much to be desired. An airplane seemed to be a reasonable solution.

*Plane owned and used by Arkansas Power Company. Observer accompanies pilot*

During the Mississippi flood last year H. C. Couch, president of the three companies, was most active in relief and levee protection work. Early in May of 1927 he secured the services of Allen Scott, a young pilot of Pine Bluff, Ark., who had his own airplane, to deliver sacks to locations where levees were threatened. Many of the transmission lines were in water up to 10 or 15 ft. deep, and after the flood had passed the crest and the danger to levees was past Scott made more or less systematic patrols of the lines to spot weakened construction and places where driftwood had accumulated against poles or towers. The line crews would then go out in rowboats or motorboats to make repairs or clean away the drift. After 1½ weeks of work in his own plane Scott was instructed to go to the factory of the Advance Aircraft Company at Troy, Ohio, and accept delivery of a Waco two-seater that Mr. Couch had ordered. This ship was used during the remainder of the flood period, and following that it became an integral part of the organization of the three companies.

The plane is not used for routine line inspection patrol. This is done on foot, as is the usual practice. But when a line goes out and it is necessary to find the trouble in the shortest possible time the plane is sent out. Since the flood emergency the airplane has located four line breaks, doing the job in each case in only a small fraction of the time that would have been necessary if the trouble had been hunted on foot or by automobile. It is the practice on this work for an observer to go along. In addition to line work the plane has been very useful in making emergency deliveries of small parts and equipments. General system dispatching is done by carrier telephone. One carrier installation in Mississippi got into trouble. Spare parts were available at a station in Arkansas. The plane made the delivery in a couple of hours and the communication system was immediately restored to normal operation upon the replacement of the defective parts.

In the period from May 4, 1927, to March 2, 1928, the plane traveled about 26,000 miles and was in the air about 300 hours. The motor was taken out and a new one installed after 225 hours. The first motor has been reconditioned and is now ready to replace the second when necessary. This work of reconditioning and changing motors is done by the pilot, who also added the cabin.

## Performance with Pulverized Coal

REPORTING an experience with pulverized coal firing at the Big Sioux station of the Sioux City Gas & Electric Company to the second Iowa Power Conference, J. E. Enerson, chief engineer of that company, presented the data shown in the accompanying table.

The installation is of the storage type firing Stirling boilers with economizers and bottom water screens. Steam pressure is 350 lb. with 240 deg. of superheat. Since starting operations in 1925, coal from ten states, Iowa, Kentucky, Illinois, Indiana, Arkansas, Oklahoma, Colorado, Missouri, Wyoming and Kansas, has been used. The variation was made more complete by the use of coal from several fields in each state. The Colorado coal was not lignite, but of the semi-bituminous variety; coal from the northern, central and southern districts of Illinois has been used; all Kentucky coal came from the western fields. These coals varied in moisture content from 2 to 20 per cent, in ash from 9 to 24 per cent and in B.t.u.'s per pound from 8,700 to 13,800. To make the range greater petroleum coke breeze having a B.t.u. value of more than 15,000 per pound and cinders with a B.t.u. value of from 2,600 to 3,000 per pound have been successfully burned. As a matter of fact, serious consideration is being given to the use of cinders in connection with a certain coal of fragile structure, the purpose of the cinders being to act as a cushion in the milling of this coal.

OPERATING EXPERIENCE WITH PULVERIZED FUELS

| **Coal** | 1926 | 1927 |
|---|---|---|
| Heating value | 10,990 | 10,610 |
| Moisture in coal, per cent | 9.45 | 10.15 |
| Ash in coal, per cent | 14.00 | 14.35 |
| Ash-fusing temperature | 2,200 | 2,200 |
| **Boiler** | | |
| Average rating, per cent | 179 | 197 |
| Boiler and economizer efficiency | 81.8 | 82.9 |
| **Coal Preparation** | | |
| Tons of coal pulverized per mill hour | 7.41 | 6.84 |
| Energy, kilowatt-hours per ton | 20.90 | 20.70 |
| Steam for heating coal house per ton, lb. | 73 | 73 |
| Total operating cost (labor, energy, material and heating steam), cents per ton | 26.75 | 26.08 |
| Total maintenance (labor, material), cents per ton | 8.56 | 12.00 |

# Breakdown of Spark Gaps

## Electrical characteristics at atmospheric pressure. Townsend theory contradicted. Temperature rise of 4,000 deg. C. produces great conductivity by thermal ionization

By Dr. J. Slepian
*Westinghouse Electric & Manufacturing Company*

*The great speed of breakdown of spark gaps at atmospheric pressures observed experimentally contradicts sharply the classical Townsend theory of sparkover. To solve this dilemma, it is suggested that thermal ionization of the gas takes place in the single passage of an electron from cathode to anode, and before the Townsend process can develop. Calculation, taking space change into account, confirms this view. Sparkover takes place at those gradients which produce thermal ionization, and good agreement is obtained between breakdown gradients calculated on this basis and those observed experimentally. The "suppressed discharges" figures of Torok, which are difficult to explain otherwise, are a natural consequence of the theory developed here. The time for breakdown with moderate overvoltages comes out satisfactorily of the order of $10^{-7}$ seconds.*

IN A very interesting and important paper W. Rogowski[1] has pointed out the inadequacy of the Townsend theory of electrical breakdown of gases for explaining the extreme shortness of the time in which breakdown of spark gaps in air at atmospheric pressures occurs. Whereas at voltages little greater than the static sparkover many experimenters[2] agree that the spark lag is of the order of $10^{-7}$ seconds, application of Townsend's theory leads to times of the order of $10^{-5}$ seconds. The basis of Townsend's theory, namely, the phenomenon of ionization by collision, is so well established in so many ways and Townsend's theory of breakdown itself is in such good agreement with experiments at lower pressures[3] that it seems necessary to continue to hold to it in accounting for the beginning of sparkover at atmospheric pressures, but to look for some new effect which short circuits the relatively slow Townsend process for explaining the extremely short time lag at atmospheric pressures.

According to Townsend, the mechanism of breakdown is as follows: Electrons move toward the anode, producing many ions by collisions on the way. The positive ions so generated move toward the cathode and also ionize by collision, although the capacity of the positive ion for ionizing by collision is much less than that of the electron. If, in moving toward the cathode, the positive ions are able to generate by collision electrons in number greater than those to which they owe their birth the discharge will be unstable, the current continually increasing so long as the impressed electric field remains the same. If $\alpha$ is the average number of ions generated by the collisions of an electron during its advance through one centimeter toward the anode, and if $\beta$ is the corresponding quantity for a positive ion, Townsend[4] gives for the steady state current flowing between plane electrodes in a uniform electric field below the breakdown value the following expression,

$$i = i_o \frac{(\alpha - \beta)\varepsilon^{(\alpha-\beta)d}}{\alpha - \beta\varepsilon^{(\alpha-\beta)d}} \qquad (1)$$

Here $i_o$ is the current which would flow if there were no ionization by collision and $d$ is the distance between the electrodes in centimeters. $\alpha$ and $\beta$ are rapidly increasing functions of the electric field, and as the electric gradient is increased the denominator in equation (1) becomes smaller. At a certain critical gradient the denominator becomes zero

$$\alpha - \beta\varepsilon^{(\alpha-\beta)d} = 0 \qquad (2)$$

and the current by equation (1) becomes infinite. According to Townsend, this critical gradient is the breakdown gradient, and for it and larger gradients there is no steady state current as in equation (1), but the current continues to increase without limit.

Essential to this briefly sketched theory is the ionizing action of the positive ions on their way to the cathode. The building up of the current during breakdown may be regarded as taking place in stages. First, electrons move toward the anode, generating many ions by collision. Then the positive ions move toward the cathode, generating a larger number of electrons. These electrons moving toward the anode generate a larger number of positive ions. And so the process continues. However, Rogowski shows that at atmospheric pressure, with a spark gap of one centimeter or more length, under breakdown conditions, a positive ion requires for moving from the anode to the cathode a time of the order of $10^{-5}$ seconds. Thus the theory leads to a very sharp contradiction with experiment.

The time required for an electron to move from cathode to anode is, according to Rogowski, of the order of $10^{-7}$ seconds and is more nearly in accord with experiments on time lag. There is a strong suggestion, then, that at atmospheric pressures the return of the positive ions to the cathode is unnecessary, breakdown occurring on the first passage of electrons to the anode.

---

[2] *For résumé of experimental work see article of Rogowski, l.c.*

[3] *Occasional observations of the time lag of spark gaps at reduced pressures which have come to the author's attention indicate that Townsend's theory gives correctly the order of magnitude of the time of breakdown.*

[4] *"Electricity in Gases," Oxford, 1915, page 313.*

Strengthening this suggestion, there are the very interesting pictures of "suppressed discharges" obtained by Torok,[5] one of which is reproduced on page 764. These pictures apparently show an impulse breakdown in the course of formation. We find here a number of luminous streamers of quite small section, originating in the more intense parts of the field next to the electrodes and growing out into the spark gap space. Presumably the breakdown occurs when a streamer bridges across the whole gap. The Townsend mechanism described above would seem to be inconsistent with such growing streamers. If the breakdown depended on many back and forth reactions of electrons and positive ions it would seem that the luminosity should develop more uniformly over the whole breakdown path, being faint in the early stages and then becoming more intense as the breakdown proceeded.

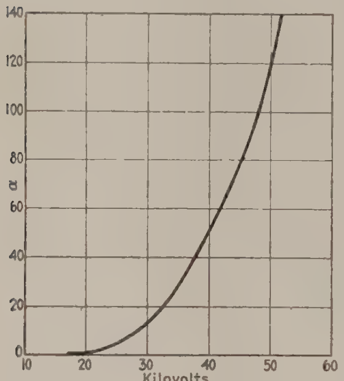

*Fig. 1—Values of α at atmospheric pressure*

### THERMAL IONIZATION THEORY

In this paper is brought out the fact that by calculation the energy density input into the gas in the path of an electron moving under the influence of an impulse breakdown field and ionizing by collision rises to enormous figures, and that consequently the gas in the neighborhood of the path is raised to a very high temperature. This temperature is so high that thermal ionization sets in, and it is by this thermal ionization that it is proposed to explain the speed of breakdown of spark gaps at ordinary pressures.

That gases at very high temperatures should be highly ionized is to be expected from kinetic and thermodynamic theory. Saha[6] has given this subject quantitative treatment and derived the following equation,

$$\log \frac{x^2}{1 - x^2} P = - \frac{U}{4.57\,T} + 2.5 \log T - 6.5 \quad (3)$$

where $x$ is the fraction of molecules ionized, $P$ is the pressure in atmospheres, $U$ is the energy required for ionization in calories per gram molecule and $T$ is the absolute temperature.

K. T. Compton[7] has applied Saha's equation to explain the conductivity of the space between the electrodes in an arc in air. He concludes that at the existing temperature, about 4,500 deg. K., there will be enough thermal ionization to account for the observed conductivity of about 50 amp./cm.$^2$ at a gradient of 27 volts/cm.[8]

In deriving his results from Saha's equation, Compton, of course, took $P = 1$. However, in the case of the spark discharge it is the density rather than the pressure which remains atmospheric, and at a temperature of 4,500 deg. K the pressure will increase to 15 atmospheres; $X$, the fraction of molecules ionized, will, therefore, by equation (3) be reduced in the ratio of $\sqrt{15}$. However, the number of molecules per centimeter$^3$ is increased fifteen times, so that the density of ions will be $\sqrt{15}$ times greater than at atmospheric pressure. The mobility of the ions will reduce at the higher pressure by approximately $\sqrt{15}$, so that the conductivity will not differ very much from that determined by Compton. We may conclude that a temperature rise of 4,000 deg. C. will be enough to produce great conductivity by thermal ionization.

### THE IONIZING CONSTANTS α AND β

The ionizing constants α and β, which are the average number of ionizing collisions made per centimeter travel in the direction of the field by the electrons and positive ions respectively, are important in the subsequent calculations. From kinetic theory considerations, it appears that the following functional relations hold.[9]

$$\frac{\alpha}{p} = f\left(\frac{X}{p}\right) \quad (4)$$

$$\frac{\beta}{p} = F\left(\frac{X}{p}\right)$$

Here $p$ is the gas pressure and $X$ the electric gradient. From these relations it is possible to calculate from the values of α and β found by Townsend and others for lower pressures what will be corresponding values at atmospheric pressures. Taking the data given by Townsend[10] and by Wheatley[11] we obtain the curve of Fig. 2.

Starting with a single electron, it is quite evident that ionization by collision will cause the number of electrons to multiply in an exponential manner. According to Townsend[12] the number of electrons generated by an initiating electron, and in its immediate neighborhood, when it has traveled a distance $x$ in the direction of the impressed field will be:

$$N = \varepsilon^{\alpha x} \quad (5)$$

### DIFFUSION OF ELECTRONS IN IONIZING PATH

To calculate the temperature rise in the gas due to the moving electrons whose number is given by (5) we must determine what is the cross-section of the path they traverse. If this path were a geometrical line, the temperature rise would be infinite. Actually the path will have a finite section due to the sidewise diffusion of the ions.

In his "Electricity in Gases," page 85, Townsend has shown that for particles spreading by diffusion, the mean square of the distances of the particles from any fixed point increases proportionally with the time. More particularly,

$$\overline{R}^2 = 6\,Dt \quad (6)$$

where $\overline{R}^2$ is the mean square of the particle distances, $D$ is the coefficient of diffusion of the particles and $t$ is the time.

We may regard the electrons of equation (5) as all moving together with a uniform velocity in the direction of the electric field, but that superposed upon this uniform velocity is a radial diffusion. Hence, we expect the electrons of (5) at any moment to have a spherical configuration. To simplify our calculations and for lack of any better hypothesis we shall assume that the electrons fill out a sphere of radius $R$ with uniform density.

It is readily verified then that $R^2 = \frac{5}{3}\overline{R}^2$ so that

$$R^2 = 10\,Dt. \quad (7)$$

[8] *K. T. Compton, loc. cit., page 286.*

[9] *Townsend, "Electricity in Gases," Oxford, 1915, pages 279 and 291.*

[10] *J. S. Townsend, Phil. Mag. (6), 27, 1914.*

[11] *Wheatley, Phil. Mag. (6), 26, 1913, page 1034.*

[12] *"Electricity in Gases," page 264.*

As to the coefficient of diffusion, Townsend's "Electricity in Gases," page 88, gives the formula $D = \frac{1}{3}\, lc$ where $l$ is the mean free path of the diffusing particles and $c$ is their effective velocity of agitation. Taking with Rogowski (l.c. page 501) $l = 5.70 \times 10^{-5}$ and $c = 1.09 \times 10^{7}$ we get $D = 2{,}070$.

The time $t$ in (7) is given by $\frac{x}{v}$ where $v$ is the velocity of the electrons in the direction of the field. Taking for this velocity $U = \sqrt{2\,\frac{e}{m}\,\frac{l}{\pi}\,E}$ and substituting numerical values and changing to practical units, $X$ being the electric gradient in volts per centimeter,

$$V = 2.53 \cdot 10^{5}\ X^{1/2} \qquad (8)$$

$$R^2 = 8.18 \cdot 10^{5}\ X^{-1/2} \qquad (9)$$

The mean density of electrons over the path section will be $N/\pi R^2$, but of course it will be greater at the center of the section. There it is readily seen it will be larger, namely,

$$n = \frac{3}{2\pi}\ N/R^2 \text{ electrons per square centimeter} \qquad (10)$$

When these electrons are pulled by the electric field through a distance of 1 cm. they will produce heat in amount $neX$, where $e$ is the electronic charge. To calculate the temperature rise, we must know the heat capacity of a cubic centimeter of air at high temperature, but at atmospheric density. Since experimental data are lacking for high temperatures we may use the kinetic theory. The molecules of a diatomic gas have three degrees of freedom in translation and two degrees of freedom in rotation. Also at high temperatures we must probably consider the oscillations of the atoms making up a molecule toward and away from each other, in which oscillations there will be kinetic and potential energy. From the principle of equipartition of energy it follows that the total energy of a molecule will be 7/3 times its kinetic energy. Taking for the translational energy per molecule, $2.058 \cdot 10^{-23} T$ joules and for the number of molecules per centimeter$^3$ $2.52 \cdot 10^{19}$, the heat content of a centimeter$^3$ of air at $T°\,K$ will be $1.20 \cdot 10^{-3} T$ joules. Hence,

$$neX = 1.20 \cdot 10^{-3} T \qquad (11)$$

$T$ being now the temperature rise.

Taking $e = 1.59 \cdot 10^{-19}$ coulombs and substituting (10), (9) and (5), in (11) we get

$$T = 7.82 \cdot 10^{-15}\ X^{3/2}\, x^{-1}\, \varepsilon^{\alpha x} \qquad (12)$$

This gives the temperature rise along the path of the ionizing electron. When $T$ equals 4,000 deg. the path becomes highly conducting because of thermal ionization. Equation (12) shows that for a given gradient the temperature rise increases very rapidly with $x$, and because of the dependence of $\alpha$ upon $X$ it increases very rapidly with $X$. In Fig. 2 are plotted the temperature rises for a few electric gradients.

If we assume tentatively that the critical gradient for breakdown of a plane electrode spark gap is that at which thermal ionization or a temperature rise of 4,000 deg. is reached, we get from Fig. 2 the gap lengths corresponding to various gradients shown in Table I. These may be compared with the experimental values considered best by Schumann, *Elektrische Durchbruchfeldstärke von Gasen,* Berlin, 1923, page 25. Although the proper order of magnitude is obtained, the spark lengths predicted by the tentative theory come out too long. It seems that we must look for some effect which sets in earlier than the thermal ionization, or which makes the thermal ionization set in earlier. This effect may be found in the influence of the space charges produced in the path of ionization.

TABLE I

| Critical Gradient Kv. per Cm. | Spark Length by Fig. 2, Cm. | Spark Length Schumann, Cm. |
|---|---|---|
| 30 | 2.02 | 1.9 |
| 35 | 0.89 | 0.47 |
| 40 | 0.48 | 0.19 |
| 45 | 0.39 | 0.09 |

### THE SPACE CHARGE EFFECT

As the initiating electron and its numerous progeny move along the path of ionization, they become separated from the positive ions which are also produced, and thus the growing sphere containing the electrons, which was considered in the preceding section, will not contain enough positive ions to neutralize the electrons, but there will be an excess of negative charge in the sphere. This negative charge and the positive charge left along the path will produce a field, which it is easy to see will increase the electric gradient acting on the more advanced electrons, and decrease the gradient on the lagging electrons. This space charge effect is readily calculable, at least approximately.

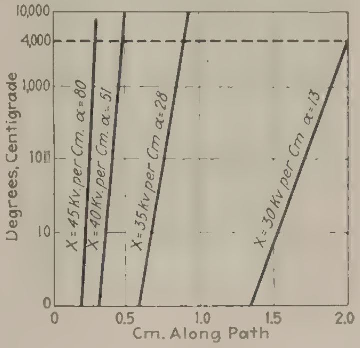

*Fig. 2—Temperature rise in the path of ionizing electron with space charge not considered*

Because of the low mobility of the positive ions relative to that of the electrons, we may neglect the motion of the former and assume that they stand still in space where they were formed. We now calculate the position of the center of gravity, $x$, of these positive ions at the moment the center of the sphere of electrons has reached the point $x$.

The number of positive ions, $dN_+$ generated when the sphere of electrons moves a distance $dx$ is given by:

$$dN_x = N\alpha dx \qquad (13)$$

The mean $x$ co-ordinate of the positive ions will, therefore, be:

$$\bar{x} = \frac{1}{N}\int_0^N x\,dN_+ = \frac{1}{N}\int_0^x \alpha x N\,dx \qquad (14)$$

Substituting $N = \varepsilon^{\alpha x}$ from (5) and carrying out the integration,

$$\Delta x = x - \bar{x} = \frac{1}{\alpha}\left(1 - \varepsilon^{-\alpha x}\right) \qquad (15)$$

The field produced by the electrons at the point $x + R$, will be $\frac{Ne}{R^2}$ e.s.u., and that produced by the positive ions will be $\frac{Ne}{(R + \Delta x)^2}$. Hence, the increase in gradient at the head of the ionizing column due to space charge will be:

$$\Delta X = \frac{Ne}{R^2} - \frac{Ne}{(R + \Delta x)^2} = \varepsilon^{\alpha x} e \left[\frac{1}{R^2} - \frac{1}{(R + \Delta x)^2}\right] \quad (16)$$

$R$ being given by equation (9) and $\Delta x$ by (15). Fig. 3 gives the gradient at the head of the ionizing column for a number of initial gradients.

The space charge effect only changes by a small amount the average gradient acting on the electrons. It increases the force on some, with an almost corresponding decrease in the force on others. But because the rate of increase of $\alpha$ with $X$ is such a rapidly increasing function of $X$ as shown in Fig. 1, it follows that the increase in $\alpha$ for those electrons in the stronger field far exceeds the decrease in $\alpha$ for those electrons in the weaker field, so that the effect of the space charge is to cause an increase in the average value of $\alpha$ for the electrons. Hence, when the space charge effect begins to appear, the effective value of $\alpha$ increases, which causes the space charge effect to increase still more rapidly, so that taking this into account, the curves giving the gradient at the head of the ionizing column will turn up even more rapidly than do those shown in Fig. 3.

*Suppressed discharge on spheres as observed by Torok*

The rapid increase in the value for $\alpha$ at the head of the ionizing column will cause thermal ionization to set in almost at once at the point where the gradient due to space charge turns up rapidly. If again we tentatively assume that breakdown occurs when thermal ionization begins, and locate the beginning of thermal ionization as the points where the curves of Fig. 3 turn up rapidly, we get the data of Table II. The agreement with the values of Schumann is now much better than in Table I.

The electric field due to the space charge is directed radially outward in the sphere of advancing electrons. Hence, it will act like the diffusion in causing the sphere to grow in size. We must compare this effect with the normal rate of growth of the sphere by diffusion to see if the calculations must be altered on this account. From equation (7) we get for the rate of increase in the radius of the sphere due to diffusion,

$$\frac{dR}{dt} = \frac{5D}{R} \quad (17)$$

On the other hand, we may use equation (8) for determining the rate of increase of the radius of the sphere due to the radial field arising from space charge. At the points selected in Table II we get the results shown in Table III.

TABLE II

| Critical Gradient Kv. per Cm. | Spark Length by Fig. 3, Cm. | Spark Length Schumann, Cm. |
|---|---|---|
| 30 | 1.1 | 1.9 |
| 35 | 0.45 | 0.47 |
| 40 | 0.20 | 0.19 |
| 45 | 0.13 | 0.09 |

TABLE III

| Critical Gradient, Kv./Cm. | Radius of Electron Sphere, Cm. | Radial Velocity Due to Diffusion, Cm./Sec. | Radial Field Due to Space Charge, Kv./Cm. | Radial Velocity Due to Radial Field, Cm./Sec. |
|---|---|---|---|---|
| 30 | $7.2 \times 10^{-3}$ | $1.44 \times 10^{6}$ | 4.0 | $16.0 \times 10^{6}$ |
| 35 | $4.4 \times 10^{-3}$ | $2.35 \times 10^{6}$ | 2.2 | $11.8 \times 10^{6}$ |
| 40 | $2.9 \times 10^{-3}$ | $3.56 \times 10^{6}$ | 0.45 | $5.3 \times 10^{6}$ |
| 45 | $2.2 \times 10^{-3}$ | $4.7 \times 10^{6}$ | 0.88 | $7.5 \times 10^{6}$ |

We see, then, that at the points selected in Table II the rate of increase in the radius of the sphere of electrons due to space charge field is greater than the rate of increase due to diffusion; for the 30-kv./cm. gradient it is more than eleven times greater, while for the 45-kv./cm. gradient it is only 1.6 times greater. It must be noted, however, that the effect of the space charge field has only just come into being at the points chosen, whereas the diffusion has been active over the whole path. Hence, the space charge effect cannot have caused the radius of the sphere to have increased much except possibly for the 30-kv./cm. gradient. This calls for a correction which would improve the agreement in Table II.

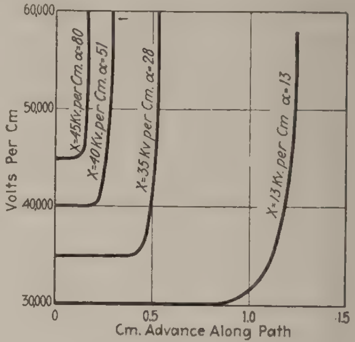

*Fig. 3—Voltage gradient at the head of the ionizing column*

## The Mechanism of Breakdown

We may now consider in more detail the mechanism of breakdown. After the initiating electron has traveled a greater or lesser distance, depending on the gradient as in Table II, the breakdown path becomes thermally ionized. From this point on the initiating electron and its accompanying progeny leave behind them a trail not merely of comparatively immovable positive ions but a trail having a considerable number of free electrons produced during and after the passage of the initiating electron as a consequence of the high temperature of the gas. This thermally ionized trail may be regarded as highly conducting and its influence upon the electric field may be determined from the elementary principle of electrostatics.

At the point where thermal ionization begins we may regard the thermally ionized region as a conducting sphere, and hence the electric gradient at its front and rear will be three times the mean gradient.

As the thermally ionized trail lengthens we may regard it as a rod-shaped conductor in the electrostatic field. The gradient at its ends is then enormously larger than the average gradient; the rate at which it lengthens toward the anode is increased enormously also. At the cathode end of the thermally ionized trail the positive ions move toward the cathode in an intensified field, so that their velocity is much greater than that corresponding to the uniform field, Because of their large number, they also thermally ionize the region they pass over, so that the thermally ionized trail is extended toward the cathode. The charging currents flowing to the sides of the ionized trail will serve to keep the trail thermally ionized while it is extending. When the thermally ionized trail reaches from cathode to anode the sparkover may be said to be completed.

### TIME FOR BREAKDOWN

The theory just developed gives much shorter times for the breakdown process than does the classical Townsend theory. At a gradient just sufficient for breakdown an electron starting at the cathode will cause thermal ionization to appear near the anode. The gradient on the cathode side of the thermally ionized region will be multiplied by three or more, and then as the thermally ionized path extends toward the cathode the gradient will increase to a much greater degree. Positive ions need to move from the neighborhood of the anode clear up to the cathode, as in Rogowski's analysis of the Townsend mechanism, but they now move in a very much stronger field, and also they need to traverse the spark gap space only once for the breakdown to be complete. When gradients larger than that just sufficient to cause breakdown are applied the thermal ionization sets in much closer to the cathode, the positive ions at the cathode end of the thermally ionized trail need to move a shorter distance to reach the cathode and are driven by a stronger field, so that the time is greatly reduced by a slight overvoltage.

In order to calculate the time of breakdown it is necessary to know the radius of curvature of the ends of the rod-shaped thermally ionized trail, so that the electric gradient there may be determined. When thermal ionization first sets in the circular section of the trail by Table III has a diameter of the order of 0.001 to 0.01 cm. After thermal ionization, however, it seems a hopeless task to predetermine the trail section. The pictures of Torok indicate, however, that the trail remains fine, with section probably less than 1 mm. diameter.

If we assume, then, that the radius of curvature of the trail ends is constant and equal to 0.05 cm. we may hope to get results which are correct as to order of magnitude. The calculations for a few cases follow: Consider a 2-cm. gap, for which, according to Schumann, 30 kv./cm. is only a little greater than the breakdown gradient. By equation (8) an electron will move in this field with a velocity of $4.37 \times 10^7$ cm./seconds and will require $4.56 \times 10^{-8}$ seconds to go from cathode to anode. There it produces thermal ionization, and the gradient for the positive ions moving toward the cathode from this region will be 3 × 30 or 90 kv./cm. Using the same formula as was used in obtaining equation (8) we find for the velocity of the positive ion, molecular weight 28.

$$U_{\infty} = 5.6 \times 10^2 \overline{X^{\frac{1}{2}}} \qquad (18)$$

The initial velocity of the positive ions will, therefore, be $3.36 \times 10^5$ cm./seconds.

To calculate further, we need to know the radius of curvature of the cathode end of the thermally ionized trail, and we assume it to be 0.05 cm. Let us then take as an approximation to the field intensity at the end of the trail that intensity which would exist at the surface of a 1-mm. diameter conducting sphere, placed at the end of the trail, and joined by a wire to the anode. We then get, letting $y$ be the distance to the anode, $X$, the mean gradient, and $\overline{X}$ the gradient at the sphere surface,

Hence
$$\overline{X} = (20y + 1)X \qquad (19)$$

$$v_+ = \frac{dy}{dt} = 5.6 \times 10^2 \overline{X}^{\frac{1}{2}} = 5.6 \times 10^2 (20y + 1)^{\frac{1}{2}} X^{\frac{1}{2}} \qquad (20)$$

Using this equation, the time to reach the cathode is approximately:

$$t = \frac{4.46 \times 10^{-4}}{X^{\frac{1}{2}}} \int_{y_o}^{2} \frac{dy}{(20y + 1)^{\frac{1}{2}}} = \frac{4.46 \times 10^{-4}}{X^{\frac{1}{2}}} \left[ 0.64 - 0.1(20y_o + 1)^{\frac{1}{2}} \right] \qquad (21)$$

Taking $X = 30{,}000$, and $y_o = 0.1$; i.e., the value for which $\overline{X} = 3X$ by (19) we get

$$t = 4.2 \times 10^{-6} \text{ seconds}$$

The total time of breakdown is, therefore, $4.2 \times 10^{-6} + 4.56 \times 10^{-8} = 4.2 \times 10^{-6}$ seconds.

Let us now consider the 2-cm. gap with a gradient of 35 kv./cm. By Table II, thermal ionization begins at 0.45 cm. from the cathode, or 1.55 cm. from the anode. Hence setting $y_o = 1.55$ and $X = 35{,}000$ in (21) we get

$$t = 7.4 \times 10^{-7} \text{ seconds.}$$

For a 40-kv./cm. gradient we have by Table II $y_o = 1.8$, and by (21) we get

$$t = 2.6 \times 10^{-7} \text{ seconds.}$$

For a 45-kv./cm. gradient we get $y_o = 1.87$ and

$$t = 1.7 \times 10^{-7} \text{ seconds.}$$

The times for breakdown thus calculated agree well in order of magnitude with those obtained by experiment, and the rapid increase in breakdown speed with moderate increase in overvoltage also comes out very satisfactorily.

---

## Bundling Cable Reel Lagging

By N. E. BUCK
*Superintendent of Underground Work*
*Commonwealth Edison Company, Chicago, Ill.*

THE handling of lagging removed from cable reels is always a problem. If the pieces are piled loosely around the reel they are a hazard to pedestrians and workmen and are easily removed for bonfires by the omnipresent small boy. The Commonwealth Edison Company formerly bundled the lagging with No. 8 iron pull wire, but the wire could not be pulled up tight enough to prevent the inner pieces from sliding out when the bundles were handled and a loose piece of wood of this size involves safety hazards. One of the men in the underground department worked out a scheme for using galvanized steel strip which was pulled tightly around

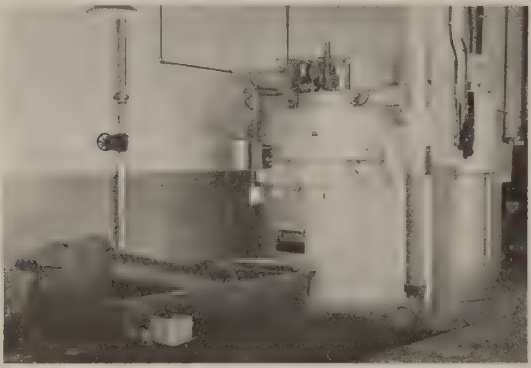
*Reel lagging readily bundled with galvanized strip* the bundle by means of a special tool and then nailed down. This method has proved to be far superior to any heretofore used. It is safe and easy and it greatly facilitates piling the lagging in the yard during storage and preparatory to its ultimate disposal.

## Rotary-Hearth Furnace for Small Pieces

By W. J. Diederichs
*Industrial Heating Engineer*
*Westinghouse Electric & Manufacturing Company*

An automatic discharging device incorporated in an electric furnace of rotary-hearth type permits the hardening of cap screws and similar parts with satisfactory operating economies. None of the parts is larger than $\frac{1}{2}$ in. in diameter by $3\frac{1}{2}$ in. long. They are treated in quantities of 800 lb. per hour. The material is heated to 1,500 deg. F., properly soaked and then discharged for quenching purposes.

The furnace provides an annular heating chamber 24 in. wide by 23 in. high, the floor of which consists of a rotating hearth of 5 ft. mean diameter, upon which twelve alloy trays are mounted on trunnions, about which they rotate when the rear end is lifted. The slope of the tray, when so lifted, is sufficient to discharge any work. The hearth is motor driven and is normally stationary. The control of this drive is such, however, that at regular intervals the hearth is advanced one tray and again stops. When in any of its stationary positions the hearth spots one tray directly in front of the charging door and another tray directly over a discharge chute. The time which the hearth remains stationary is adjustable and by this means the time the work remains in the furnace, subjected to heat, can be varied through wide limits. This permits the adjustment of the heating cycle to the size of work to be treated.



*Small-parts treating furnace employs automatic discharging device*

The automatic discharge mechanism is mounted on top of the furnace. It is motor driven and electrically interlocked with the hearth drive. Immediately after the hearth has stopped with a tray over the discharge chute the discharge motor engages with a hooked arm which extends through the furnace roof and connects under the tray. The hook, on being lifted, raises the tray and discharges the work into the discharge chute, whereupon the hook and tray are automatically lowered to their original stationary positions.

At regular intervals a tray of properly heated work is automatically "dumped" into the discharge chute and quenched. In traversing the chute and falling through the quenching medium the individual pieces are separated so that quenching results are obtained which closely approximate those obtained by the ideal individual quenching.

The furnace has an electrical input of 90 kw. for operation on 230-volt, three-phase power supply. This input is divided into two zones, each occupying one-half of the annular chamber. Each zone is independently controlled by a separate pryometer and thermocouple actuating suitable contactor panels. This two-zone arrangement of input permits adjusting the temperature being maintained in the ingoing and outgoing halves of the chamber and makes it possible to vary the rate of heating of the work.

The furnace, when operating at a production of 800 lb. of work per hour at a temperature of 1,500 deg. F., successfully treats 9 lb. of work per kilowatt-hour of energy consumed.

## "Activity" of Lamp Sockets in Residential Field

By M. Luckiesh
*Director Lighting Research Laboratory, National Lamp Works of General Electric Company*

From two extensive surveys of homes in all parts of this country and from other observations we find that the average home, exclusive of halls, closets, basement and exterior, consists of 6.5 rooms, of which 2.5 rooms are bedrooms. In this average home there are 22 lamp sockets, distributed as follows:

| | Sockets | | Sockets |
|---|---|---|---|
| Living room | 6.0 | Bathroom | 1.3 |
| Dining room | 3.7 | Basement | 2.1 |
| Kitchen | 1.4 | Halls | 1.7 |
| Bedrooms (2.5) | 5.8 | | |
| | | Total | 22.0 |

For purposes of computation and discussion we have coined the terms "average socket" and "active socket." The average operation per day per socket for lighting amounts to approximately one hour. Therefore, we have defined an "average socket" as one which operates an average of one hour per day, or 1,000 hours (one lamp-life) in three years. However, there are certain sockets in the house, such as that in the modern kitchen unit, which we term "active sockets." An "active socket" is defined as one which operates 1,000 hours per year, or approximately three hours per day.

One "active socket" containing a 50-watt lamp represents to the central station at the present time an increase of 16.5 per cent in gross lighting revenue per customer and an increase of $3.82 in annual gross revenue per customer. According to some figures which we have this represents an increase of 150 per cent in annual net revenue.

The average home today requires about seven lamp renewals per year, which accounts for the sale of 123,000,000 lamps per year. For each million new homes added to central-station service each year at least 22,000,000 lamps are installed. If we include the sockets in halls, closets, basement and exterior this figure becomes at least 27,000,000. Thus we may account for 150,000,000 large lamps entering the homes of this country each year.

# Off-Peak Rate Desirable

New England utility attracts valuable ice-making load through adjusted rate base. Customers minimize demand during restricted periods

By J. A. Cook

*Superintendent Electrical Department,*
*Lynn (Mass.) Gas & Electric Company*

ICE-MAKING plants have requested a number of public utility companies to develop suitable power rates for this kind of business. In some cases it has been difficult to convince the utilities of the value of the load and the importance of making rates competitive with other kinds of drives, including Diesel engines. Still, considerable progress is being made with purchased-power installations where the estimated cost of electric power is close to that of mechanical drive. In these instances the small investment required for the electrical equipment and the simplification of operating problems and maintenance has turned the scales in favor of electricity.

To the central station this business has the advantages of being off-peak and having a high power factor and weekly load factor. The Lynn company recently studied the situation and has developed a profitable rate based on the attractive features of the load.

In examining others' rates it was found that the New York Edison, United Electric Light & Power and affiliated companies have a schedule based on weekly bills figured from the weekly maximum kilowatt demand, which in well-managed ice plants is nearly the same as the weekly average demand. From November to February, inclusive, shutdown of major apparatus is required between 4 and 8 p.m. The demand charge is adjusted yearly according to annual revenue. Using this rate as a base, it was modified for Lynn to insure that all load occurring on the peak is paid for in full, including energy and investment costs, and that the best rate is earned by large consumption at high weekly load factors. Annual adjustments involving large refunds or excess payments which might disturb the customer's cash position are avoided by the terms adopted. Energy is taken at unity power factor whenever possible; normally it runs between 95 per cent lagging and 95 per cent leading.

### Essentials of Lynn Rate

Available to customers with 200-hp. minimum connected load, ice making only, with synchronous motor drive, capable of operating at leading power factor for main compressor units to keep between 95 per cent leading and 95 per cent lagging.

Customer supplies and maintains transformers and supplies ventilated transformer vault or approved outdoor platform and also space for metering equipment and service oil circuit breaker.

Energy may be used for lighting ice manufacture not exceeding 5 per cent of the total kilowatt-hour consumption of the ice plant.

Power demand restricted 4 to 8 p.m., November-February inclusive, to 10 per cent of highest demand during preceding twelve months.

All energy used off-peak billed weekly at:

| Energy Billed per Calendar Year (Net) Kw.-Hr. | Bill per Week per Kilowatt Demand |
|---|---|
| First 7,500 | $2.14 |
| Next 7,500 | 1.99 |
| Next 7,500 | 1.84 |
| Over 22,500 | 1.70 |

All energy used during the restricted period is billed for each of ten consecutive weeks beginning with the time of use at $4.50 per kilowatt per week of such demand. The total charges for energy used during the restricted period amount to $45 per kilowatt of maximum demand during that period.

Kilowatts of demand are measured over fifteen-minute time

*Computation of Customer's Bills for a Year's Period Under Assumed One Year's Operation of 140-Ton Plant in New England*

Natural Ice Used to Some Extent During Winter Months

| | Off-Peak Period | | | | | | Restricted Period | | | Total Bill | | |

| Sept. 1 | 300 | 0.93 | 24 | 46,872 | 1.84 | 552.00 | .. | .... | ... | 552.00 | 496.80 | 15,332.50 |
| Oct. 5 | 200 | 0.93 | 24 | 156,240 | 1.84 | 1,840.00 | .. | .... | ... | 1,840.00 | 1,656.00 | 16,988.50 |
| Nov. 4 | 150 | 0.93 | 20 | 78,120 | 1.84 | 1,104.00 | 20 | 1,344 | 360 | 1,464.00 | 1,317.60 | 18,306.10 |
| Dec. 5 | 100 | 0.93 | 20 | 65,100 | 1.84 | 920.00 | 20 | 1,680 | 450 | 1,370.00 | 1,233.00 | 19,539.10 |
| Totals 52 | | | | 1,578,024 | | $20,799.00 | | 3,360 | $900 | $21,699 00 | $19,539.10 | $19,539.10 |

Average rate per kilowatt-hour over year = $19,539.10 ÷ 1,581,384 kilowatt-hour = $0.01235 per kilowatt-hour.

intervals. The maximum demand in each week is used for that week's billing.

Discount of 10 per cent of total bill if paid within five days of date of bill.

Minimum charge, $7,500 per year, excluding coal clause and charges for energy used in restricted period.

Coal Clause—For each 25 cents increase or decrease in the price of coal per gross ton at company's bunkers from the base price of $5.35 per gross ton, the net price of energy is similarly increased or decreased 0.02 cents per kilowatt-hour.

### RATE APPLIED TO 140-TON PLANT

The equipment required by a 140-ton plant now being installed to operate under the above rate consists of the following synchronous motors: One 175-hp., 20 per cent leading power-factor synchronous, driving No. 1 main compressor, and one similar 100-hp. motor driving No. 2 main compressor; one 30-hp. induction motor for air compressor (one air compressor is driven by a gasoline engine), and the following other induction motors: Two 7.5-hp. for agitators, three 4-hp. for bridge type crane, one 1-hp. for core siphoning unit, two 7.5-hp. motors for water pumps, one 1-hp. for brine pump, one 3-hp. for auxiliary air compressor, one 2-hp. for ice tiering machine, two 10-hp. motors for motor-generator exciter sets and one 2-hp. motor for ice conveyor. This gives a total of 275 hp. in leading power-factor synchronous motors and 101 hp. in inductions. Although the main compressors are shut down during the restricted period, certain other motors have to run. Thus, the agitator motors must operate or the ice in the tanks will freeze white. The brine continues to circulate and some ice is made while the main compressors are shut off. It appears that for the above plant efficient operation can be had during the restricted period with a demand of 15 kw. At full capacity the demand may reach 350 kw. There are 480 hours in the period of restriction, and each kilowatt of the maximum demand during this period is billed at $40.50 net. Thus the customer pays in full for all use of capacity during the restricted period, including investment charges on generating station, transmission and distribution equipment, as well as for energy used. It is to the customer's advantage to keep his maximum demand at a minimum during this period.

Ice plants can readily operate for a week at load factors between 90 and 95 per cent figured on the unrestricted period; i.e., 24 hours per day during eight months and twenty hours per day during four months. The total annual unrestricted period is 8,280 hours. Each week the ice manufacturer determines the running rate for the entire week and adjusts his operation to that rate. He is free to adjust to a new rate of manufacture at the start of the next week. During the winter months in New England some use will be made of natural ice, and the total volume of business is less than in summer. The ice manufacturer may shut down his plant for several weeks during the winter and in general will have a smaller power demand in winter. The accompanying table shows how the rate applies during a typical year for a typical 140-ton plant operating under expected schedule.

This table and the rate schedule show that the rate paid per kilowatt-hour increases as the load factor decreases. In other words, the ice manufacturer has the opportunity of earning a lower rate by operating at higher load factor. The rate "puts it up to him," as he pays according to his demand, but is free to use his maximum demand during the entire unrestricted period.

Synchronous motors with 20 per cent leading power-factor design are installed on the main compressors. This permits maintaining unity power factor on the entire plant. A graphic power-factor meter is installed to verify customer's adherence to the unity power-factor requirement.

The accompanying tabulation shows that during a calendar year the customer pays his weekly bills without heavy adjustments. This is accomplished for the unrestricted period by adopting a step rate for kilowatt demand. He pays the highest step of the rate commencing with Jan. 1 of each calendar year until his weekly payment to the company totals $7,500, when he is billed on the next lower step of the rate until his payments have totaled $15,000. The next lower step then becomes effective. The tabulation shows the figures for a 140-ton plant. A 200-ton plant gets the benefit of the last step in the rate and accordingly earns an appreciably lower rate per kilowatt-hour.

Our own executives regard this business as most attractive for the utility company, as it gives a steady load during all hours except the annual peak periods. The high load factor and high power factor are particularly helpful in reducing switchboard costs during the early morning hours when residence load and factory load have dropped to a small fraction of their maximum value. The ice manufacturing load comes on the valleys of the central station daily load curve and tends to lower the unit cost of all energy delivered to the generating station busbars. The ice-making load is a maximum during the summer when the central station output is relatively small.

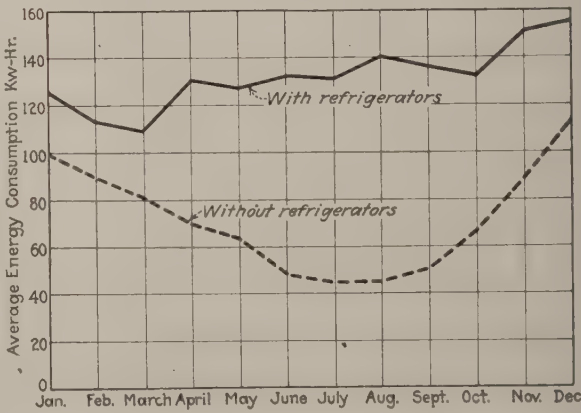
---

# Refrigerators Reduce Fluctuations of Domestic Consumption

By E. H. JENNESS
*Power Sales Engineer Ohio Public Service Company, Elyria, Ohio*

AN ANALYSIS by the Ohio Public Service Company of the energy consumption of eighteen domestic consumers in Elyria, Ohio, indicates the value of electric refrigeration as an equalizing influence upon load fluctuations throughout the year. The survey covers approximately 4 per cent of the total domestic refrigeration list.

These users of electrical service were somewhat above the general average of residence consumers even before



*Average summer energy consumption raised by refrigerator load*

Electric refrigerators were installed in the spring of 1926 in the homes of eighteen utility customers whose average monthly consumption throughout two consecutive years is indicated.

they installed electric refrigeration. Furthermore, the total increase shown by the curves cannot be attributed entirely to the installation of refrigeration units, as all of the domestic customers demonstrated a normal increase in energy use from 10 to 20 per cent. The results do, however, indicate clearly the possibility of summer load factor improvement for the generating station through increased use of refrigerators.

## Analyzing a Street-Lighting Contract

RECENTLY an Eastern power company and the principal city it serves carried on negotiations for a street-lighting contract over a period of many months without coming to an agreement until an arbitration board determined the terms. In the course of the proceedings a consulting engineer for the city presented a draft of a new contract which contained many features objectionable to the company in comparison with the terms of its own proposal. In the belief that some of the principal features of the city's proposal which were found to be undesirable by the company should be known to other utilities carrying on similar negotiations, an outline of typical points discussed analytically by the company before the arbitration tribunal follows:

### Relation Between Rates and Term

Lower prices are the natural result of security of a long term. If the term is short, e.g., a few months or one or two years, the company has no assurance that at its expiration the city will not materially reduce the number of lamps required, rearrange their location, or require the substitution of an entirely different type of lamp. Should the action of the city be arbitrary or capricious, it would entail the scrapping of costly apparatus and equipment long before worn out, thus putting a heavy burden on the company. Again, controversial negotiations are damaging in the public mind and cause economic loss by disrupting the attention of employees from normal duties.

### Points Not Made Clear in City's Proposal

Both parties have agreed to no further extension of the magnetite system, but the city's draft makes no recognition of this.

It should be made clear that the contract remains in force after expiration unless and until notice of termination is given by one party to the other.

Sixty days' notice is too short a time to negotiate a new contract.

Lamps are described in wattages only; both watts and candlepower should be stated.

The location and method of lamp installation should be included with stated price, rating and number of units.

### Specification of Payment

Contract clause should make it clear that the city should pay for service on the next regular pay-day following rendition of monthly bills by the company. Agreement should contain clause that the liability of the city thereunder is made subject to the making of sufficient appropriations from time to time to carry out the contract provisions.

### Quality of Service

The city's draft carries unreasonable penalties for outages and the use of such terms as "maximum of good service" and "maximum of unobstructed light" is too rigid for practical application and might lead to disputes. No equipment can be maintained at its "maximum," and the company should only obligate itself to give satisfactory service.

### Miscellaneous Objections

The company should be able to make independent contracts for street lighting in adjoining or adjacent municipalities without becoming involved in a dispute with the city.

The company should not be obliged to assume the initial expense of defending all suits and proving the city's negligence.

Testing equipment should conform to a specified standard and the interval between tests should not be inconveniently short.

The company should not be under the obligation to pay for all extensions.

The proposed agreement permits the city arbitrarily to reduce the number of lamps and to continue indefinitely on such a course. The city has the objectionable right to nullify the contract at any time, which would render the agreement of small value as such from the company standpoint. Again, the city has the power to order an extension of the hours of burning without statement of the company's right to make an additional charge for such service. The terms "extra dark mornings and evenings" are too elastic.

Inspection requirements are excessive and the clause requiring the company to favor residents of the city in taking on employees discriminates against residents of suburban towns which it serves.

Individuals and boards not conversant with or trained in technical matters are given undesirable power to specify the kind of equipment which shall be operated by the company in street lighting.

## Modern Electric Deliveries

A FLEET of six electric vehicles of smart appearance, rapid speed and long-mileage characteristics has recently been placed in service by Bonwit, Teller & Company, a New York department store. The appearance is entirely that of a modern gasoline vehicle. Speed, 18 miles an hour. Service, 70 miles at one charge. Body capacity, 100 cu.ft. The bodies were built by the Elysee Corporation, the chassis by the Walker Vehicle Company.

## Electric Baking of Food Products Proves Economical

A LITTLE more than two years ago the Tasty Baking Company, Philadelphia, was operating all of its power and lighting load with a current consumption of 55,000 kw.-hr. per month. At that time, according to R. M. Gantert of the Philadelphia Electric Company, the only increase in business which could be expected was that which would result from normal growth of the power load. Today, however, this bakery is consuming about 395,000 kw.-hr. per month, representing an increase of 600 per cent in current consumption and about 325 per cent increase in revenue from this customer. The utilization of energy will be increased by about 100,000 kw.-hr. within a short time. This remarkable increase is the result of the application of electricity in the baking of various types of food products in this plant. The first oven to be installed was a 70-ft. one with a connected load of about 325 kw., operating at temperatures between 300 and 400 deg. F. According to Mr. Gantert, this oven was a complete success from the start, baking a cake of better quality with less spoilage and proving to be more economical than estimated. "When properly analyzed, the current cost chargeable to the oven is such that, with all factors considered, the resultant cost is lower than any other known method of baking."

It is estimated by Mr. Gantert that the fuel costs of

## Organize to Build Load of Existing Rural Lines

"WHENEVER we get ready to handle a major operation or to do anything new which calls for expenditure of a great deal of money and adds materially to the property and income of a company, the first thing we do is create an organization to handle the new work. The bigger the job the bigger the organization and the higher grade man we select to head it up. It seems to me that inasmuch as the rural development is a new development, a big development and an important development, we must certainly be willing to organize fully and carefully to bring it about efficiently and rapidly. This calls for the proper organization of a rural-service department in any utility company operating in rural territory.

"Our first job is to build up the load of the farm customers we now have and to secure as customers those farmers now living along or near existing lines, but who for some reason or other have not connected to them."

G. C. Neff,
*Vice-President Wisconsin Power & Light Company.*

baking represent only about 1 per cent of the selling price of a loaf of bread and that even a reasonable increase in a 1 per cent item will be more than offset by intangible advantages. Because of the fact that these ovens operate at unity power factor the system power factor is improved and attractive characteristics are offered to the utility company. According to Mr. Gantert, the 40 large bakeries in the territory served by the Philadelphia Electric Company, which may be considered to be prospects for electric heat for baking purposes, represent a possible load of about 20,000 kw. with an assumed energy consumption of 85,000,000 kw.-hr. a year. This is estimated to represent about $1,000,000 a year possible business from an entirely new source.

## Elimination of Old Ranges Purpose of Campaign

HAVING as its object the elimination of all ranges built prior to 1921, the Southern California Edison Company has under way a campaign which it is hoped will displace 4,000 of the older type ranges on its system with ranges of the latest type. It is realized that one of the greatest obstacles to the sale of the electric range is the presence throughout the country of six- to eight-year-old ranges, with their relatively slow cooking speed and consequent increased operating cost. Central stations have been up against practically the same situation that the automobile manufacturers would have to meet if the bulk of buyers of cars were to use the same automobile for seven or eight years.

The Southern California Edison Company has decided to profit by the experience of automobile dealers and make a generous allowance to owners of these old ranges on the purchase of new ranges. An appropriation has been set aside which it is expected will be sufficient to eliminate practically all of the 4,000 older types of ranges on the Edison system. During the first month of the campaign its effectiveness was proved by the fact that 139 exchange sales were made.

In furthering the campaign the word-of-mouth method is used, no advertising of any kind being brought into play. If results of the campaign are as anticipated, it is expected that this move will have a stimulating effect upon all range sales activities in the territory served.

## Floodlighting Establishes Theater Location

FLOODLIGHTING as a means of advertising is not particularly new, but the floodlighting of an uncompleted building possesses some novelty. A Seattle building corporation decided, after careful study of the city's present development, that a location that is now outside the "white-light" district and eight blocks from the heart of the present retail shopping district would in ten years be in the center of a new section. It was confronted, however, with selling the location to Seattle now and determined to bring the "white-light" district to a theater and apartment building by the use of floodlighting during construction.

*Selling the public a new theater location through use of floodlighting during building construction*

Ten 1,000-watt Pittsburgh floodlights were installed on street railway poles across from the building on one side and six on the other. It was found that the curiosity of night pedestrians, window shoppers and theatergoers led them past the building to see what it was all about. Pedestrian traffic was practically tripled, while vehicular traffic was increased by about one-third. By the time the theater was opened, on March 1, practically every one in Seattle had the location firmly fixed in mind and a relatively inexpensive newspaper campaign was all that was necessary to insure "houses" from the start So successful was the floodlighting advertising campaign during building construction that the installation is to be made permanent.

# Letters from Our Readers

## *Southern Pine and Creosoting*

*To the Editor of the* ELECTRICAL WORLD:

I have read with considerable interest the article on "Southern Pine and Creosoting" in the Feb. 18 and March 3 issues of the ELECTRICAL WORLD and feel that you have contributed valuable data for the readers of your magazine.

The second paragraph of your article in the March 3 issue in regard to the seasoning of timber products before treating impresses me particularly, as in my judgment sufficient consideration is frequently not given this very important feature.

My observations at several of the treating plants revealed the fact that Southern yellow pine piling, poles and timbers are treated when having a very high moisture content, and in fact when only a few days from the stump. In order to secure the desirable penetration of creosote these timber products are subjected to live steam under pressure for several hours, followed by a partial vacuum to remove moisture. Statistics show that the moisture removed in this manner is but slightly more than the amount added by the live steam, and consequently timbers are removed from the treating cylinder with practically the same moisture content as when entering, with the serious disadvantage that wood fibers have been more or less strained by the live steam and that the moisture is forced toward the center of the timber by the pressure treating process.

It is a well-known fact that timbers are weakened in proportion to the increase in moisture content and it is very evident that many of the commercial treating plants, in their endeavor to fill rush orders for treated poles, etc., are supplying their customers with material far below the working stresses allowed for the different species. On the other hand, where an effort has been made to air-season Southern pine I have seen very decided evidence of fungi after four or five months, indicating that in some localities, at least, it is impossible thoroughly to air-season this species of timber without danger of decay to the sapwood.

In my opinion the solution of the problem is in "boiling under vacuum," whereby the moisture is taken from the timber instead of being forced toward the center. The danger of injury to the timber during the boiling process is avoided provided a uniform and constant temperature is maintained throughout the cylinder at a degree suitable for the species under treatment.

I am thoroughly convinced the Southern pine pole will become the standard for the Southern and Eastern territories, but in order to secure the maximum service from them and at the same time obviate the necessity for carrying charges, either by the producer or consumer, I feel that improvements must be made in the present methods of seasoning and treating this material.

THOMAS A. WILSON,
Superintendent Timber Department.
Consolidated Gas, Electric Light & Power Company of Baltimore.

## *Price or Cost?*

*To the Editor of the* ELECTRICAL WORLD:

In a paper of recent date by public-ownership proponents, claims have been asserted that the domestic consumer is the victim of discriminatory rates, while the large power user enjoys low rates made under pressure of competition with private plant operation. The domestic consumer, being unable to produce his own electricity, is forced to accept the rates and is thereby made to pay for losses or small margins of return incurred in serving the larger customers, is the claim of these writers.

On first thought the obvious answer would seem to be available from cost analyses showing the rates of return earned from different classes of customers. The results invariably show that the domestic consumers are less profitable to the utility companies than are the large users.

However, there are other considerations more pertinent and which merit consideration regardless of what results a cost analysis shows. Let us assume that such an analysis will show that the domestic consumers yield a company a larger return than do a number of large industrial plants on its lines. Assume, further, that to remedy this "discrimination" large power rates are raised. The effect of this would be to release some of these larger customers and to discourage the acquisition of additional industrial customers. Even if we discount the expense incident to the capacity of the system released by the loss of these large users there will be a lower load factor, not only in the sense of expenses at the generating station but that concerned with maximum utilization of the property. The effect of this will be to leave a larger burden of fixed charges and expenses to be borne by the residential customers. This will place them in a distinctly less favorable position in the matter of cost of supply, and consequently rates, than were the large users retained at the lower rates under which they now operate.

So it can be seen that discrimination is a difficult charge to sustain if the concern of the domestic consumers is for the lowest rate compatible with a reasonable return and unimpaired service. With this as the only premise on which the champions of domestic rates can proceed, it is obvious that the only ultimate concern of the domestic customers should be: Under what policy can the lowest rates be secured, and not with figures purporting to show unjust discrimination without considering the effect of these competitive rates upon the costs, and consequently upon rates to the domestic consumer.

In substance, then, the claims of unjust discrimination fail to consider the reciprocal effect of price upon cost, but are seemingly content to neglect this mutual interrelationship.

While this discussion is somewhat hypothetical in character, I believe it portrays the futility of attempting to charge discrimination in this question of small versus large consumers. It should be remembered the costs for service are made possible by the contributions of all classes to the system and that the lower unit costs are the fruits of all rather than the property of a single class. In fact, the small consumer should in a measure be thankful to his large manufacturing brethren for the latter's having assumed an important rôle in lowering the charges for service to all classes.

Pelham Manor, N. Y. JOHN F. DUFFY.

# Digest of Electrical Literature

## Hydro-Electric Development and Steam Equipment

*Steam Storage in Power Stations.*—The application of a steam accumulator of the Ruths type is described in this article. A specific application in the generating station of the Malmo municipal power plant in Sweden is cited. In this application two accumulators, each of 8,000-cu.ft. volume and with a joint capacity of 80,000 lb. of steam on a pressure drop of 114 to 28 lb. per square inch, are used with a specially designed condensing steam turbo-generator of 3,750 kw. capacity. It is stated that the accumulator installation is sufficiently large for supplying steam to the turbine for about one hour while developing some 3,000 kw. This is estimated to be sufficient to start the turbine, and as soon as the proper pressure has been obtained from the boilers the turbine is run by steam from that source until the hydraulic power, which is the primary supply of the station, can be applied. As soon as the load is taken over by the hydraulic power and the accumulator is charged to full pressure through the valve, the boilers are shut down.—*Electricity* (*England*), March 15, 1928.

## Transmission, Substations and Distribution

*Cable Laying Improvements.*—E. S. Byng.—In this first of several articles the author has discussed the types of cable systems as a preliminary to the contemplated discussion of actual installation practices. An analysis has been made of the several plans and methods for overhead and underground work used in European countries and the advantages and disadvantages of these methods are compared. Economic considerations involved in determining whether cable should be laid direct or in a duct have been considered by the author. The conduit system has a number of advantages over other methods, including: Minimized trenching operations, minimized paving charges, flexibility of carrying capacity, simplified replacement of impaired sections, simplified repair operations and high reclamation value.—*World Power* (*England*), March, 1928.

*Voltage Regulation.*—The merits of various types of regulators have been summarized as follows: Induction regulators avoid interruption of circuits on switch contacts and give smooth regulation, internal regulators on tapped transformers concentrate the whole apparatus into a small space and minimize external connections, the separation of the switchgear simplifies transfromers and reduces their over-all dimensions with particular advantage in the largest units, natural cooling of transformers is unrestricted and removal from tank is facilitated, there are no moving parts in the transformer tank and the makers claim that the design of the regulating switch is not hampered by the necessity of adapting it to transformer, routine inspection is possible without opening up main transformer, and, in those cases in which it is practicable to provide suitable isolating gear, inspection is possible without cutting off the supply. A description is offered of the so-called Brookhirst drum type regulator, which comprises for each phase a drum type tapping selector switch not subject to arcing and one which needs no adjustment throughout a reasonable life. This provides two independent circuits necessary to permit changing over without interruption to the main circuit and, if required, reverses the regular winding. The regulator is composed of two drum type, quick-break diverter or auxiliary switches, with renewable butt contacts especially designed for circuit breaking. Continuity of the main circuit is assured either by self-contained buffer resistances or separate intermittently rated choking coils. Mechanical operation, in correct sequence, of the auxiliary switches by cams and of the drum by smooth-action intermittent gear insures the interruption of each circuit on its auxiliary switch before the drum moves, and the drum construction prevents the possibility of wrong connections.—*World Power* (*England*), March, 1928.

*Methods of Determining Correctness of Watt-Hour Meter Connections.*—The necessity for a simple, accurate and complete method for checking the connections of polyphase watt-hour meters in service has been recognized by the engineering and statistical subcommittee of the meter committee of the N.E.L.A. in the preparation of this report. A new scheme for checking the correctness of connections with watt-hour meters used with instrument transformers is described. It is stated that no method as yet advanced will cover all possible incorrect connections in cases where the power-factor angle of the load cannot be ascertained within 60 deg. of its actual value. It is stated, however, that the new method described in this report constitutes a real contribution to the information available on this subject. In addition, a check may be made under normal operating conditions by any meter tester familiar with alternating-current meters and circuits. The report covers the methods of making connection on two-element, three-phase watt-hour meters connected to three-wire, three-phase primaries through instrument transformers. A theoretical analysis of the general problem of checking the correctness of connection, a description of the new method and a discussion of the schemes for checking the connections which have been proposed in the past, together with an indication of the limitations of each scheme, is offered.—*Serial Report, National Electric Light Association,* March, 1928.

## Units, Measurements and Instruments

*The Dufour Cathode-Ray Oscillograph.*—I. E. Cole.—The design and application of the Dufour cathode-ray oscillograph has been outlined by the author. It is stated that many different techniques have been developed for using this instrument, each particularly suited to some special investigation. The author has outlined several characteristic procedures.—*Sibley Journal of Engineering,* March, 1928.

*Statical Hysteresis in Cycles of Equal Load Range.*—G. H. Keulegan.—The author has endeavored to ascertain the influence of the extreme loads on the energy hysteresis loss in the cycles of equal load range during the flexure of an iron bar. The flexure of the bar is considered for the case where one end is clamped and the other end loaded. Armco iron was used and since the hereditary hysteresis of this material is negligible in comparison with the statical hysteresis the results of the experiment apply mainly to the latter. Cycles of small extreme loads only are considered and the conclusion derived from the result of the experiments is to the effect that the energy loss due to statical hysteresis in cycles of equal load range is independent of the extreme loads. The apparatus used in this investigation and the experimental procedure, as well as an analysis of the specimen and a thorough discussion of the data secured, are offered. The value of the hysteresis modulus of Armco iron was predetermined and found to be in agreement with the results of previous experiments.—*No. 365 Technologic Papers of the Bureau of Standards.*

## Illumination

*Methods of Calculating General Illumination Intensities for Interiors.*—Imbrie Smith.—The author has endeavored to cover in a comprehensive way the various developments and methods used in estimating illumination intensities and values in interior work. The polar curve of light distribution, the law of inverse squares and the cosine law are recognized as the fundamental basis for such calculations. Because of a number of technical difficulties involved in the application of these fundamentally desirable values, a number of emperical formulas have been evolved, and in this first of several articles the author has considered the value and use of such devices. This discussion constitutes not only historical record of progress in illuminating engineering but also involves the practical features of design and estimating work. —*Illuminating Engineer (England)*, March, 1928.

### *Traction*

*Heavy Electric Traction in Italy.*—THEODORE RICH.—Electrification has proceeded to a state of wide utilization in Italy. The author has endeavored to review the factors which influenced the change-over from steam to electric equipment throughout this country and has analyzed the factors involved in the power supply, application and utilization of equipment in this first of several articles. An unusual feature of the design is the inclusion of two trolley wires, made necessary by the utilization of three-phase power on the locomotive. Each locomotive has two sets of contact bows for pick-up purposes.—*Electrical Review (England)*, March 23, 1928.

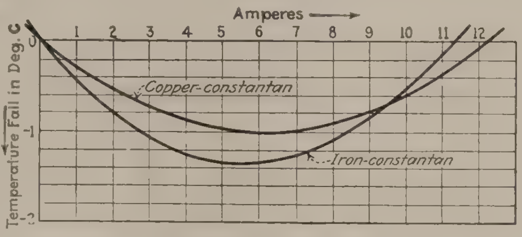
*Railway Electrification.*—E. H. CROFT.—A comprehensive review of the general methods in vogue for the protection of electric railway equipment with suggestions for various improvements for the minimization of danger and the avoidance of delays. The author suggests that the arrangement of protection devices should be such that the main power circuits and the auxiliary power circuits should be kept separate as far as possible; that apart from ordinary overload relays and auxiliary circuit fuses additional protection should be afforded to both circuits in the form of some type of protective apparatus close to the supply of energy on a car; the circuits should be so arranged that either the protective apparatus should not be called upon to interrupt a circuit showing a greater current than the capacity of the device allows for, so that the interrupting of such current should be transferred to the protective apparatus capable of handling it, and that it should be realized on low-voltage systems that it is difficult to transfer the faults to the feeder or substation breakers and that therefore the protection of low-voltage systems is more difficult than that of high-voltage ones.—*Electrical Review (England)*, March 16, 1928.

### *Telegraphy, Telephony, Radio and Signals*

*Radio-Controlled Motor Boat.*—M. CHAUVEAU.—A high-speed motor boat, driven by two 180-hp. gasoline motors, which is so equipped that all maneuvers can be controlled by proper radio impulses from the shore, is described. The arrangement of the control relays for the starting and accelerating or reversing of the motor, the setting of the rudder and the lighting of a searchlight at the bow of the ship is also outlined. An 80-volt, 40-amp.-hour storage battery serves to supply the necessary control current on the boat. This battery is charged from a 500-watt generator, driven by one of the gasoline motors. The radio control is accomplished by a sustained 300-meter fundamental wave, modulated by 30,000-cycle high-frequency impulses. Great care was taken to make the controls absolutely unaffected by static, commercial code or radio programs. —*Bulletin de la Société Française des Electriciens*, December, 1927.

### *Electrophysics, Electrochemistry and Batteries*

*The Peltier Effect.*—T. F. WALL.—Closely allied with the generation of electromotive force by heating or cooling a junction of two dissimilar metals is the reverse effect of the absorption of heat in excess of that generated when an impressed current of electricity passes across a junction of two dissimilar metals. This phenomena, discovered by Peltier, is discussed by the author for both iron-constantan and copper-constantan junctions. The direction in which an induced current is forced through the junction affects the phenomenon at the junction and it is stated that if the impressed current is passed from the constantan to the iron the junction will be cooled, while if the current is sent in the reverse direction the junction will be warmed beyond the resistive heating of the joints. The author has given full consideration to the physical and mathematical aspects of the phenomena and has derived characteristic curves indicating the qualities under varying conditions for the two types of two metal junctions considered. — *Electrician (England)*, March 16, 1928.



*Temperature fall of two-metal functions with impressed currents*

*The Theory of the Electrical Breakdown of Gases at Atmospheric Pressure.*—LEONARD E. LOEB.—The general theory of the electrical spark, as advanced by Townsend some years ago, is accepted by the author as describing the phenomena with essential accuracy. Other investigators have assailed certain assumption made by Townsend on the basis of measurements made at low pressures in the inert gases with different electrode materials. Their criticisms, while cogent, are more directed at developing their own theories, so that they miss some of what appears according to the author to be the essential significance of the phenomena. It is the avowed purpose of this article to point out these facts in the hope that more work will be done on these features in laboratories equipped for such work. After a brief summary and discussion of Townsend's theory of the electrical breakdown of gases in the light of certain recent criticisms it is shown that these are compatible with his theory except for one serious discrepancy. This discrepancy lies in the fact that at the assumed fields at which breakdown occurs in air, at atmospheric pressure, and in inert gases at low pressures, the positive ions are incapable, at these fields, of acquiring the ionizing energy. Various solutions proposed are discussed and found inadequate. It seems necessary, in order to keep this otherwise successful theory, to doubt the validity of the assumption generally made for plane parallel electrodes that the potential drop between the plates is uniform before the spark passes. It is shown that such fields are possible under the conditions of the spark potential experiments, due to space charges resulting from the difference of ionic and electronic velocities. —*Journal of the Franklin Institute*, March, 1928.

### *Miscellaneous*

*Earth Pressure on Flexible Walls.*—R. N. STROYER.—The author states that it is a matter of general knowledge that sheeting piles, both timber and reinforced concrete, are usually much lighter than would be required to take the earth pressure behind them, if the latter is calculated in the ordinary way, but that it is not generally recognized that earth pressure and the resulting bending moment on the sheeting vary with the thickness of the latter and that, within certain limits, the thinner the sheeting the smaller is the bending moment thereon. This problem has been subjected to critical analysis and as a result certain principles have been developed by the author as a result of theoretical and experimental investigations. —*Engineering (England)*, March 9, 1928.

*Thermal Expansion of Alloys of the "Stainless Iron" Type.* — PETER HIDNERT and W. T. SWEENEY. — The increasing use of low-carbon iron-chromium alloys of the stainless iron type in turbines, chemical processes and articles which must resist corrosion led to the investigation recorded by the authors. As the result of tests upon nine samples of stainless iron of varying compositions values were plotted. It is stated by the authors that data relating to the critical regions indicate that an increase in the chromium content of stainless iron generally causes a slight increase in the temperature at which the transformation occurs on heating. The contraction during the transformation on heating decreases with increase in the chromium content. A tabular summary gives average coefficient of expansion derived from data on all samples of stainless iron. The coefficient of expansion increases gradually with temperature.—*No. 570 Scientific Papers of the Bureau of Standards.*

# Book Reviews

## *An Introductory Textbook of Electrical Engineering*

By John Robert Benton, professor of physics and electrical engineering University of Florida. Boston: Ginn & Company, 1928. 347 pages. Price, $3.60.

Professor Benton has produced a clear-cut exposition of the fundamentals of electrical engineering which should be useful to students possessing some knowledge of college physics and helpful to engineers specializing in other than electrical fields. It offers a refreshing review of principles and major apparatus features to the electrical specialist who seeks from time to time to renew his mental youth by contact with phenomena and laws underlying modern practice, although it does not pretend to serve the daily needs of the expert or to take the place of a handbook. Most of the mathematics used is simple in form, but throughout the book the quantitative viewpoint is apparent, the value of measurement being pressed home to the reader until it becomes second nature in his approach to the problems of the electrical field. The sections on vector analysis, generator principles and alternating-current theory are particularly well done, and there is a good index. The author has wisely kept the complex and specialized laws of electron engineering and so-called static electricity well out of the work, confining his book to the important field of power apparatus, fundamental design and applications. A bibliography of rather limited scope is included, and this might well be enlarged in future editions.

## *Electro-Farming*

By R. Borlase Mathews. London: Ernest Benn, Ltd. 300 pages, 100 illustrations. Price, 25 shillings.

In speaking of rural electrification in Europe the author of this book remarks that the progress "in the various regions seemed to depend largely upon the energy and initiative of the engineer in charge of the local electricity supply undertaking." If he were making a survey of rural electrification in the United States he would probably make the same remark as applying to this country.

Much of the material included in this book has been accumulated by the author from direct observation and experience with electricity on his own farm in Great Britain. On this farm he has 67 different applications of electricity. It would seem, then, that the book must possess some element of authority. The matter of the book is not confined alone to farm applications of electricity, although these are set forth in sufficient detail, but includes also an understanding discussion of the characteristics of rural lines, their effects upon general system conditions and method of rural transmission and distribution. Rural industries in which electricity may be profitably employed and which make use of indigenous raw materials are given some space in the book. There are chapters devoted to special applications of electricity directly and by means of electric light to plant culture and forcing. Electro-silage receives consideration, as do also uses of electric power for plowing, harvesting, handling crops, threshing and soil fertilization. Electrical applications in the farm home, including cooking and refrigeration, have not been neglected. It would seem as though this book would be of value to project directors and rural service specialists to give them that viewpoint on their daily problems which is always obtained from a knowledge of how those problems are attacked in another country.

## *Electrical Engineering Practice*

Vol. II. By J. W. Meares and R. E. Neale, fourth edition, revised. New York: John Wiley & Sons. 668 pages, illustrated. Price, $6.50.

This book was written to fill the gap between the text book and the specialist's book. The authors have compiled a practical work devoted to energy transformation, methods of converting electricity, batteries, distribution and wiring practice and applications of electricity to welding, heating, lighting and cutting. The book is elementary in technical features and uses very little mathematics. It is written for the practical engineer and contains many good illustrations, charts, tables and drawings of a practical nature. The authors are Englishmen, but American engineers will find the treatment of distribution and wiring especially interesting. It covers English practices as laid down in the I. E. E. wiring rules and gives details of accessories and methods of installation. In the chapters devoted to electrical applications general principles are discussed, and data and practical applications to illustrate their use are given. This book should serve very well as an elementary practical text book and for reference.

## *Elektrowärmeverwertung*

By Ing. Robert Kratochwil. Munich and Berlin: R. Oldenbourg. 695 pages, 431 illustrations.

Power companies and manufacturers abroad as well as in the United States are recognizing the importance of electric heating as a load builder of most desirable characteristics. The present treatise, now in its second edition, is written from that point of view by an Austrian engineer who has evidently studied the subject from its economic as well as its technical aspects, and has not been limited by national frontiers, language or the Atlantic Ocean in his search for material; it is by far the most comprehensive publication dealing with the numerous forms of electric heat applications in industry, in the home and in agriculture that has come to the reviewer's attention. In addition to descriptive matter, there is a considerable fund of test data, a discussion of rates in various countries as they affect the sale of energy for heating, and comparative figures on competitive heat sources. The last-named group includes studies on the heating of rooms. A long bibliography shows that much material has been published on the subject under consideration, but it does not seem heretofore to have been adequately coordinated.

## Book Notes

Central-Station Voltages. By Lamp Committee. New York: National Electric Light Association. 95 pages.

This book is distributed by the National Electric Light Association through its lamp committee with the recommendation to all dealers in lamps that only the lamps of voltage specified be supplied for use on the circuits of the central station. The data are kept up to date by voluntary reporting by utilities of changes in voltage.

Laboratory Notes for Electrical Engineering Students. By A. R. Nissar. Calcutta, India: The Calcutta Technical School. 57 pages. Price, 75 cents.

Involves suggestions for 92 groups of studies regarding electrical circuits, apparatus, etc., prepared in such a way as to stimulate the student's initiative and reasoning power. For example, it instructs the student to draw connections for certain tests, conduct tests taking different readings, calculate and plot results, explains theories, etc. This book presupposes a knowledge of electrical theory, as it presents none itself.

## Books Received

*The Story of Public Utilities.* By Edward Hungerford. New York: G. P. Putnam's Sons. 384 pages, 81 illustrations.

*A Century of Industrial Progress.* Edited by Frederic William Wile. New York: Doubleday, Doran & Company, Inc. 581 pages. Price, $5.

*Materials and Design in Turbo-Generator Plant.* By O. Lasche and Walter Kieser. English edition by A. L. Mallenby and U. R. Cooper. 204 pages, 363 illustrations. Price, 24 shillings.

*Grundlagen der Wechselstromtheorie.* By Dr. Ing. P. B. Arthur Linker. Berlin: Georg Stilke. 245 pages, illustrated. Price, 18 marks.

*Die Messwandler.* By Dr. I. Goldstein. Berlin: Julius Springer. 166 pages, illustrated. Price, 13½ marks.

*Electric Winders.* By H. H. Broughton. New York: D. Van Nostrand Company. 402 pages, illustrated. Price, $15.

*The A.C. Commutator Motor.* By C. W. Olliver. New York: D. Van Nostrand Company. 281 pages, illustrated. Price, $7.50.

*Matter, Electricity, Energy.* By Walter Gerlach and Francis J. Fuchs. New York: D. Van Nostrand Company. 427 pages, illustrated. Price, $6.

*Transmission Line Engineering.* By W. W. Lewis. New York: McGraw-Hill Book Company. 361 pages, illustrated. Price, $4.

# News of the Industry

## Portland Defeats Merger

*Oregon Metropolis Votes Two to One Against Permitting Sale of Northwestern Electric Company to Portland Electric Power*

VOTING at a special election called April 9 by the City Council for the purpose of permitting them to approve or reject the plan of the Portland Electric Power Company to purchase the physical properties of the Northwestern Electric Company, the people of Portland raised a decisively negative voice. The final count showed 30,028 votes against to 14,513 in favor of the measure, or a ratio of more than two to one against the proposal, with about a 50 per cent vote cast. Only 24 out of the 486 precincts returned a favorable majority, in each case a narrow one, while in many precincts the ratio against ran five to one or greater.

The proposal to merge the companies and thereby to effect a large annual saving in fixed charges and operating expenses now incurred in operating the duplicated systems had come from the companies themselves, which offered to return these savings to the ratepayers in the form of reduced rates. New and decreased rate schedules had been filed with the Public Service Commission of Oregon and by order of that body had been made effective if and when the sale should be consummated. Under the proposed new tariffs 87,000 domestic customers would have saved $200,000, 9,300 commercial lighting customers $125,000, and 2,000 industrial power customers $100,000.

The franchise of the Northwestern Electric Company prohibited the sale of the company to a competitor without consent of the City Council. The expense of the special election was defrayed by the companies.

## Super-Power of Illinois to Build Powerton Plant

Rapid completion of the first unit of the great new Powerton steam-electric generating station of the Insull companies, to be erected on the Illinois River near Pekin, 12 miles southwest of Peoria, is apparently assured by the authorization granted last week by the Illinois Commerce Commission to the Super-Power Company of Illinois to proceed with the work.

The purpose of building the Powerton station is to combine in one large modern plant individual units in excess of 50,000 kw., thereby obtaining mass production to the four utility companies it will serve—the Commonwealth Edison Company of Chicago, Public Service Company of Northern Illinois, Illinois Power & Light Corporation and Central Illinois Public Service Company. The power house proper is already entirely completed for the installation of two 55,000-kw. units, and the first turbine, boilers and auxiliaries are being installed and are expected to be in operation by Oct. 1. It is expected that the second unit will be ready for operation a year later.

The company is also building three high-voltage electric substations and approximately 55 miles of 132,000-volt steel-tower transmission line extending from Powerton to a point 2½ miles east of Kewanee, Ill., where it will interconnect with a similar line of the Illinois Power & Light Corporation. Then it goes east to Seneca, interconnecting with a line of the Public Service Company of Northern Illinois. The latter line interconnects at Joliet with the network of the Public Service Company of Northern Illinois, which is interconnected with the Commonwealth Edison Company's lines. A second steel-tower transmission line of 132,000 volts, approximately 5 miles long, is being built to interconnect the station with the lines of the Illinois Electric Power Company.

## Transportation to N.E.L.A. Convention Arranged

Although the annual convention of the National Electric Light Association, to be held at Atlantic City in the week of June 4, is still nearly two months away, the association through its traffic manager, Ross I. Parker of the Chicago office of the General Electric Company, has already made the following arrangements for special trains:

The Pennsylvania Railroad will run a special train from Chicago to Atlantic City, with special pullmans from Detroit, Cleveland, St. Louis and Kansas City, leaving Chicago on Sunday, June 3, at 1:15 p.m., Central standard time, and arriving at Atlantic City on Monday, June 4, at 10.30 a.m., Eastern time. Western delegates, their families and guests, are urged to use this train.

There will be a special train from Atlantic City to New York on Friday, June 8, leaving the Atlantic City Pennsylvania Railroad Station at 3.30 p.m., Eastern time, arriving at the Pennsylvania Station, New York, 6.40 p.m., Eastern time. This will be an all-parlor-car train, scheduled to make the run from Atlantic City to New York in three hours and ten minutes.

An all-pullman special train will leave the Atlantic City Pennsylvania Railroad Station on Friday, June 8, at 3.35 p.m. Eastern time, and arrive in Chicago at 10.10 a.m., Central time. Stops will be made at Mansfield, Ohio, and Fort Wayne, Ind. No arrangements have been made for special trains from New York or vicinity to Atlantic City in view of the frequent train service.

## Vetoes Sargent Bills

*Governor Smith of New York Finds Them Unnecessary and Inimical to the Preservation of State Forest Lands in the Adirondack Region*

CONTRARY to the expectation of many who have followed water-power matters in New York State, Governor Smith has voted the two Sargent water-power bills, affecting possible hydro-electric sources in the Adirondack region, which passed the Legislature with little opposition in the last days of the session. They had for their ostensible purpose the prevention of the use of Tupper and Saranac Lakes for a river-regulating district development. They also provided that the state should investigate with the idea of ultimately imposing a charge upon the people benefited by a river-regulating development from the standpoint of the amount of water power that might be produced.

These bills had the indorsement of men and organizations interested in scenery preservation who joined hands with the Governor in 1923 to defeat the constitutional amendment then submitted to the voters to permit hydro-electric development on a small part of the state reserve and a transmission line through the forest. Governor Smith, however, found reasons other than esthetic ones for disapproving the bill. He said in his veto message:

> Both of these bills seem to me to be unnecessary. No river-regulating districts or dams can be set up in the resorts proposed to be protected in the one bill unless there is actual river regulating to be done, and there is no evidence that these particular resorts could conceivably be part of any reasonable river-regulating scheme. The returns to the state in connection with power developments cannot be fixed by law. All that the law can provide is the administrative machinery under which a reasonable return to the state can be determined. The state already has such an agency in the Water Power and Control Commission.
>
> It is, therefore, clear that the bills are not needed, and the obvious inference is that they will operate in the interest of the groups whose main object is to develop power in the Adirondacks at the expense of the great forest preserve which we have built up, contrary to the provisions of the constitution and against the interests of the great majority of the people of the state. There must be some good reason why the property holders in the finest sections of the Adirondacks not owned by the state are alarmed by demands for power developments. They live in these sections and must know what is threatened. I do not propose by any act of mine to agree that they need protection of this kind nor by any implication to abandon other sections of the Adirondacks to power developments.

Some political observers at Albany

see the origin of the bills in a feud between power companies and paper manufacturers over rights to hydro sites in the mountain region, but if this "angle" exists, the veto message does not allude to it.

## Flathead River License Applied For

*Rocky Mountain Power Company Wants to Develop Initial 80,000 Hp. There — Permit on Chattahoochee Sought—Licenses Asked for Gauley and Sultan Rivers*

APPLICATION to the Federal Power Commission has been made by the Rocky Mountain Power Company of Butte, Mont., for a license covering one of the five sites on the Flathead River included in its preliminary permit. As the first step in the development the company proposes to erect a dam, 180 ft. high, which will regulate Flathead Lake and permit it to act as a reservoir. It is planned to install 148,000 hp. at the first dam, where 80,000 hp. of primary power will be developed. The difficulty represented by the Newell tunnel has been removed through the passage of the Interior Department appropriation bill. A conflicting application is on file, but prospects favor granting the license.

The Columbus (Ga.) Electric & Power Company has applied for a preliminary permit covering two dams and power houses on the Chattahoochee River in Georgia and Alabama. One of the sites is near Maple Creek and one near Houston Island. It is proposed to install 40,000 hp.

Having completed the work called for in its preliminary permit, the Gauley Power Company of Charleston, W. Va., has applied to the Federal Power Commission for a license covering the project it has been examining on the Gauley River, in Fayette and Nicholas Counties, West Va. The company plans to construct a concrete dam 125 ft. high at a point 21 miles from the mouth of the river, where, it is estimated, 54,500 hp. of primary power will be made available. It is proposed to install three 20,000-hp. generators. This is one of the few applications received from West Virginia since the enactment of the water-power law—a fact attributed to the unsatisfactory character of the state law.

The Washington Electric Company of Seattle has applied for a preliminary permit covering a project on the Sultan River near Sultan, Wash. It is proposed to build a dam 310 ft. high which will create a reservoir of 230,000 acre-feet capacity. Estimates of electrical output have not been received.

J. B. McConley and F. A. Hebbard of San Francisco have applied for a license covering a small dam on Canon Creek in Trinity County, Calif. The primary power available is 520 hp.

The Pacific Gas & Electric Company of San Francisco has applied for a license connected with completed projects on the Yuba and American Rivers.

## Restraining Order Vacated in Cambridge Rate Case

Judge Morton of the United States District Court in Massachusetts issued a decision on Wednesday vacating a restraining order which prevented the Department of Public Utilities from enforcing its recent decision reducing the domestic and commercial lighting rate of the Cambridge Electric Light Company from 8 cents to 5 cents per kilowatt-hour. The opinion holds that, pending a hearing of the case before a master, reasonable doubt exists as to the company's contention that the commission's decision will cause it grave and irreparable injury. No reasonable probability exists, in the court's view, that the utility will prevail upon final hearing.

The District Court is not satisfied that the commission's valuation, arrived at in this case under the reproduction-cost rule of the United States Supreme Court, is based upon some fundamental error of either fact or law; that a return of less than 8 per cent would *ipso facto* be confiscatory, or that the return which the company will actually obtain under the new rate will be of that character.

## Storms Hamper Utilities in Nebraska and Ohio

A Middle West snowstorm with high winds that lasted the greater part of Friday, April 6, caused pole and wire damages totaling $100,000, the principal sufferers being the Nebraska Power Company, with an estimated damage of $50,000, and the Iowa-Nebraska Light & Power Company. As telephone and telegraph communication was interrupted for many hours, the work of rehabilitation was considerably delayed. This was especially true of the latter company, because of the wider distribution of its lines. The wet snow clung tenaciously to the wires, and the wind that followed within a few hours after it began to fall pulled down long pole-line leads and inextricably tangled miles of wire.

General Manager Davidson of the Nebraska Power Company, Omaha, said that while temporary repairs had enabled the company to resume service, many rural lines would have to be reconstructed. The same opinion was expressed by General Manager Brooks of the Iowa-Nebraska company. The storm area covered eastern Nebraska and western Iowa, and telegraph and telephone companies estimate their total damages at close to a quarter of a million dollars.

Damage to the extent of more than $750,000 to various utilities is reported as the result of a sleet storm which swept over northwestern Ohio on March 29. Electrical and communication service was particularly hard hit in the city of Findlay, more than a week's effort proving necessary for its complete restoration there. The Toledo, Bowling Green & Southern Traction Company, which supplies Findlay with light and power, suffered also from the crippling of its interurban railway service, but has emerged from its troubles. The loss to this company is placed at $100,000.

## Ashurst Presents Views

*Arizona Senator Makes Clear the Position of His State in a Minority Report from Him on the Swing-Johnson Boulder Dam Bill*

WHETHER or not the states are sovereign over their own waters, excepting in matters pertaining to navigation, is the great question involved in the Boulder Canyon bill now before the Senate, according to Senator Ashurst of Arizona, who has submitted his minority report on the bill. He characterizes this legislation as a reckless and relentless assault upon his state. Senator Ashurst's minority views cover 38 printed pages. He sums up Arizona's position as follows:

> Arizona cannot, under any circumstances, yield her right to an equitable share of the waters of the Colorado River available for use in the lower-basin states. This water is absolutely essential to Arizona's development. It represents the only possibility of the reclamation of a large tract of her arid but exceedingly fertile and otherwise highly favored land. It means, at some time in the not remote future, population, homes, taxable wealth, prosperity and the subsisting of peoples. Aside from the question of the rights of states and of geographical boundaries, the deprivation of this land of an opportunity for development would mean a tremendous economic waste, both in the production of crops and in the duty of water.
>
> Arizona has 1,500,000 acres of land, easily susceptible of irrigation from the main stream of the Colorado River. It is land highly favored both by soil and climatic conditions and lies adjacent to the Colorado and Gila Rivers in the southwestern portion of Arizona. It requires only water to make it tremendously productive of crops of a highly valuable character and which can be produced only to a limited extent in the United States. This land drains back into the Colorado and Gila Rivers, and its irrigation will therefore result in a return flow and in an important saving of water over the irrigation of land having no drainage, where the water actually used on the land as well as the surplus flowing in the canal is forever lost. Through engineering feats of the greatest proportions all of the water of the Colorado River might be placed by gravity upon Arizona land, but no questionable engineering feat is involved in the utilization of Arizona's fair division of the water available for use in the states of the lower division. This is Arizona's claim, which she presents for the consideration of all who are fairly disposed toward the principle of equity and justice. It may be true that with only one-half of the water in the lower basin at her disposal some of California's desert land could not be watered. If so, no hardship would be suffered by that state which would not likewise be visited upon Arizona. If some acreage must forever be arid, there is no sound reason why Arizona should be singled out to bear the burden and the loss.
>
> This bill is ruthless and cynical. It swarms with cryptic phrases. It is not the voice of compromise or an extension of the hand of amity and friendship.

# Electric Progress Rapid in North Carolina

*Next Year 90,000 Hp. Will Be Added to This Spring's Hydro Installation of 205,000 Hp. at Three Sites—Riverbend Steam Plant*

THE plant of the Carolina Power & Light Company on the Pigeon River in North Carolina, near the Tennessee state line, will be completed next year with a capacity of 90,000 hp., to be raised ultimately to 135,000 hp. The North Carolina Department of Conservation and Development points out that this plant is of particular interest as differing from all existing hydro-electric projects in the state in its type of development. All the major water-power developments in the state have heretofore been constructed on the larger streams in the Piedmont region and are dependent on producing a fall entirely by the construction of dams from 50 ft. to 200 ft. in height. The Pigeon River development makes use of a relatively small mountain river, but by diverting it through a tunnel in the mountains over four miles long causes the water to fall down the mountain sides through steel pipes to a power house far removed from the dam, thereby developing a total fall of 861 ft.

The Pigeon River development, when it is ready, will follow three others in North Carolina which have just gone into operation or will soon do so. These are the Santeetlah plant of the Tallassee Power Company, supplying the Aluminum Company of America, where a 66,000-hp. installation is now in operation; the Carolina Power & Light Company's Norwood plant on the Yadkin River, with 83,000 hp., and the Duke Power Company's Oxford Shoals plant on the Catawba, near Hickory, with 56,000 hp.

With the Duke Power Company's completion of its hydro-electric plant at Oxford Shoals and the letting of contracts in connection with the first 112,000-kw. unit for its coming steam plant at Riverbend, on the Catawba, designed to produce ultimately 450,000 kw. and which will cost more than $20,000,000, it is forecast that the Piedmont section of the Carolinas will experience an inflow of new business. In the last five months, in fact, Duke company officials say, 43 new industries have been established in that section.

# Electrical Papers on Program of Missouri Association

Seven or eight papers related to the electrical industry are scheduled for presentation at the twenty-second annual convention of the Missouri Association of Public Utilities, which will be held at Jefferson City on April 26-28. These include:

*Thursday, April 26.*—"Industrial Development of a Territory by the Public Utility Company Working in Conjunction with the Chamber of Commerce," F. S. Dewey, vice-president Kansas City Power & Light Company.

*Friday, April 27.*—"Economic Changes in the Light and Power Industry in Missouri and Their Value to the Public," L. A. Pettit, Jr., vice-president Missouri Power & Light Company, Kansas City; "The Public Utility Company's Responsibility in Relation to Street Lighting," L. A. S. Wood, Westinghouse Electric & Manufacturing Company, South Bend, Ind.; "Load Building—The Commercial Man's Obligation and Opportunity," W. L. Berry, Union Electric Light & Power Company, St. Louis.

*Saturday, April 28.*—"Electricity in Missouri Agriculture," Prof. M. M. Jones, University of Missouri; "What a Farm Woman Thinks of Electricity on the Farm" (illustrated), Mrs. Aubrey Fellows, Salisbury, Mo.; "Desirability of District Steam-Heating Business in Connection with Central-Station Service" (illustrated), T. S. Ayers and W. C. Kaber, St. Louis.

# Need More Subscriptions for Louvain Gift

A total of $61,729 has been subscribed up to date toward the fund for the clock and carillon which the Engineering Foundation is presenting to the University of Louvain. This sum represents 2,662 subscriptions. As the gift will cost $80,000, there is still needed nearly $20,000, and the committee in charge is appealing to the engineers who have not yet subscribed to act promptly in the matter. A generous response is confidently anticipated.

The new memorial library at Louvain will, as already published, be dedicated on July 4 in the presence of an American delegation. It is hoped to arrange to have the United States national anthem played on the evening of that day by the new chorus of bells and to have it broadcast across the Atlantic so that it may be heard in this country about noon.

# New Brunswick Approves Tidal Power Project

An exceptionally keen battle has just been concluded in the New Brunswick Legislature by the passing of what is known as the Cooper Dam bill, involving the right to develop power from the tidal waters of the Bay of Fundy. This is a companion bill to the one already passed by the Maine Legislature. Those favoring the bill stressed the vast amount of power which the project is designed to develop in Passamaquoddy Bay both for Canada and the United States. Adverse opinion pointed to the loss in the fisheries, the change of a valuable harbor into a landlocked lake and the handing over of New Brunswick resources to United States interests. The development plans must be approved by the Canadian Department of Public Works and the International Joint Waterways Commission. The estimated cost of the development was placed at between $50,000,000 and $75,000,000 by the proponents of the bill and its initial development at from 400,000 hp. to 500,000 hp., ultimately to reach 700,000 hp. or 800,000 hp.

# Rochester Gas & Electric's Caneadea Dam

THIS two-million-dollar link in the Rochester Gas & Electric Corporation's proposed Genesee River power development will be capable of producing 8,000,000 kw.-hr. of electrical energy yearly when the power house is completed. The dam, viewed in the picture from the spillway side, stands in Caneadea Creek at Caneadea, N. Y. It is 128 ft. high in the center. The artificial lake will cover 740 acres. The spillway capacity is 12,000 cu.ft. per second. Three villages disappeared under the reservoir.

## Legislation, Platforms and Stump Speeches

*Virginia Passes Water-Power Bill—Agitation Subsides in Oregon—"Power Trust" Denounced in Nebraska and Wisconsin—Ohio "Pence Law" Attacked—Maine Water-Power Issue*

A BILL placing regulation of water-power development in Virginia under the State Corporation Commission has been signed by Governor Harry F. Byrd. This measure, which is regarded as of considerable importance to hydro-electric projects, was introduced in the Legislature at the instigation of the State Conservation and Development Commission.

A review of 75 pre-election statements contained in that number of petitions filed to date by candidates seeking legislative offices in Oregon indicates that the state's 1929 Assembly will be remarkably free from bills affecting the development of hydro-electric power and the utility business in general. There have appeared so far no "slogans," pledges or recommendations in connection with proposed laws affecting the utility industries, although matters of this character have occupied first place in pre-election statements for twelve years past.

The so-called "power trust" constituted a big issue in the primary campaign for the Republican nomination for United States Senator in Nebraska, with Attorney-General Spillman detailing at length to the voters in dozens of towns the story of how he secured a permanent injunction at Hartington that "halted the progress of the conspiracy among the big companies to destroy municipal competition." Senator R. B. Howell, who won his fight for renomination, insisted that his record as a foe of monopoly and corporations entitled him to another term and publicly charged that the "power trust" was supporting Spillman in spite of his speeches.

A bitter attack on the "power trust," the Federal Trade Commission, Samuel Insull and others was made at Racine, Wis., by Senator Robert M. LaFollette in a plea for sending a Wisconsin delegation of progressive delegates to the Republican National Convention at Kansas City. "The power monopoly is a hierarchy of construction companies, advisory companies, financial companies, holding companies, super-holding companies and super-super-holding companies, each with a separate organization to be maintained and a separate profit earned," said the Senator. "They own newspapers, they finance election campaigns, they hire expensive attorneys and legislative counsel to lobby in their interests at the national and state capitols, where they ingeniously oppose every activity that might tend to reduce their indefensible profits."

Writing as a champion of Ohio farmers, Charles H. Hubbell, a Cleveland attorney, has addressed letters to candidates for Governor asking each what he would do to adjust electric rates in rural Ohio should he be nominated and elected. "What specific steps will you take to see to it that rural Ohio gets adequate electric service at fair and reasonable rates?" asks Mr. Hubbell. "Will you put a farmer on the commission? Will you favor repeal of the Pence law?" The Pence law makes it possible for public utilities to increase rates under bond pending decision of the Public Utilities Commission.

At the state Democratic convention held at Waterville, Me., recently two mutually antagonistic planks were debated—one calling for the exportation of power outside the state and the other declaring against the repeal of the Fernald law, which forbids such exportation. Agreement was reached on a plank permitting exportation of power under state control. Both parties are divided on the question, which will loom large in the coming campaign. Governor Brewster defends the Fernald law, declaring that Maine is not lagging in the production of electrical energy and has no surplus of primary power. These contentions are disputed by the power companies.

---

## "Electrical World's" London Letter

### Results of National Electric Week Bring Suggestion of "Electrical Fortnight"—Disadvantages of Municipal Control of Generation—Electrical Engineers as Scapegoats

By Bernard C. Holding
Editor of *The Electrician*

LONDON, March 30.

SINCE I last wrote it has been possible to form a more accurate estimate of the real effect of the first National Electric Week ever organized in this country. Although the campaign, of which details have been given in earlier letters, seems to have had very little effect on sales, most of the participants agree that the effort was worth the time and money expended upon it, even if only for its propaganda value. Moreover, there seems to be a fairly widespread desire for an effort of longer duration than a week, and the idea of an "Electrical Fortnight" for 1928 is finding considerable backing. There seems to exist a curious difference of opinion as to whether the newspaper advertising of a campaign of this kind should comprise fairly large spaces, appearing at comparatively long intervals in selected papers, or small spaces published with great regularity in a large number of papers on lines similar to the famous "Eat more fruit" campaign.

The municipally owned electricity supply authorities in this country have certain advantages over the company undertakings, but, as recent happenings have shown, they labor under very heavy disabilities. These municipal undertakings are normally run by a competent electrical engineer who is paid by the municipality and who is assisted by an "electricity committee" composed of selected members of the local governing authority. There are, however, a number of towns in which the engineer is placed at a disadvantage through the existence of an electricity committee composed of people possessing the most rudimentary ideas regarding not only electricity supply but also the running of any sizable business, and who, perhaps through ignorance, but more often for local political motives, hamper the work of their engineers.

While this state of affairs is by no means new and can usually be borne, there have been several cases of late where the folly of such a system of governance has been proclaimed for all to see. In one town possessing an electricity committee of no fewer than 23 members, who met for a few minutes only once a month, charges were made of inefficient working, unnecessary expenditure on plant and so on. Fortunately for him, the engineer concerned was able to bring about an inquiry by a well-known consulting engineer, whose report not only acquitted him of all the charges, but also made recommendations which are in course of being carried out to replace the unwieldy committee of laymen by a small panel of five business men of repute.

Less fortunate, however, has been the case of the engineer of another municipal undertaking with an annual generation approaching 250,000,000 kw.-hr. Charges of inefficient administration, unauthorized expenditure, etc., have been leveled against this engineer by the very people who were appointed by their fellow citizens to check such items, and his resignation was called for. The indignation aroused by this action has reverberated throughout the country, but, despite criticism, the municipality concerned has refused to have an impartial inquiry and is leaving further investigation of the allegations to a sub-committee chosen from the electricity committee, which, if there is any substance in the charges, was jointly responsible with the engineer it has chosen as its scapegoat. Here the matter rests for the moment, but there is a growing feeling that incidents of this kind may be repeated from time to time unless some radical change is made.

The first of the co-ordinated regional schemes of generation and transmission, which, as I have stated in an earlier letter, is concerned with south-east England, including the important area of Greater London, has now undergone revision at the hands of the Central Electricity Board and has been very considerably modified in the process. Into the detailed changes it is impossible to enter here, but some idea of their sweeping nature may be gathered from the fact that eighteen more generating stations are to be added to the thirteen "selected" stations included in the original scheme. There were many objections to the original scheme put forward by the Electricity Commissioners last October, but the vastly different scheme which is now to go forward seems to meet with general approval.

An effort which should exert a quickening effect on domestic electrification is about to be launched by the Electrical Association for Women, an organization which exists to interest women in the possibilities of electricity in the home. The plan of campaign is that, after deciding upon a national specification showing the desirable number and position of electrical outlets in each room of the modern house, members of the association shall pay visits to all new housing estates throughout the country and arrange deputations to architects, builders, housing authorities, and eventually to the Minister of Health, with a view to pointing out the discrepancy between the electrical needs of the home-maker and the provision that is being made to meet those needs. It is obvious that this mass demand from the potential occupants of new houses will be more effective than a trade-organized attempt to achieve the same purpose.

## Philadelphia and Baltimore Utilities Resume Fight

Having failed to settle their controversy over the right to serve Havre de Grace, Md., and adjacent territory in Harford County after several months of negotiation, the Consolidated Gas, Electric Light & Power Company of Baltimore and the Philadelphia Electric Company, owner of the Northern Maryland Power Company, will resume their fight in the Circuit Court for Cecil County, Md. This case, springing from a rivalry which probably envisages more than merely supplying a small territory with light and power, has been reported from time to time in the ELECTRICAL WORLD.

A suit by the Philadelphia company to set aside the order of the Public Service Commission granting the Baltimore company the right to serve Havre de Grace was postponed in Cecil County last January. The Baltimore company asked for the postponement so as to ascertain whether a settlement could be arranged by which it would buy the property of the Northern Maryland Power Company.

Inability of the two companies to agree on a price for the property has resulted in the termination of negotiations, and the Philadelphia company has instructed its counsel to have the case set for a hearing at an early date. The Maryland Public Service Commission, a codefendant with the Baltimore company, is opposed to an early trial. Meanwhile work on a transmission line from the Conowingo hydro-electric plant to the Northern Maryland system at Havre de Grace is to be begun by the Philadelphia interests.

## Purchases and Mergers

*Montana Power Company Is Acquired by American Power & Light—New York and Many Other States See Numerous Shifts in Control*

AN UNUSUALLY important transfer of utility property was effected when, as officially announced on April 6, the Montana Power Company and the American Power & Light Company agreed to merge, subject to the approval of stockholders. The combined capital investment of these two companies amounts to $115,000,000. The necessary corporate action will be taken by shareholders about April 24. Financial details of the merger will be found under "Financial and Statistical News."

The American Power & Light Company, which is managed by the Electric Bond & Share Company, has recently taken control of the Washington Water Power Company (ELECTRICAL WORLD, Jan. 21, page 166, and March 24, page 627), whose system is interconnected with that of the Montana Power Company. The American Power & Light controls also large operating properties in Kansas, Nebraska, Minnesota, Texas, Florida, Oregon and other states. As elsewhere reported, by a vote on Monday of this week in Portland, Ore., the electors of that city refused to allow purchase of the Northwestern Electric Company by the Portland Electric Power Company, thus leaving the former still the property of the American Power & Light.

The Montana Power Company, of which John D. Ryan has been the president and directing power, has, it is believed, for years resisted efforts to acquire it. Closely associated with the Anaconda Copper Mining Company, it has enjoyed much prosperity, controlling hydro-electric subsidiaries at Great Falls, Mont., and elsewhere.

The Associated Gas & Electric Company has purchased the Delaware & Otsego Light & Power Company of Franklin, N. Y., serving that place and nearby communities. Headquarters have been moved to Ithaca.

A certificate has been filed by the Plattsburg Gas & Electric Company in the office of the Secretary of State at Albany, N. Y., announcing merger with the Eastern New York Electric & Gas Company, Inc., of Granville and assuming that name.

A court decision has been handed down in the Hammond Light & Power Company case referred to in these columns on March 24 (page 627) favoring F. A. Southgate and his associates in the St. Lawrence County Utilities, purchasers of 54 per cent of the Hammond company's stock, and declaring illegal the election of directors by Michael Doyle and associates of the Oswegatchie Light & Power Company, who had bought 46 per cent.

Application has been made to the New York Public Service Commission to permit exchange of the capital stock of the Cortland County Traction Company for stock of the Mohawk-Hudson Power Corporation. The traction company for 35 years has operated the Cortland light and power plant, supplying also Homer, Preble, McGraw and surrounding territory. It is capitalized at $320,000.

Purchase, already noted, by the Interstate Public Service Company of four small electric properties in and near Columbus, Ind., for $97,500 has been approved by the Indiana Public Service Commission. The companies are the H. F. Clevenger Electric Company, Columbus; the Trafalgar Light & Power Company, the Winterrowd Electric Company, Flat Rock, and property owned by H. F. Clevenger south of Columbus.

Voters of Caldwell, Kan., have approved the sale of the city's electric light and water plants to the Western Light & Power Corporation, with headquarters at Salina. The consideration was $205,000 cash. The vote also authorized the City Commission to grant a 20-year franchise. The proposal to sell the plants to a former and lower bidder lost several weeks ago, and the vote to sell to the Salina organization was carried by only 74 votes.

Negotiations are under way for the sale by the city of Claflin, Kan., to the United Power & Light Corporation, Abilene, of the municipal distribution system and 8 miles of transmission line.

After having voted down by 513 to 366, at a special election in February, a proposal to sell the municipal electric lighting plant to the Iowa-Nebraska Light & Power Company, College View, a Lincoln educational suburb, has now voted, 411 to 318, to sell for $35,000 in consideration of an agreement by the company to supply gas to the town at the Lincoln rate.

Palmer (Neb.) voters have voted by 154 to 35 to sell the municipal electric system to the Central Power Company, Grand Island, which will build a transmission line there and continue through to Central City, thus effecting a loop. Julian, Neb., also voted with only two dissentients to sell its plant to the Central Power Company.

An offer of $330,000 by the Southern Colorado Power Company for the municipal light and power plant of Lamar, Colo., has been raised to $400,000.

The Northern States Power Company has made a formal offer of $350,000 cash for the competing municipal electric lighting plant at Sioux Falls, S. D. The offer includes all physical property of the system but does not include the buildings and land.

The sale of the Bartlesville (Okla.) Gas & Electric Company to the Southwestern Gas & Electric Company has been approved by the Oklahoma Corporation Commission. The Bartlesville company was formerly a Doherty property.

Purchase of the Burnsville (N. C.) Light, Heat & Power Company, serving Burnsville, Bakersville, Toecane and Micaville, by the East Coast Utilities Company of Chicago is announced. Lines are to be built to Mars Hill and Marshall and to other points in western North Carolina.

The Carolina Gas & Electric Company, whose bid of $1,271,000 for the municipal electric plant of Kinston, N. C., is to be submitted to popular vote in July, after tentative approval by the City Council, now offers to add $86,000 to its bid to make it equal to another one rejected by the Council as vaguely worded. Should the bid be indorsed at the polls, the Mayor of the city advocates paying off the city's debt of $803,000 as it falls due and creating a special fund out of the balance to be spent on such improvements as the voters indorse.

Voters of Athens, Ala., have voted down decisively the proposal to sell the city's plant to the Alabama Power Company for $113,000. This is the third time in about fifteen years that the city has refused to sell the plant.

Waxhaw, N. C., and Walhalla, S. C., in addition to Walnut Cove, N. C. (already noted), have voted unanimously to sell their distribution systems to the Southern Public Utilities Company of Charlotte, N. C.

The Texas Utilities Company has placed

a new power plant in operation at Sonora, Tex., after purchasing the local plant and that at Eldorado.

Application to the California Railroad Commission for authority to acquire the Fair Oaks Electric Company for $37,500, to assume its indebtedness of $9,500 and to consolidate the system with its own has been made by the Great Western Power Company. The Fair Oaks company serves the unincorporated town of Fair Oaks and surrounding territory 12 miles northeast of Sacramento and has been purchasing all its energy from the Great Western Power.

The Mid-West Utilities, Limited, a subsidiary of the International Utilities Corporation, has purchased the plants owned and operated under franchises in southern Saskatchewan, Canada, by the Northern Light & Power Company. The plants taken are those at Broadview, Indian Head, Wolseley, Moosomin and Grenfell.

Shareholders of the Quebec Railway, Light, Heat & Power Company have approved its sale to the Quebec Power Company.

# Three Topics Predominate at Omaha

## Cheap Power as a Magnet for Industry, the Tri-County Project and Rural Service Provide Fruitful Sessions for Meeting of Nebraska N.E.L.A.

Interest at the twenty-seventh annual convention of the Nebraska Section of the National Electric Light Association, held at Omaha on April 4 and 5, centered in the result of a study made by Ford Bates of the Nebraska Power Company of the factor of cheap power in the location of manufacturing industries, in the report of a special engineering committee as to the feasibility of the Tri-County project in central Nebraska, for which government and state aid have been asked by the promoters, and in the progress of rural electrification.

Mr. Bates' study was of Nebraska industries. He found that in the location of industries consideration was first given to the market for the production, then to these other things in the order named: Availability of raw material, transportation, labor supply, building costs, financial accommodations, and, last, cheap power. He instanced the failure of the Keokuk plant to draw industries to it and the final necessity of selling energy to St. Louis, with its thousands of factories and workshops, as typical of the situation.

Roy Page, assistant general manager of the Nebraska Power Company, reported for the special engineering committee that under no one of the five plans for the Tri-County project presented by the government would the power section take care of itself, let alone aid in reducing the cost of irrigating the land as proposed. The committee found that the electrical energy which could be produced there could not compete with existing sources of supply.

The proposal was condemned as economically unsound, and studies were presented which showed that the present sources of production, being nearer the principal power markets of the state, can put out energy at a lower price. Because of the ever-increasing size and efficiency of steam plants and the fact that hydro-plant efficiency has about reached its maximum, making the cost of hydro production almost entirely a function of investment, the development of this and similarly located high-cost large water powers must wait until the nearby market has grown so that the necessary investment will be justified, thus offsetting the high cost of distribution to points of use.

This investigation was undertaken on the theory that if the project offered a more economical source of electrical energy, the power companies should make the development. Dean Ferguson of the University of Nebraska, discussing the report, said that the committee had underestimated and undervalued the possibilties of development of a market in the immediate territory. He thought that taking a smaller unit of development would have yielded more satisfactory results.

### Many Hydro Plants Idle

Dr. G. E. Condra, head of the state conservation department, gave statistics showing that of the 286 water-power developments in the state in past years, only 70 are now operated. One contributing factor was the decline of local power demands, and another was better methods of development.

C. W. Amidon, president of the Central Power Company, which operates both types of plants, gave as the result of his experience that the hydro plant costs more to construct and, because of the interest cost, more to operate, and in Nebraska sand in river bottoms forces a higher maintenance cost. The company's hydro plants were idle many hours last year because of low water and slush ice. The successful method is to develop the load of the steam plant to the point where the hydro is available only for emergency; it cannot be considered as a primary but as a secondary source, to be used only when conditions are favorable. Similar experiences were related by George W. Steinmyer, district manager Iowa-Nebraska Light & Power Company.

L. E. Nelson, Omaha merchant, discussing trade relations, said that the light and power companies were making the competitive situation very difficult for retailers of limited capital. He criticised the use of premiums by the companies in selling merchandising and the terms extended. He had no criiticism of prices. C. N. Chubb, president Iowa-Nebraska Light & Power Company, said that on the power companies was laid the burden of pioneering in both invention and creation of a demand. This department should always be operated at a profit, and he urged co-operation of retailers with power companies.

Great progress in reaching the farmer with dependable service was reported by W. R. McGeachin, assistant general manager Iowa-Nebraska company; S. P. McFadden, general manager Western Public Service Company, and Prof. E. E. Brackett, University of Nebraska. The general opinion was that a service charge with a lower energy rate would promote greater use of energy and prove better in the long run for both producer and consumer. Professor Brackett gave the results of a survey that showed 2,200 rural consumers, only a few of them connected with municipal plants. Rates run from 5¾ cents to 14.42 cents a kilowatt-hour, and the average consumption is 520.8 kw.-hr. per year.

Other features of the program included papers on legal aspects of the year, merchandising methods, service problems, safety conferences, inductive co-ordination, transformer loads, fuel and radio.

C. W. Amidon of Grand Island was named president; S. P. McFadden, Scottsbluff, vice-president; Thorne A. Browne, Lincoln, re-elected secretary, treasurer and managing director. The registration totaled 155.

# Briefer News

**Radio Board Elects Officers.**—Ira E. Robinson of Grafton, W. Va., newest member of the Federal Radio Commission, was unanimously elected chairman at a meeting of the commission late last week, and Judge E. O. Sykes was elected vice-chairman.

**Columbus (Ohio) May Enlarge Municipal Plant.**—Plans for expansion of the municipal lighting plant have been outlined by Service Director Duffy of Columbus, Ohio. They include installation of a 7,500-kw. generating unit, additional distribution systems, new stokers and boiler equipment and a new automatic substation for the South Side, involving a total expenditure of $515,000.

**Ponca City, Okla., Rebuilding Its Plant.**—A new municipal plant is under way at Ponca City, Okla., Superintendent J. W. Crow reports, in which will be installed two 1,125-kva. generators driven by Diesel-oil engines, to which will be added the two engines now in service in the old plant. The total cost is put at $300,000.

**Cedar River Dam to Wait.**—Although the Iowa Railway & Light Corporation has submitted an application for permission to erect and operate a two-million-dollar dam and hydro-electric plant on Cedar River near Rochester, Iowa, Isaac B. Smith, Cedar Rapids, president of the corporation, states that the project will not be actually undertaken for three years or until the present plant proves inadequate.

The new 9,500-hp. project includes a reservoir of 2,250 acres, a concrete dam with a crest 22 ft. above normal water level, a power house 140 ft. long and five hydro-electric units of 1,400 kva. each.

Alouette Plant of British Columbia Company Begins Operation.—The Alouette power plant of the British Columbia Electric Railway Company has received the finishing touches to the equipment, and the plant began generating on March 29. It will be joined to the system of the British Columbia Electric on the lower mainland in the course of a week or so. The plant, which cost $2,500,000 to erect and took approximately three years to complete, was described and illustrated in the Electrical World for Feb. 25 (page 424.)

Petroleum Industry Electrical Association Formed. — Formation at Fort Worth, Tex., of the Petroleum Industry Electrical Association is announced, and immediate steps will be taken to embrace the entire country in the scope of its organization, according to T. J. McMahon of Houston, who was elected president. The association represents an investment of approximately $15,000,000, Mr. McMahon says, and is meant to "weld for mutual helpfulness the entire telephone, telegraph and electrical systems of the numerous oil and gas pipe-line companies and refineries of the Southwest."

Vernonia (Ore.) Light & Power Gets on Its Feet.—Intervening at the request of stockholders and customers of the Vernonia Light & Power Company after litigation failed to give relief, the Oregon Public Service Commission has effected a settlement of the affairs of this company, which has been in the hands of a receiver for the past year. G. W. Ford, formerly manager of the Toledo (Ore.) Light & Power Corporation, will take charge of operation, as receiver, and the commission's engineer has established rules and regulations under which the utility may operate and discharge outstanding obligations.

Empire State Association's Women's Section Meets.—A well-planned program was drawn up for the annual meeting of the Women's Section of the Empire State Gas and Electric Association at Briarcliff Manor, N. Y., on Thursday and Friday of this week. It included papers on "The Home Service Department," by Helen A. Smith, Rochester; "Aids in Teaching the Use of Service in the Home," Marion Brainard, New York; "The Rural Home of Yesterday, Today and Tomorrow," Dr. Ruby Green Smith, Cornell University; "Electricity in the Farm Home," Elizabeth Sweeney; "The Farm Kitchen," Laura Rischman; "Women in Public Utilities," Sara Harris, Utica; "Developing Women's Work in the Public Utilities," Marguerite Bradshaw, Nyack; "Representing the Customer," Florence Everett, New York; "The Public Speaking Committee," Frank W. Smith, New York; "Railroading from a Woman's Viewpoint," Olive Dennis, and "Our Civic Responsibilities," Mrs. Arthur Livermore. Luncheon speakers were to be Mrs. Christine Frederick, Miss Lena M. Prillips and F. W. Fisher, director public relations Rochester Gas & Electric Company.

Dr. Mead Declares that All Irrigation Power Plants Pay.—While on a visit of inspection to the Elephant Butte dam and irrigation project, Dr. Elwood Mead, chief of the United States Bureau of Reclamation, made the statement that all revenues derived from the development of hydro-electric power at that dam will go to the two irrigation districts which are served by the reservoir. Dr. Mead said that the contract of the districts with the El Paso Electric Company for the purchase of power, on which hinges the ultimate construction of the power project, had been informally approved by the Secretary of the Interior. He added: "There is unquestionably a large amount of potential power at the dam and it should be utilized. Development of the power is especially advantageous because of the market afforded by El Paso. There is not a single power plant built on any of our projects that is not profitable. Revenues from the Minidoka (Idaho) plant this year will nearly pay operating expenses of the irrigation project."

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]**

American Institute of Electrical Engineers — Baltimore regional meeting, April 17-19; New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities—Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Arizona Utilities Association—Prescott, Ariz., April 26-28. M. G. Sanders, Industrial Congress Bldg., Phoenix, Ariz.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A. — Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

More Rate Reductions in Kansas.—Voluntary reductions in residence lighting rates in four towns have been announced by the Kansas Power & Light Company, Topeka. The new rate provides for the first 30 kw.-hr. at 12 cents and all in excess at 6 cents; formerly the rate was 15 cents stepped down to 10 cents. Substantial rate reductions to Peabody and Junction City, Kan., have also been voluntarily made by the United Power & Light Corporation, with headquarters in Abilene. These reductions are in line with the Kansas Public Service Commission's policy of lower and more uniform rates throughout the state.

Water Resources of Virginia.—"Water Resources of Virginia," a volume of more than 500 pages containing all data compiled by the steam-gaging stations of the state—some sixty in number—since they began functioning, is just off the press. The book was compiled by the state Geological Survey, an agency of the Conservation and Development Commission, in cooperation with the federal Geological Survey. The data were obtained by J. J. Dirzulaitis and G. C. Stevens, who are in charge of stream-gaging work for the state survey. Stream-gaging work began on some Virginia streams about thirty years ago, and the volume just published covers this entire period. It also includes a summary of the report of the water-power possibilities of the Potomac River system made by Major M. C. Tyler, of the United States Army Corps of Engineers.

Westchester Lighting Company Reduces Rates.—New rates for electrical energy which will save customers of the Westchester Lighting Company and affiliated companies, serving Yonkers, Mount Vernon, New Rochelle, White Plains and other places north of New York City, more than $400,000 a year will become effective on June 1, the company announces. Reductions range from 4½ to 18 per cent. Under the new schedule the charge for the first 50 kw.-hr. used in a month will be 10½ cents a kilowatt-hour; for the next

50 kw.-hr., 10 cents; for the next 100 kw.-hr. 9½ cents, and so on in descending ratio to 6 cents for all energy in excess of 1,000 kw.-hr. The present rate, fixed two years ago, is 11 cents a kilowatt-hour.

Engineering Index Extended.—Extension of the old "Engineering Index" supplied by the American Society of Mechanical Engineers has been undertaken by that society, which announces that its new "Weekly Engineering Index Service" is now "in full swing." More than seventeen hundred publications are reviewed by this service, each article is briefly described, and the resultant notes are classified under thirteen subject headings, printed on index cards and sent to subscribers. Under the classification "Electrical" there are eight subdivisions. Major Carlos de Zafra, 29 West Thirty-ninth Street, New York, is the director of the Engineering Index Service.

Connecticut Light & Power Engineers Remain at Waterbury.—Through a misunderstanding it was announced in the Electrical World for March 31 that the engineering department of the Connecticut Light & Power Company was to be transferred on April 1 to Hartford, with the sales organization, including merchandise sales and advertising. C. L. Campbell, treasurer, informs the Electrical World that the engineering department still remains in Waterbury under the general direction of Irvin W. Day, vice-president in charge of engineering and operations. The sales organization has moved to 36 Pearl Street, Hartford, being under the direction of R. H. Knowlton, vice-president in charge of sales. The Hartford office has been for the past year and a half headquarters of the president, treasurer and financial interests of this company and the other companies controlled by the Connecticut Electric Service Company.

San Joaquin Power Drops Small Hydro Filing.—In connection with certain group filings on prospective hydro-electric sites in the mountain area several years ago the San Joaquin Light & Power Corporation, Fresno, Calif., filed on Whisky Creek, a tributary of the San Joaquin River in the Big Creek region. The site is small and capable only of a 2,000-hp. development as a stream-flow plant. When notice was received that hearing on the application had been set for March 27 the company decided to relinquish its filing as the development would not be undertaken for many years, if ever, and the cost of the plant would be high and its capacity small. At the time the application was withdrawn the company notified the Division of Water Rights that if future power demands should justify it the company would refile its application. Withdrawal of the application gave rise to erroneous newspaper stories that the company had dropped its whole San Joaquin and Kings River hydro-electric development plans.

# Commission Rulings

Purchase of Controlling Interest by Non-Residents.—The Public Service Commission of Pennsylvania held, in adjudicating a complaint brought by the Borough of Brookville against the Solar Electric Company and the Penn Public Service Corporation, that no violation of the law is involved in the purchase of the stock of an electric company by a non-resident in the interest of a holding company which owns another electric company operating in the state, although the commission had refused to approve the purchase of the stock of the first company by the one last mentioned and had approved the purchase or condemnation of its works by the complainant borough.

Indiana Commission Orders Costs of Company Audits, Appraisals and Attorneys' Fees Charged Against Net Income.—A blow at an alleged practice by Indiana utilities of charging to operating expenses large sums incurred by audits, appraisals and attorney fees has been struck by the Indiana Public Service Commission, which has ordered that in the future such expenditures be made from net income. The commissioners declared that the new rule will save utility patrons approximately $1,000,000 a year. According to Commissioner Calvin McIntosh, the resolution is the result of a hearing he conducted about a month ago in which an increase in rates was sought. He presented figures to show that attorneys' fees charged in connection with the hearing, which lasted only about one day, amounted to $3,000 for one firm, $750 for another and $350 for a third. In addition, he said that, although appraisals and audits of the property and books were made by the Public Service Commission engineers and acountants, owners of the company paid $5,000 for an appraisal to one commercial engineer and $500 to another and that $750 was paid by the company for a separate audit of the books. The commission admits that the new ruling is a departure from previous practice in Indiana and other states.

Electric Utility Must, Within Reasonable Limitations, Serve All in Its Territory Who Apply.—In granting a petition for an order requiring the Mountain States Power Company to extend its line to serve would-be customers, the Montana Public Service Commission said: "In 1926 we approved certain regulations governing rural extensions of this company. In the instant proceeding, however, the company has waived in its own evidence a strict adherence to these regulations, and in consequence of its own waiver we see no reason for giving such regulations any force or effect in this case. The subject of rural extensions for public utilities has not received careful consideration in Montana up to this time. Undoubtedly the time is not far off when the subject must be developed by appropriate investigation and some fundamental regulations established, but in the meantime it must be understood that each case is to be determined upon its own facts and the decision herein is to furnish no precedent in other cases—and, of course, it goes without saying that fair rates cannot be promulgated until after actual operation of the extension for a period of at least one year. It is the principal characteristic of commission regulation of rates that response may be made promptly to varying conditions and new circumstances. We have given this case unusual consideration owing to the very important questions presented. We fully appreciate the limitations on the exercise of power which enforces the expenditure of the money of the utility in such a way as amounts to a taking of private property. We appreciate that we may not assume the role of managers and require such property to be used in a service to which the owner has not voluntarily dedicated it. But since it seems certain that the territory is within defendants' profession of service, it is defendants' duty within reasonable limitations to serve all in such territory who apply."

# Recent Court Decisions

City Ordered to Pay for Forced Removal of Line Leased by It to Company.—A suit in the Kansas Supreme Court—Electric Service Company vs. City of Mullinville—concerned a case in which the city had constructed a transmission line for the purpose of supplying its inhabitants with electrical energy and leased it to the company for operation for a net rental sufficient to pay interest on the bonds. The lease provided that the company should maintain the transmission line in good operating condition. The line was constructed on a public highway and the board of county commissioners, desiring to widen the highway, ordered the line removed. A dispute arose over the expense of removing and rebuilding the line. The court determined that it should be borne by the city. (262 Pac. 536.)*

Legality of Sub-Metering by Landlord Upheld.—In the Cuyahoga County (Ohio) Court of Appeals one Jonas brought suit against the Swetland Company, owner of an office building, because that company bought electricity from an illuminating company at a basis of about $115 or $120 a month and charged its customers, particularly the plaintiff, a tenant, about $300 a month. The tenant contended that the defendant, not being a public utility corporation, could not sell light and power to its customers; that it was charging for the service furnished by the illuminating company, and that, therefore, its charge was illegal and it should be enjoined from collecting its bill. In holding that the owner of the building had the right to sell light, power and heat to its tenants, the court said in part: "It surely cannot be possible that a utility company furnishing light, power and heat must make a separate contract with every tenant in a big office building. A thing of that sort would lead to confusion and trouble that surely would warrant the utility company in making a contract with the owners of the building at a wholesale price, who in turn may retail it out to the various customers and tenants. Whether or not the price which they get is a proper price is not for the court to say. We do not think that the building company is prohibited from furnishing light, power and heat to its tenants. On the contrary, we think that it might be its duty to do so. . . . We think that it is a matter of contract between the tenant and the owners of the building as to the price they pay for it; that it is not *ultra vires*, and it is not against public policy that such contract should be made."

# News About Men of the Industry

### *J. G. Holtzclaw President of Southwestern Division*

J. G. Holtzclaw, who was made president of the Southwestern Division of the National Electric Light Association at the recent convention in Biloxi, Miss., as announced in the April 7 issue of the ELECTRICAL WORLD, has been identified with the Stone & Webster interests for twenty years. He was affiliated with the Savannah (Ga.) Electric Company at first, but later he removed to Pensacola and became chief executive of the electric light and power and traction properties in that city. Three years ago, when the transfer of A. F. Townsend to Aurora, Ill., left vacant the office of general manager of the Eastern Texas Electric Company at Beaumont, Mr. Holtzclaw was selected for the position. In 1926 the Gulf States Utilities Company was organized to take over the Beaumont properties, which are still under the executive management of Stone & Webster. Mr. Holtzclaw is a native of Georgia.

*J. G. Holtzclaw*

---

**D. E. KINNEAR** has been appointed secretary of the Maryland Utilities Association to succeed the late G. S. Williams.

**THOMAS N. MCCARTER**, president of the Public Service Corporation of New Jersey, has been elected a member of the board of directors of the Philadelphia Electric Company.

**O. H. MANN** is now electrical superintendent in the Hudson district of the New York Power & Light Corporation. Mr. Mann was for several years a member of the operating force located at the Rotterdam substation.

**H. S. KILBY**, who has been in charge of the power and railway systems of the Missouri Power & Light Company at Jefferson City for the past eight years, has been appointed general manager of the Kansas Power Company, which is affiliated with the Missouri Power & Light Company, with headquarters at Salina, Kan. Mr. Kilby will have supervision of the power plants and service in 96 communities and cities in central Kansas. He has been associated with the Missouri Power & Light and affiliated companies for fifteen years.

**W. E. DICKERSON**, formerly manager of the Central Power & Light Company at Victoria, Tex., has been appointed manager of the recently organized department of industrial development.

**R. O. LOOMIS**, formerly distribution engineer of the Alabama Power Company's southeast division, Eufaula, has been transferred to Tuscaloosa in the capacity of district superintendent.

**WILLIAM G. HICKLING** has been appointed superintendent of the construction and engineering department of the Associated Gas & Electric System at Johnstown, Pa., to succeed P. H. Harris, who has assumed new duties.

**PROF. DR. C. RAMSAUER**, director of the Physical Institute of the Technical High School of Dantzig, Germany, has been appointed head of the new research laboratory which the Allgemeine Elektricitäts Gesellschaft is establishing in Berlin, Germany.

**P. A. MAXIMOV**, president of the Soviet Electrotechnical Trust, has arrived in this country, accompanied by B. I. Bukhovtsev, production manager of the trust, to make a study of the electrical industry in this country. The introduction of electrical power in industry, transportation and for lighting purposes is proceeding now on a scale never before known in Russia, according to Mr. Maximov. He expects to stay in this country about six weeks. Together with Mr. Bukhovtsev he will visit Schenectady, Boston, Chicago, Milwaukee and other industrial centers.

**GEORGE B. TRIPP**, for many years engaged in the executive management and operation of electric light and power, street railway and gas companies, has affiliated himself with Glidden, Morris & Company, investment bankers, New York. For the past three years he has directed the operation of the natural gas property of the Huntington Development & Gas Company, Huntington, W. Va., a subsidiary of the Columbia Gas & Electric Corporation. In the course of his public utility career he has been connected with the Cleveland Electric Illuminating Company in various capacities, with the Colorado Springs Electric Company as general manager, with other electric companies in Colorado, with the Harrisburg (Pa.) Light & Power Company in the capacity of vice-president and with the United Gas & Electric Engineering Corporation of New York as vice-president. Mr. Tripp was some years ago president of the Pennsylvania Electric Association and also of the Colorado Electric Light, Power and Railway Association.

### *J. E. Montague Doubly Honored*

Joseph E. Montague, vice-president and general manager Niagara Electric Service Corporation, Niagara Falls, N. Y., has been elected president of the company to succeed the late George Urban, Jr. He was also elected a director of the Niagara Falls Power Company at a meeting of the stockholders to succeed the late C. P. Hugo Schoellkopf. Mr. Montague has been in charge of the operations of the Niagara Electric Service Corporation since 1903 and the growth the company attained under his direction has been the subject of frequent comment in the electrical world. In the light of these achievements the promotion of Mr. Montague as the official head of the corporation naturally followed.

*J. E. Montague*

Mr. Montague has long been identified with various enterprises on the Niagara frontier and he occupies a prominent position in the business and social circles of that district.

---

**THOMAS GRAY**, manager of the Brighton district of the Public Service Company of Colorado, has been transferred to the Alamosa district and **G. C. CHIPMAN**, manager of the Berthoud district, has been named to succeed Mr. Gray at Brighton.

**HENRY A. SUPRENANT**, formerly in charge of the Vernon plant of the New England Power System, has been appointed supervisor of operations of the company's western division with headquarters at Shelburne Falls.

**FRANCIS D. WYATT**, formerly electrical engineer of the Columbia Engineering & Management Corporation, is now chief engineer of the Cutter Company, Philadelphia. Mr. Wyatt had been associated with the Columbia system since 1916, having joined the Union Gas & Electric Company, Cincinnati, in that year in the capacity of electrical engineer. His early experience following graduation from Ohio State University was with the Doherty Operating Company, where he remained three years, and with the electric research laboratory of the National Cash Register Company, the connection he severed to affiliate himself with the Union Gas & Electric Company.

Ellis A. Ballard has been elected a director of the Electric Storage Battery Company to fill the vacancy caused by the death of J. R. McAllister.

Max W. Babb, vice-president and general attorney of the Allis-Chalmers Manufacturing Company, has been elected a director to succeed the late Charles F. Pfister.

Justin G. Smeby has been recently appointed welding engineer at the South Philadelphia works of the Westinghouse Electric & Manufacturing Company. He has been connected with the Westinghouse company since 1922.

Wylie Brown, president of the British American Metals Company, Plainfield, N. J., and vice-president of the American Copper Products Corporation, Elizabeth, N. J., has been elected president of the Habirshaw Cable & Wire Corporation, with plants at Yonkers and Nappingham, N. Y., and Bridgeport, Conn.

Ralph W. Carpenter, for the past thirteen years local manager of the Idaho Power Company at Nampa and Emmett, Idaho, has been appointed manager of its newly created Jerome division with headquarters at Jerome. Before entering the public utility field he was engaged in the contracting branch of the electrical industry in Boise.

Oliver M. Spratt, who some ten years ago was associated with the Foshay interests, has recently rejoined the Foshay Company in the capacity of assistant to the president. It was in 1916 that Mr. Spratt became local manager of the Baxter Light & Water Company, Baxter Springs, Kan., for the Foshay Company, but when the plant was sold three years later he continued to manage a private business which he had been carrying on in addition to his duties with the Baxter Springs property.

William Johnston, Jr. has been appointed vice-president of the Twin State Gas & Electric Company, Vermont Hydro-Electric Corporation, Rutland (Vt.) Railway, Light & Power Company and Middlebury (Vt.) Electric Light Company, with headquarters in Boston, Mass. Mr. Johnston joined the Twin State organization in 1919 as traveling auditor, and since 1922 has been auditor of the Twin State and associated utilities. He will have general executive responsibilities in his new post.

Leon E. Seekins has been appointed manager of the Lowell (Mass.) Electric Light Corporation, succeeding John A. Hunnewell, who recently was elected president of the company following its acquisition by the New England Power Association. Mr. Seekins was formerly employed by the Lowell company in the power sales engineering and other departments, and in 1924 was made assistant to the manager. After twelve years' service with the company he was appointed manager of the Cape Breton Electric Company, Ltd., Sidney, N. S., whence he returned to Lowell.

## *H. L. Masser Vice-President of Los Angeles Utility*

Harry L. Masser, gas engineer of the Los Angeles Gas & Electric Corporation since 1924, has been made vice-president and executive engineer of the company. Los Angeles is Mr. Masser's native city and the University of California his alma mater. His early experience was with the Southern California Gas Company and the Midwest Gas Company, connections which covered a period of three years. He served in the engineering branch of the United States Navy during the war and spent five years with the engineering department of the Railroad Commission of California. He severed his affiliation with the commission in 1924 to become gas engineer for the Los Angeles corporation. In his new position Mr. Masser will be in charge of all production, distribution, construction and operation, both gas and electric.

*H. L. Masser*

James R. Werth, formerly head of the power bureau of the Florida Power & Light Company, Miami, has been appointed head of the new-business division of that company. Mr. Werth's past connections include the Lynchburg (Va.) Traction & Light Company, the H. M. Byllesby Company, the West Penn Power Company and the General Electric Company.

Charles C. Hellmers has been appointed manager of the Lincoln district of the Iowa-Nebraska Light & Power Company. A native of St. Louis, Mo., Mr. Hellmers became interested in the utility business early in life, organizing and developing the group of electric properties in northwestern Missouri known as the Maryville Electric Light & Power Company. After the Iowa-Nebraska interests took over these properties he was advanced to an executive position in the general offices.

L. F. Sandford, until recently manager of the new-business department of the Southwest Power Company at Fayetteville, Ark., has become sales manager for the Arkansas Utilities Company at Helena.

G. M. Nash, formerly service supervisor of the Poughkeepsie district of the Central Hudson Gas & Electric Company, has been appointed district operating supervisor at Beacon, N. Y., to succeed G. D. Horne, who has assumed new duties in Poughkeepsie.

Thomas S. Craig, formerly connected with the Jones & Laughlin Steel Company and more recently with the Power Specialty Company, has joined the sales department of the Elmira Water, Light & Railroad Company, Elmira, N. Y. Mr. Craig received his technical education at the Carnegie Institute of Technology and at the Massachusetts Institute of Technology.

N. R. Beagle, assistant chief engineer of the North American Light & Power Company, with headquarters in Peoria, Ill., has been appointed superintendent of the Jefferson City offices of the Missouri Power & Light Company to succeed H. S. Kilby, who has been in charge of the power and street car systems in that city for the past eight years. Mr. Beagle has been connected with the North American company for a number of years.

R. W. Warner, formerly connected with the substation engineering department of the Kansas City Power & Light Company, Kansas City, Mo., is now identified with the overhead engineering department of that company. Mr. Warner was previously connected with the General Electric Company at Schenectady, where he engaged in switchboard work. At first he worked on transmission lines for the Kansas City company, but more recently he has done some special street lighting work.

## Obituary

John J. Murphy, president of the Electrical Construction & Machinery Company of Rock Island, Ill., died in that city April 4 in his fifty-ninth year. Mr. Murphy was a member of the A.I.E.E.

Robert Pfeil, a director of the Siemens & Halske Company, Berlin, died recently in his sixty-fourth year. A native of Wiesbaden, Dr. Pfeil was educated at the Technical High Schools of Karlsruhe and Brunswick. He had been associated with the Siemens & Halske organization since 1892.

Dr. Theodore W. Richards of the chemistry department, Harvard University, a Nobel prize winner and distinguished authority in the field of atomic weight research, died at Cambridge, Mass., April 2. He was a profound investigator in physical chemistry and a member of many learned societies.

# Financial and Statistical News

## *Four Per Cent Coupons Appear Stocks Firm and Active*

THE fact that 4 per cent utility bond issues have been predicted for some time and that they are entirely in line with the trend does not detract from the interest shown in the first one to make its appearance, the $35,000,000 issue of the Cincinnati Gas & Electric Company, which was marketed this week. The rapidity with which this issue was absorbed may be regarded as a further indication of the trend. A gradual appreciation of the merits of utility securities, the widening of the legal market for these issues, the current trend of money rates in general—all these factors are working toward lower coupons in connection with new utility issues, and the cause for surprise is not so much the reduction in yield as the fact that utility bond rates are still considerably above those of comparable issues; those, for example, of the railroads. A new level has been established this week, but the trend is still toward lower levels.

Power and light company common stocks continue their upward trend. Outstanding advances were made by American Gas & Electric, which reached 140; Brooklyn Edison, which gained ten points, to 251; Middle West Utilities, to 143, etc. Preferred stocks continue firm with prices somewhat higher for the week.

## Three New Preferred Issues Offered

During the week ended April 12 three new offerings of preferred stock were made. The American Electric Power Corporation issued 35,000 shares of $6 preferred stock at $93.50 a share and accrued dividends, to yield over 6.40 per cent. With the purpose of refunding short-term loans outstanding and for other corporate purposes the New England Public Service Company issued 45,000 shares of $6 preferred stock at $97.50 per share and accrued dividends to yield over 6.15 per cent. The Iowa Public Service Company issued 5,000 shares of $6 cumulative first preferred stock, the price being $100 per share and accrued dividend, to yield 6 per cent.

First mortgage gold bonds, series A, of the Cincinnati Gas & Electric Company were offered at 92½ and accrued interest, to yield 4.40 per cent, a piece of financing involving a total of $35,000,000. The Cincinnati Gas & Electric Company will presently effect a consolidation with the Columbia Power Company and thereafter will acquire all the physical properties of the Union Gas & Electric Company. These bonds are being issued incident to this consolidation, in consummation of which all of the previous funded debt of the Cincinnati Gas & Electric Company will be retired, its capital stock will be exchanged share for share for 5 per cent preferred stock of the consolidated company, the preferred stock of the Union Gas & Electric Company will be retired, and capital funds will be provided for other corporate purposes.

The Queens Borough Gas & Electric Company made an offering of 4½ per cent refunding mortgage gold bonds totaling $4,000,000 at 100 and accrued interest.

The Super-Power Company of Illinois made an offering of 4½ per cent gold bonds, due March 1, 1968, to the amount of $10,000,000, the price being 98½ and interest.

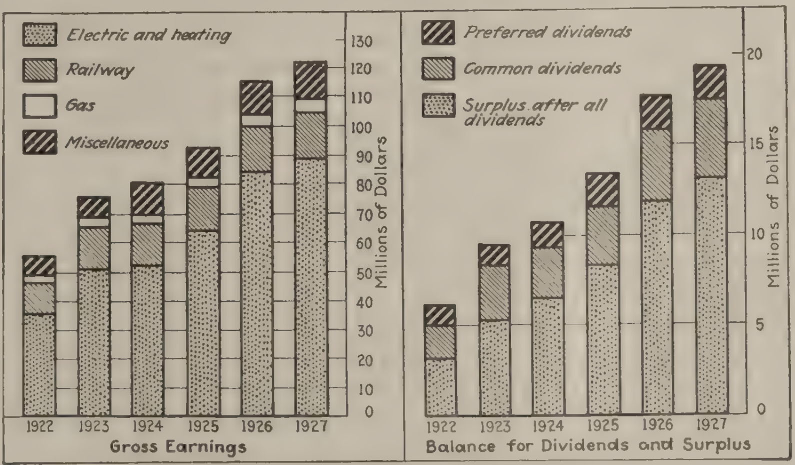
Two foreign loans were floated during the week, an issue involving 100,000 shares of the Swiss-American Electric Company in the form of $6 cumulative preferred stock and an issue of first mortgage sinking fund gold bonds of the Electric Power Corporation (Germany), involving $5,000,000.

## New England Public Service Gross up $744,177

The New England Public Service Company in its annual report for 1927 shows total net income for the year of $1,646,577. A consolidated earnings statement of the subsidiaries of the New England Public Service Company for the year shows total gross earnings of $13,569,943, an increase of $744,177 over the year 1926.

After payment of all expenses, interest and prior lien and preferred dividends there was available for dividends on the 286,889 shares of common stock outstanding Dec. 31, 1927, $1,201,425. This represents the combined surplus earnings of the New England Public Service Company and its subsidiary companies and is equivalent to $4.18 a share. The total number of stockholders of all subsidiary operating companies was 22,725.

## North American's Net Revenue Is Up 10.47 per Cent



*Earnings have doubled in past six years*

AN INCREASE in gross earnings of 5.45 per cent and a growth in net of 10.47 per cent are disclosed in the 1927 annual report of the North American Company group. The operating ratio, or the ratio between gross earnings and operating costs, maintenance and taxes, showed a decided improvement—from 55.57 per cent in 1926 to 53.46 per cent last year. Depreciation reserves exceeded 10 per cent of gross.

After all deductions, the balance for dividends and surplus was $19,254,647, of which $1,820,022 was used for dividends on parent company preferred stock. There remained $17,434,625 after all preferred dividends, which is an increase of 10.74 per cent over 1926. This is equivalent to $4.06 per share, against $3.85 in 1926 and $3.12 in 1925. After all dividends on preferred and common stocks of North American Company and charges of $3,881,478, consisting principally of writing off unamortized discount and expense and premiums on bonds retired, undivided profits increased by $9,211,375, or 21.86 per cent. At the end of 1927 undivided profits amounted to $51,358,612, in addition to $23,821,632 capital surplus.

The North American Company's electric output of 5,003,332,121 kw.-hr. in 1927 was 5.25 per cent above the 1926 total, and the gas output increased 14.42 per cent. The number of electric customers increased 5.82 per cent, to 993,332.

## American Power & Light Acquires Montana Power

Acquisition of the Montana Power Company by the American Power & Light Company, which is supervised by the Electric Bond & Share Company, is stated to be based on exchange of Montana common stock for a new $5 preferred issue, series A, of the purchasing company, one for two. A banking syndicate has made an offer to purchase at $83 a share, plus accrued dividends from April 1, new preferred stock of American Power & Light, which Montana Power common shareholders may have received in exchange and wish to sell, up to May 2. This places a value of $166 a share on the Montana Power common, or of $82,391,278 on the 496,333 shares of stock outstanding.

The new $5 preferred issue into which Montana Power common is to be converted will be entitled to cumulative quarterly dividends at the rate of $2.50 a share for the remainder of 1928, to $3 for 1929, to $3.50 for 1930, $4 for 1931 and $5 thereafter. This issue has the same standing as the $6 preferred stock except as to dividend rates and call price.

The plan is subject, of course, to the approval of the Montana Power Company shareholders, who will meet April 24.

**Illinois Utility Increases Stock.**—Stockholders of the Central Illinois Public Service Company approved an increase in the authorized $6 cumulative preferred stock to 350,000 shares (no par value) from 225,000 shares and in the authorized common stock to 350,000 shares (no par value) from 250,000 shares.

**Canadian Stockholders Offered Rights.**—A resolution of the board of directors of the Canada Northern Power Corporation, Ltd., passed March 23 authorized the issuance from the treasury of 15,000 shares of the no-par value common stock to be offered to holders of the same class of stock of record March 31, at $50 per share, on the basis of one new share for each four shares held.

## Central Maine Power Issues Good Report

The Central Maine Power Company in its annual report for 1927 shows gross earnings for the year of $5,784,988, an increase of 9 per cent over the previous year. Net earnings for the same period showed an increase of 25 per cent. Sales of electricity were 36,576,821 kw.-hr. in excess of the previous year. Of this increase 82 per cent resulted from actual growth of the company, with the remaining 18 per cent the result of companies acquired during the year. Merchandise sales for the same period were $80,000 greater than in 1926.

The report shows that visible progress has been made within its territory toward industrial expansion with twelve new industries secured and eleven idle industries rehabilitated. The company has also assisted 28 industries to expand. Approximately 650 farm customers were added last year, so that now about 14.7 per cent of the total farms within the territory are electrified. This is believed to be the high-

est percentage of farms served by any large company east of the Mississippi River.

North American Company to Decrease Number of Directors.—Stockholders of the North American Company will vote April 25 on approving the recommendation of the board that the number of directors be decreased from fifteen to twelve.

Russian Statistics.—Recent Russian economic statistics are contained in an 80-page handbook issued by the Amtorg Trading Corporation. It contains data on the electrical and other industries, agriculture, foreign and domestic trade, transportation, communication, finance, labor, natural resources and patents.

Brown, Boveri to Increase Dividend and Capital.—The directors of Brown, Boveri & Company, Mannheim, Germany, have decided upon a dividend of 9 per cent for 1927, against 8 per cent in the previous year, the net profit being 1,470,000 marks, in comparison with 1,030,000 marks in the previous year. The capital is to be increased from 15,000,000 to 25,000,000 marks. The new shares are to be offered to shareholders in the proportion of three to two. The company is said to have begun the current year with a good order book.

Survey of Kentucky Industries Attracts Attention.—An industrial survey of Kentucky has been completed by the Associated Industries of Kentucky. This survey includes a careful study for each of the 120 counties in the state, in respect to geological formation, soil, water supply, industries, transportation facilities, highways, educational opportunities and other factors which might attract industries or investment of capital. According to the Secretary of the Associated Industries of Kentucky this survey not only has served the purpose for which it was intended but has also attracted inquiries from organizations in several other states interested in similar undertakings. A limited number of copies of the survey are said to be available for general distribution from the office of the association in the Kenyon Building, Louisville, Ky.

Massachusetts Utility Votes Extra Dividend.—The Holyoke (Mass.) Water Power Company voted an extra dividend of 3 per cent on the capital stock.

# Rate of Production Up 4.4 per Cent During First Quarter

THE rate of general production during the first quarter of 1928 was on an average about 4.4 per cent over that reported for the same period during 1927, as indicated by the consumption of electrical energy by some 3,000 large manufacturing plants scattered throughout the nation. As has been the case during the last five years, the peak of operations in American manufacturing plants as a whole this year was reached in February, the March rate of production, after correction is made for the number of working days, being about 7.4 per cent under February. The March activity, however, was still about 1.2 per cent over March of last year. It would appear, therefore, that American industry as a whole is following very closely the trend of last year, but on a slightly higher plane. All of the industrial groups reported a seasonal drop in rate of operations under those of February. Nine of the industrial groups reported March operations over those of March last year, and only two—textiles and rolling mills and steel plants—reported a rate of operations under that reported for March of last year.

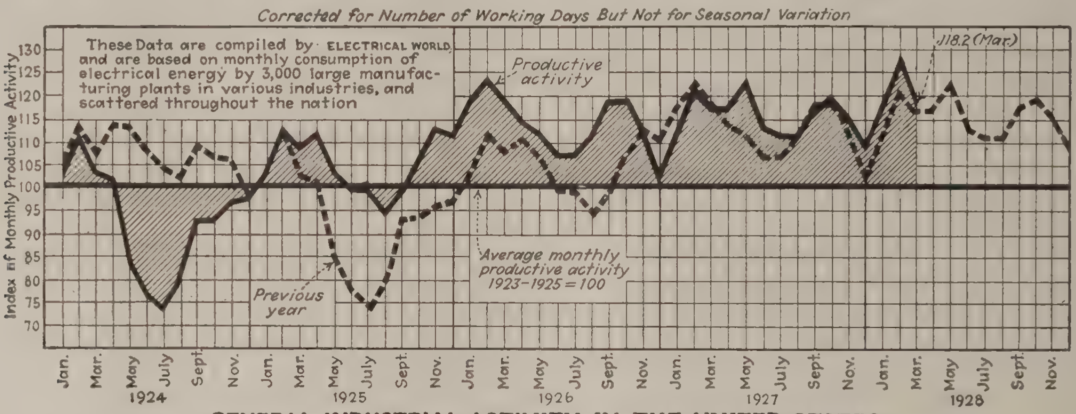
The index of activity in the manufacturing plants of the nation based on consumption of electrical energy stands at 118.2 for March, as against 127.7 for February, after adjustments are made for the number of working days in the two months. Comparative indexes of productive activity, referred to the average activity for the period 1923-25 as 100 and adjusted for number of working days, is as follows:

| | |
|---|---|
| March, 1928 | 118.2 |
| February, 1928 | 127.7 |
| March, 1927 | 116.8 |
| Average first quarter 1928 | 121.4 |
| Average first quarter 1927 | 116.3 |

The rate of operations in the rolling mills and steel plants was quite significant, standing at 6.8 per cent under February, bringing the rate of operations to a point about 1 per cent under March last year. A decreased rate of operations was normal during March, but the drop this year was more than was to be expected, based upon the reports for past years. Last year the decline from February to March was about 1 per cent. The ferrous and nonferrous metal working plants also recorded a material drop under February, but the current March activity was still above that of March, 1927.

A material decrease in the rate of production in the automobile manufacturing industry, including the manufacture of equipment and replacement parts, seems to have been recorded during March. The March activity was 8.4 per cent under February, but was still about 15.2 per cent above March last year.

March rate of operations in the textile industry was some 8.2 per cent under March last year and about on the same level as for March, 1926. Operations in the textile industry of the nation have been under those of the same month of the previous year ever since last October.



Corrected for Number of Working Days But Not for Seasonal Variation

These Data are compiled by ELECTRICAL WORLD and are based on monthly consumption of electrical energy by 3,000 large manufacturing plants in various industries, and scattered throughout the nation

## Sell Additional Wiring

*N.E.L.A. Issues Serial Report to Aid Central Station Company in Conducting a Campaign for Adequate Wiring*

THE wiring committee of the Commercial National Section of the National Electric Light Association has issued a serial report dated March, 1928, entitled "Sell Additional Wiring." The wiring committee believes that it is essential that immediate steps be taken in every community to promote the sale of additional wiring for, as was expressed in a recent editorial, "the inadequacy of present house-wiring installations interposes a baffling barrier to the sale of electrical equipment." The committee further states that some successful sales campaigns have already been conducted and this report is presented as a summation of past experience and an urge and guide for immediate action in every community in the land.

In planning the sale of additional wiring the committee in its report offers the following eight factors with a complete discussion of each one: (1) Knowledge of the market. (2) Co-operation with local electrical interests. (3) Determination of a definite sales policy. (4) Development of an adequate publicity program. (5) Organization and training of sales force. (6) Directing of activity to reach all prospects. (7) Analysis of results as a guide for further activities. (8) Report to wiring committee. N. C. Huse, the Philadelphia Electric Company, Philadelphia, is chairman.

In its conclusion the report cites the past restrictive influences, gives the reasons for the present hopefulness and in referring to the need for action states that there is but one sure way to get a job done and that is to do it. "No matter what national plans may be made for co-operative industry action," states the report, "the central-station company can in no way evade direct responsibility for initiative in reaching the tremendous market which is now unattainable due to the inadequacy of the wiring connections on the customers' property at the ends of our distribution systems." The wiring committee states that it is anxious to furnish all assistance possible to central-station companies contemplating definite action and will welcome direct inquiries for more detailed information in expanding items contained in the report or for suggested plans to meet specific local conditions.

## Orders and Billings for Electrical Goods

Some of the data on orders and billings collected by the National Electrical Manufacturers' Association are shown in the form of graphs in the accompanying illustrations. Complete data for 1927 are given in every case. Statistics on the electrical manufacturing industry to help in guiding its course are still meager, although the past year has shown some improvement. A marketing plan is dependent on a proper conception of the program of the industry. Facts and conditions must be known in order to base a correct premise. The data now being gathered are a great help toward obtaining the necessary facts regarding the industry. Additional graphs covering other products will appear in succeeding issues.

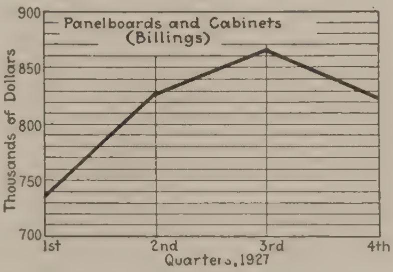
(Not included in switchboards)



## N.E.M.A. Organizes Electric Furnace Section

Manufacturers of resistance type electric furnaces have been organized in the electric furnace section of the National Electrical Manufacturers' Association. That section begins its existence with a membership comprising about 90 per cent of the total output of the product. William Little, Hoskins Manufacturing Company, is chairman and R. F. Benzinger, Electric Furnace Company, is secretary of the section. The companies in the section and their representatives are Electric Furnace Company, Salem, Ohio, R. F. Benzinger and F. T. Cope; Hevi-Duty Electric Company, Milwaukee, E. L. Smalley; Geo. J. Hagan Company, Pittsburgh, R. E. Talley; Holcroft & Company, Detroit, C. Holcroft; Hoskins Manufacturing Company, Detroit, W. Little, and Westinghouse Electric & Manufacturing Company, Mansfield, Ohio, T. C. Kelley.

One of the first acts of the new section was to decide on the collection of statistics giving orders entered for electric furnaces in units, kilowatts and dollars and divided into two groups of 100 kw. and below and over 100 kw. The members of the section are very optimistic for the future of the electric furnace business, some believing that in the course of time the electric furnace load will exceed the motor load on central-station lines. The section is also looking to the other electrical apparatus manufacturers to help promote the more general use of electric heat in industry. It is claimed that every 100 kw. of electric furnaces requires the utilities to expend $15,000 for generating and transmission equipment, exclusive of land and buildings.

*Flexible Cord*

Data Supplied by National Electrical Manufacturers' Association

# Market Conditions

IN NEW ENGLAND motor sales continue to be active and reached a volume of over $60,000 last week. Textile and leather plants were active buyers. Anticipation of the opening up of early line extensions in the northern districts is awakening interest in buying. An upward trend in market activity is reported in the Eastern district with central-station companies and industrial plants sharing about equally in the demand. An order for $330,000 worth of substation apparatus was placed by a New York company and an order for similar equipment was reported in New Jersey. A paper mill at Erie, Pa., bought $40,000 worth of motors and control apparatus.

Two 60,000-kw. turbo-generator units amounting to approximately $1,500,000 were purchased by a Carolina power company. Another order for about $110,000 worth of motors, oil circuit breakers and switching equipment was received from a central-station company in Alabama. Industrial plants in the Southeast are less active but inquiries are numerous. A slight improvement is seen in conditions in the St. Louis district. The volume of business in the Middle West has increased and utility companies are busy with construction work. A large company's purchases are averaging $95,000 per day. On the Pacific Coast power company buying was active and included diversified equipment and supplies. Pole orders were good, and motor sales were reported excellent.

## *Market Trends Upward in Eastern District*

Each week is developing improved market activity in the Eastern district with central-station companies and industrial plants sharing about equally in the demand. According to a large manufacturer the first quarter of the year shows an increase of 4 per cent in central-station orders over the corresponding period of last year, while industrial business has run close to 6 per cent below that of 1927 in the same quarter. This statement is quite typical of general findings in the trade and with increased inquiries now ensuing from industrial plants, it is expected that the slight deficiency in the quota soon will be made up. The outlook continues good and there is every indication of sizable commitments for the next few months.

Central stations are in the market for substation equipment and are also making purchases of wire and cable and line apparatus. A New York utility has placed an order for transformers, oil circuit breakers, switching equipment and auxiliary apparatus for four substations, totaling about $330,000. A New Jersey central-station company has been making contracts for similar apparatus for new substations and is expected to place further orders at an early date. A leading manufacturer of wire and cables reports marked improvement in the demand from power companies, with utilities in the New York zone leading in volume of orders. A metropolitan central-station company has placed an order for paper-covered cable totaling $300,000. Industrial interests also are purchasing sizable requirements of wire and cables, with inquiries indicating a continuance of the demand from that quarter.

A paper mill at Erie, Pa., has contracted for equipment for a paper machine installation costing about $40,000. Other business of this character is now maturing and early orders are anticipated. The demand from iron and steel mills, metal-working plants, automobile plants, leather factories and textile mills is holding up well and sizable transactions, particularly in connection with motors and accessory equipment, are being made. Municipal and other public work show improvement, both with regard to volume of bids asked and actual contracts.

The Philadelphia market is more active. Central stations are making purchases of equipment for substation installations and transmission lines, the Eastern Pennsylvania power companies being particularly busy in the latter connection. Industrial account begins to show improvement. There is a healthy tone to the present demand for motors, control devices, switchboard panels and instruments, and commitments are now being made with less hesitancy. Metal-working plants and textile mills are leading buyers.

Current construction operations in the Eastern district include the following: New York has appropriated $500,000 for the construction of a municipal airport on Barren Island, also a fund of $300,000 for a new fire alarm system. The Todd Shipyards Corporation will increase its plant in Brooklyn, to cost $2,000,000. The Bayonne Steel Ceiling Company plans a plant at Long Island City, to cost $100,000. The Stauffer Chemical Company, New York, plans a plant near Roanoke, Va., to cost $250,000. Tottenville, S. I., and Millville, N. J., plan ornamental lighting systems. Benjamin Moore & Company, Newark, N. J., plans an addition to its paint factory, to cost $175,000. The Reading Coal & Iron Company, Philadelphia, Pa., plans electrification of its coal mines at Hazleton, Wilkes-Barre and vicinity. The Metropolitan Edison Company has secured permission to take over eleven light and power companies in Chester, Adams, Dauphin, Berks, Lehigh and Lebanon Counties for a price of $2,401,000, and will extend transmission lines. The Suburban Light & Power Company, Cambridge, Md., recently formed, has secured permission to build transmission lines in St. Mary's, Charles and Prince George's Counties, to cost $100,000; service will be obtained from the Potomac Electric Power Company, which will extend its system. The Bureau of Standards, Washington, D. C., will receive bids until April 27, for equipment for power plant. The Bureau of Yards and Docks, Navy Department, Washington, D. C., is asking bids (no closing date stated) for a refrigerating plant for Mare Island Navy Yard (Specification 5583.)

## *Metal Markets Quieter—Prices Slightly Lower*

Sales of lead and zinc were in fair volume in the non-ferrous metal market. No important price changes were registered during the week with the exception of tin, which dropped almost 2 cents per pound. Copper has entered another period of quiet such as characterized the early weeks of the year, with the same conditions predominating; that is, the primary producers are firm at one price, with only an occasional sale, while concessions are offered by others who make it a practice to sell an appreciable tonnage every week.

NEW YORK METAL MARKET PRICES

| | Apr. 4, 1928 Cents per Pound | Apr. 11, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 14.0 | 13 9625 |
| Lead, Am. S. & R. price | 6.10 | 6.10 |
| Antimony............ | 9¾ | 9.625 |
| Nickel, ingot.......... | 35 | 35 |
| Zinc spots............ | 6.075 | 6 075 |
| Tin, Straits.......... | 53¾ | 51.875 |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper wire price April 11, 1928, 16 cents.

## *Large Turbine Units Purchased in Southeast*

The outstanding order placed in the Southeast was for two 60,000-kw. turbo-generators. They were purchased by a Carolina power company at a cost of about $1,500,000. Another outstanding order was for motors, oil circuit breakers and switching equipment amounting to about $110,000 placed by a central-station company in Alabama. A company in Georgia ordered weatherproof copper wire amounting to $22,000 and aluminum cable totaling $5,200, and this same company's creosoted pine pole purchases in the past ten days have totaled $2,900.

Little activity was noted in industrial lines, though inquiries are increasing in number and the amount of industrial expansion projects pending or in the hands of engineers reflects the optimistic tone of business. Municipalities continue to purchase in reasonably satisfactory volume. One Georgia town ordered pole line materials amounting to $2,500 and another ordered one carload of creosoted pile poles.

Construction projects are as follows: The Columbus Electric & Power Company, West Point, Ga., plans a 40,000-hp. hydro-electric power project on the Chattahoochee River, Troup County, to cost $700,000. The Stowe Thread Company, Belmont, N. C., plans a new mill to cost $120,000. The Duke Power Company has approved plans for a steam-operated electric power plant near Mount Holly, N. C., to cost $5,000,000. The Jepson Art Weaving Company, Wadesboro, N. C., plans a textile mill, to cost $150,000.

The Victor Chemical Works, Chicago, plans a plant at West Nashville, Tenn., to cost $1,000,000. Lexington, Va., contemplates a municipal power plant. The Blue Ridge Power Company, Manassas, Va., plans a power plant to cost $80,000. The Mississippi Power Company, Gulfport, Miss., is planning extensions in transmission lines at Burnsville, Plantersville and vicinity. The Southeastern Power & Light Company plans extensions in transmission lines of the recently acquired Edisto Public Service Company, Columbia, S. C.

## *Motor Sales Continue Active in New England District*

General purpose motor sales showed encouraging activity in the New England district. The volume amounted to over $60,000 last week. Buying in lots was noted with textile and leather industries leading. Among the orders reported were several units up to 75 hp. Reorganization and change of factory sites reflect this strong demand.

A slight quickening in the demand for central-station supplies was reported. A prominent light and power company placed an order for cable and wire, to be used for service expansion, amounting to about $50,000. Watt-hour meter and voltage regulator business is active, and several interesting orders for insulators covering a wide area were noted. Anticipation of the opening up of early line extensions in the northern districts is awakening interest in buying.

Construction projects are as follows: Authorization for a new federal post-office for Boston to cost about $4,500,000 is announced. The New England Telephone & Telegraph Company plans to expend $1,250,000 for service expansion. The Holyoke Water Power Company, Holyoke, Mass., has secured permission for a 45,000-hp. hydro-electric plant on the Connecticut River to cost $850,000. The Narragansett Electric Company, Providence, R. I., plans a substation, to cost $35,000. The Connecticut Light & Power Company will add to the street-lighting system at Southington.

## *Slight Improvement Seen in St. Louis Conditions*

Conditions in the St. Louis district seem to be slightly improved. Small motors and transformers moved in good volume. A contract for switching equipment for four towns in the southwestern part of the district was closed at a cost of $15,000. Automatic substation equipment to replace hand-operated apparatus in the suburbs of St. Louis was purchased at a cost of $35,000. Poles, cables and fixtures for a "white way" for a small city in southeast Missouri amounted to $18,000. The installation cost of this apparatus is estimated at $9,000. Refrigerator manufacturers report the demand greater than the supply.

Construction projects are as follows: The White River Power Company, Little Rock, Ark., will build a hydro-electric power plant on the White River, near Cotter, Ark., to cost $1,200,000. The Meeker Advertising Company, Joplin, Mo., plans a two-story factory for novelty manufacture, to cost $100,000. The Chevrolet Motor Company, Detroit, Mich., contemplates an assembling plant at Kansas City, Mo., to cost $500,000. The Quaker Oats Company, Chicago, Ill., plans a plant at St. Joseph, Mo., to cost $2,000,000. The Independent Plumbing & Heating Supply Company, 1119 Chestnut Street, St. Louis, Mo., plans a new plant to cost $125,000. The American Car & Foundry Company plans an addition to its plant at St. Louis, to cost $200,000. The Texas Electric Service Company, Odessa, Tex., plans improvements in its power plant, to cost $75,000.

The Bell Oil & Gas Company, Sweetwater, Tex., plans an oil refining plant, to cost $175,000. The Texas Utilities Company plans extensions in transmission lines at Olton, Tex., and will install a light and power system. The Texas Utilities Company, Plainview, Tex., plans a steam-operated plant in the Panhandle district, to cost $500,000. The Springfield Gas & Electric Company, Springfield, Mo., will install an ornamental lighting system to cost $125,000. Muskogee, Okla., has contracted with the Electric Service Company, for the installation of an ornamental lighting system.

## *Power Company Buying Active on Pacific Coast*

Power company buying on the Pacific Coast has been excellent, including such orders as $95,000 worth of lead cable for the city of Los Angeles, a 200-hp. synchronous motor valued at $3,000, three heavy-duty circuit breakers valued at $5,000, and six voltage regulators valued at $10,000, for the Bay district, and $2,000 worth of rubber covered wire and $4,000 worth of assorted hardware for the Fresno district. Pole orders are good, including $1,500 worth of treated poles for Lompoc, one carload 9-in., 50-ft. treated poles and $2,000 worth of 12-in. stubs for Fresno and two carloads of 5-in., 25-ft. poles for Gilroy.

Street lighting business includes 71 standards and equipment valued at $9,000, for a San Mateo suburb, 62 standards, valued at $2,000, for Sacramento and a $3,000 equipment for a Belmont tract. An interesting inquiry covers the proposed equipment of a Yosemite resort with 3-kw. and 5-kw. 40-gallon tank water heaters and 3-kw. and 5-kw. air heaters. Industrial business includes a 175-hp. synchronous motor, valued at $3,000, for an ice company and a 300-hp. motor, switchboard and accessories, valued at $5,000, for a Hawaiian sugar plantation.

An award was made by the Port of Olympia for $16,000 worth of compressors and refrigeration equipment for a cold storage plant and several awards of equal importance are pending in the Wenatchee and Okanogan districts. The Pacific Power & Light Company at Lewiston, Idaho, plans the immediate expenditure of $90,000 in reconstructing and improving power lines in the Lewiston and Clarkston districts, and the water board of Eugene, Ore., is expected to issue specifications at once for equipment for a power plant to cost about $1,250,000.

Construction projects are as follows: The Douglas Company, Santa Monica, Calif., will build a two-story aircraft manufacturing plant, to cost $100,000. The Southern Colorado Power Company, Pueblo, Colo., plans improvements in power plants and transmission lines to cost $275,000. The Pioneer Sand & Gravel Company, Miles City, Mont., will build an electric-operated sand and gravel-washing plant, to cost $90,000. The Holly Sugar Company plans improvements in its mill at Torrington, Wyo., to cost $200,000. Santa Paula, South Gate, Santa Barbara, and Corona, Calif., plan installation of ornamental lighting systems.

## *Volume of Sales Increases in Middle West*

The volume of business increased somewhat in the Middle West and indications seem to point to a general improvement. Industrial activity is noted and employment has increased considerably. Reports of increased construction and railroad activity are encouraging and these, together with increased sales in the agricultural districts, seem to indicate a recovery from the slight depression noticed recently. The various utility companies are busy with spring construction work and a large amount of rehabilitation and maintenance work is going on, one large utility company's purchases averaging $95,000 a day. Among the interesting orders placed was one for cable valued at $92,000 and several construction orders totaling $100,000. There has been a good demand for transformers, poles, pole line hardware and general distribution equipment. Jobbers' sales have improved somewhat.

Construction projects are as follows: The Bassick Manufacturing Company, Chicago, will build a plant addition to cost $300,000. The Commonwealth Edison Company, Chicago, has filed plans for a substation on North Harding Avenue, to cost $80,000. The Martin-Parry Corporation, Indianapolis, Ind., is considering an addition to its automobile body plant, reported to cost $80,000. The Brown Shoe Company, St. Louis, Mo., plans a three-story factory at Mattoon, Ill., to cost $200,000. The Chevrolet Motor Company, Bay City, Mich., plans a one-story unit to cost $450,000. M. A. Erickson, Rugby Light & Power Company, Rugby, N. D., will make extensions in the power plant at Westhope, N. D. Akron, Ohio, plans installation of an airport lighting system at the municipal landing field. The Union Gas & Electric Company, Cincinnati, Ohio, will build a substation at Harris and Marion Avenues, to cost $35,000.

The Richman Brothers Company, Cleveland, plans an addition to its clothing factory to cost $700,000. The Miami Valley Co-operative Milk & Producers' Association, Dayton, Ohio, plans a new plant to cost about $100,000. The Miami Development Company, Dayton, Ohio, plans construction of a refrigerating plant to cost $150,000. Heller Brothers Company, Newark, N. J., plans a new plant at Newcomberstown, Ohio, to cost about $100,000. Randolph, Wis., will make extensions in municipal power plant to cost $58,000, including equipment. J. P. Larson, Lakota, N. D., is perfecting plans for a power plant at Clyde, N. D., for commercial service. Montpelier, N. D., will build a transmission line to connect with the system of the Otter Tail Power Company. The United States Power Company, Sioux Falls, S. D., is concluding negotiations for purchase of municipal property at Canistota, S. D. Elgin, Ill., and Seneca, Wis., plan ornamental street-lighting systems. Cedar Rapids, Iowa, is asking bids until April 23, and Shorewood (Milwaukee P. O.) Wis., will receive bids May 7, for ornamental lighting systems.

# Activities of the Trade

## Midland Lamp Division to Display Office Lighting

On May 1 the Midland Lamp Division of the National Lamp Works of the General Electric Company, A. H. Meyer general manager, will move from its present location at 625 South Wabash Avenue, Chicago, to larger quarters in the newly completed Adams-Franklin Building, 22 West Adams Street, Chicago. Friends and customers of the Midland Lamp Division have been invited to a formal opening reception, at which the model illumination prepared for the new offices will be turned on for the first time.

This illumination of the Midland offices and demonstration room will be an example of modern lighting. Different rooms in the suite of offices will be lighted with different designs of fixtures in order to portray a variety of ideas, and each room will present the finest modern practice for office illumination.

## American Metallurgical Reports Active Sales

Sales for the first quarter of 1928, as reported by the American Metallurgical Corporation, Boston, show an increasing trend toward the use of electric furnaces. Among recent deliveries are pot type furnaces to Pratt & Whitney Company, Hartford, Conn.; Ames Shovel & Tool Company, North Easton, Mass.; Union Hardware Company, Torrington, Conn.; Greenfield Tap & Die Company, Greenfield, Mass., and others. A number of box type furnaces ranging from 15-kw. to 70-kw. capacities were placed. In addition, the demand for special types is of interest with high-speed heating, special enameling and continuous types deserving attention. Repeat orders make up a good proportion of total sales.

## Consolidation of Sta-Warm and Price Pyrometer Effected

A consolidation of the Sta-Warm Company of Ravenna, Ohio, and the Price Pyrometer Company of Cleveland recently has been effected by H. C. Beckwith and will be known as the Beckwith Machine Company. Mr. Beckwith for ten years was active head of the Byers Machine Company of Ravenna. He resigned as general manager of the Byers company a little over a year ago, but recently was elected president and will continue in active association with Byers as well as with his other companies. Associated with Mr. Beckwith are J. Edwin Jensen, who will fulfill the duties of general manager, and H. E. Black, manager of the Cleveland branch office. Mr. Jensen was formerly general manager of the Sta-Warm Company, while Mr. Black was associated with the Price Electric Company.

The Beckwith Machine Company will continue the manufacture of Sta-Warm electric heating pots for glue, babbitt, wax, paraffin and similar products under the trade-name Sta-Warm. All of the manufacturing equipment of the Price Electric Company has been transferred to the Ravenna plant, where the production of resistance and thermo-electric pyrometers will be continued and marketed under the Price name.

THE STEINMETZ HEATING COMPANY, INC., 30 Church Street, New York City, announces that it is now marketing the "Wilnik" hot water bag heater and plain immersion heater. These units are automatic and will not operate unless immersed in water.

THE COPELAND SALES COMPANY, 630 Lycaste Avenue, Detroit, has started a series of sales schools to keep the field force in touch with the latest developments in its line of electric refrigerators. The first school was started by Vice-President W. D. McElhinny, with a meeting of the Michigan distributors, dealers and salesmen at the Strelinger-Copeland salesrooms, Detroit, on March 20. V. E. Vining, of the sales department, is assisting Mr. McElhinny in this work, which will completely cover the United States.

THE TRUMBULL-VANDERPOEL ELECTRIC MANUFACTURING COMPANY, Bantam, Conn., manufacturer of safety and knife switches, panelboards, etc., announces the opening of a new branch office at 10 High Street, Room 309, Rice Building, Boston, with Frank W. Garner as district sales manager.

THE BENJAMIN ELECTRIC MANUFACTURING COMPANY, 120 South Sangamon Street, Chicago, announces the appointment of G. B. Weber as manager of refrigerator sales. Mr. Weber, for several years assistant to the vice-president, has been in charge of sales of the commercial stamping and enameling division. R. W. Staud, advertising manager of the company, will direct advertising and sales promotion of the refrigerator division.

THE LINCOLN ELECTRIC COMPANY, Cleveland, manufacturer of "Linc-Weld" motors and "Stable-Arc" welders, announces the appointment of Jacob F. Savela as welding service manager for the Detroit district under the direction of J. M. Robinson, district sales manager.

THE H. C. ROBERTS ELECTRIC SUPPLY COMPANY, 514 Charlotte Street, Utica, N. Y., announces the removal to its new quarters in the recently finished building of the Westinghouse Electric & Manufacturing Company at 113 North Genesee Street. James Sidway, formerly manager of the company and of the Robertson-Cataract Electric Company in Utica, has been appointed vice-president and general manager of the Earner Electric Company at Cleveland, which, like the Utica firm, is another Westinghouse agent jobber. The shops of the Westinghouse company, now located at 19 Pine Street, will be removed to the new building about May 1.

THE HURLEY MACHINE COMPANY, 22d Street and 54th Avenue, Chicago, manufacturer of "Thor" washing machines, ironers, etc., announces the organization of the Thor Canadian Company, Ltd., for the manufacture and distribution of "Thor" products in Canada. The new plant is located in Toronto, Ont. F. H. Chapman is president, and J. F. Terry has been appointed vice-president in charge of sales.

THE WESTINGHOUSE ELECTRIC & MANUFACTURING COMPANY has received an order from the Shell Pipe Line Corporation, Shell Building, St. Louis, for electrical equipment for fourteen pumping stations in connection with a 700-mile pipe line running from McCamey, Texas, to Cushing, Okla. Each pumping station will have three 400-hp. motors and pumps and a four-panel switchboard.

THE STOW MANUFACTURING COMPANY, INC., Binghamton, N. Y., manufacturer of Stow flexible shafts and portable tools, announces that it is now offering the Stow direct connected suspended unit for industrial purposes.

DECELECO, INC., Wayne, Mich., manufacturer of precast slabs for switch cell construction in power plants and substations, has appointed the Van Rosen Company, Statler Building, Boston, as New England agent.

THE GENERAL ELECTRIC COMPANY has secured a contract for furnishing approximately $40,000 worth of motors to be installed in the "Kraft" paper mill now under construction in Tacoma, Wash., for the Union Bag & Paper Company. The motors, 250 in number, will range from 300 hp. to 2 hp.

THE W. N. MATTHEWS CORPORATION, St. Louis, manufacturer of electrical specialties and mechanical painting equipment, announces the opening of a new office in the Real Estate Exchange Building, Philadelphia, in charge of J. B. Harris. The territory will be Pennsylvania, east of Altoona, and the state of Delaware. The company also announces that A. L. Link will open an office at 40 West Seneca Street, Buffalo, N. Y. Mr. Link's territory will be that part of New York state west of, but not including, Albany. The E. S. Stickle Company, 934 Union Trust Building, Pittsburgh, will succeed M. P. McClure as the company's representative in the Pittsburgh territory covering Pennsylvania, west of Altoona, West Virginia and parts of Ohio.

# New Equipment Available

## Magnetic Switch

A magnetic switch, suitable for throwing squirrel-cage motors directly across the line, or for use as a primary switch for a wound-rotor motor, has been introduced by the General Electric Company. It bears the designation CR-7006-D-31. The switch consists of a triple-pole, restricted-blowout type, magnetically operated contactor with normally open interlock, and two hand-reset, temperature overload relays, all mounted on a molded base and inclosed in a drawn-shell, steel inclosing case. It is designed for use on standard voltages and frequencies, and the maximum horsepower rating at 220 volts is 50 for two or three-phase three wire and 60 for two-phase four-wire.

## Gas-Engine Driven Welder

A new model gas-engine-driven "Stable-Arc" welder, known as the S-1960 model has been placed on the market by the Lincoln Electric Company, Cleveland. The new unit has a rating of 200 amp. according to N.E.M.A. standards, with a current range for welding duty of from 50 amp. to 300 amp. and operates at a speed of 1,500 r.p.m. Motive power is provided by a four cylinder Continental "Red Seal" engine, type H-9.

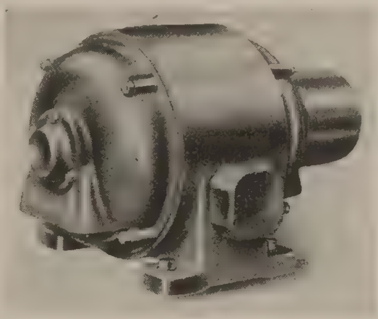
The welding generator and engine are mounted on a structural base welded into a solid piece of steel. This welded steel base provides a maximum stiffness and rigidity with a minimum weight; the whole unit weighing only 1,580 lb. and being only 76 in. long by 25 in. wide.

The generator also is constructed of steel, not only reducing the weight but also reducing the possibility of breakage in the field. The complete magnetic circuit of the generator is of laminated steel structure. A steel switchboard is provided. It is stated by the company that this unit is not designed to replace its present heavy duty engine driven equipment but to meet the need for a light but sturdy unit.

**Motor-Generator for Projection Work.**—A line of constant-potential, multiple-arc, induction motor-generator sets has been designed especially for motion-picture projection by the General Electric Company. These sets will operate on 50- or 60-cycle alternating current from the power lines. The line includes sets driven by single or polyphase, squirrel-cage, induction motors or by high-reactance, squirrel-cage, induction motors. All sets are given a continuous rating in kilowatts, ranging from 1.6 kw. on some types to 30 kw., and are designed to carry overloads of approximately 100 per cent for periods of three minutes occurring at fifteen-minute intervals. To secure stable operation of the arc, a ballast rheostat must be used in series with each projector, spotlight, etc. This will reduce the voltage from that furnished by the generator to that required by the lamp. A line of generator panels for wall mounting, suitable for use with these sets, is also announced by the General Electric Company.

## General Purpose Motor

A line of ball-bearing general purpose motors in sizes from ¼ hp. to 30 hp. has been developed by Sterling Electric Motors, Inc., Los Angeles, Cal. The motor is interchangeable for 220 or 440 volts and is of the across-the-line type.



*Protected general purpose motor for 220 or 440-volt use*

It is a semi-inclosed unit and can be furnished for single-phase operation with condensers for starting and improving the power factor. This protected motor can also be used as a totally inclosed unit, totally inclosed pipe ventilated or totally inclosed ventilated. The cast rotor used is guaranteed for the life of the motor, and the stator frame is of one piece construction.

## Open Type Fused Switch

An open type "Fuswitch" which has been designed for rural and farm lighting and railroad use to meet the demand for a low-priced switch of high rupturing capacity has been placed on the market by the W. N. Matthews Corporation, St. Louis. The switch is known as the No. 1317, and has a rating of 100 amp. at 7,500 volts. It is of the vertical type and is especially designed for 6,600-volt and 6,900-volt service but is adaptable to 2,300-volt and 4,400-volt service.

The switch is equipped with the Matthews double tube horn fiber vacuum cartridge. The insulators are of special design wet process porcelain with a flashover value of 22 kv. The switch can be quickly converted to a disconnecting switch with a rating of 125 amp. at 7,500 volts by substituting the solid disconnect blade made for the purpose.

## Single-Phase Condenser Type Motor

A complete line of condenser-type single-phase motors in all speeds and sizes up to 30 hp. has been placed on the market by the Howell Electric Motors Company, Howell, Mich. These motors are built in a range of speeds from 3,600 r.p.m. to 300 r.p.m., and are said to be particularly adapted to slow speeds owing to the high power factor. In most sizes the line is mechanically interchangeable with Howell polyphase motors. They are built with standard sleeve bearings or Timken tapered roller bearings and are obtainable in horizontal, vertical, open, totally inclosed, or inclosed ventilated types. The motor is suitable for plugging or for use on reverse speed duty with the use of a three-phase reversing switch.

The condenser used with the motor is contained in an auxiliary box for connection external to the motor. The type of condenser furnished is dependent on the starting torque requirements. The manufacturer claims that the starting torque of the motor can be made as great or greater than that of a polyphase motor. The power factor of the motors range from 80 per cent to 100 per cent and the efficiency from 70 per cent to 90 per cent.

## Disconnect Switch and Fuse Mounting

A combination disconnecting switch and fuse mounting known as the type "GFB-232" for underhung mounting on double cross arms has been placed on the market by the Delta-Star Electric Company, Chicago. This unit is particularly applicable for use on two pole platform type substations placed directly under the transmission line. Fuses are easily removed and disconnecting switches readily opened by an operator standing on the platform. Where there is possibility of a back feed a disconnecting switch may be furnished on both sides of the fuse to provide maximum safety.

**Pot-Type Electric Furnaces for Lead Hardening.**—An addition to its line of electric heating equipment in the form of a pot-type electric furnace for lead hardening, designed to operate at temperatures up to 1,650 deg. F. has been made by the General Electric Company. It is being marketed in four sizes. This furnace, the manufacturer claims, consumes less current than any other pot-type furnaces of similar size and capable of doing the same work. It utilizes the standard method of submersing the work in a bath of molten lead. The four sizes now in manufacture cover a wide range of production conditions and are suited to a multiplicity of applications. The smallest has a maximum capacity of 75 lb. of steel per hour at 1,500 deg. F. The largest unit has a capacity of 250 lb. of steel per hour at 1,500 deg. F.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued March 20, 1928)

1,663,334. Support; H. P. Chandler, Mansfield, Ohio. App. filed July 27, 1926. Support for suspending and insulating a trolley conductor.

1,663,343. Renewable Fuse; M. M. Lear, Jamestown, N. Y. App. filed March 17, 1926.

1,663,357. Lighting Fixture; G. Stefan, Chicago, Ill. App. filed Feb. 2, 1927.

1,663,421. Line Breaker; E. L. Stubbings, Huntington, N. Y. App. filed March 10, 1927. For breaking the loops in street lighting circuits.

1,663,466. Neutralizing Bar; A. J. Rostal, Chicago, Ill. App. filed Aug. 28, 1924. For application to a printing press or other machine through which paper is passed for removing static electricity from the paper.

(Issued March 27, 1928)

Reissue 16,917. Exit-Lighting System; R. T. Williams, Chicago, Ill. App. filed Dec. 3, 1926.

1,663,550. Lamp Stem Holder; J. J. Higgins, East Orange, N. J. App. filed Dec. 3, 1924.

1,663,551. Alternating-Current Relay; E. L. Holmes, New York, N. Y. App. filed Jan. 24, 1925.

1,663,552. Electrolytic Rheostat; E. L. Holmes, New York, N. Y. App. filed Jan. 24, 1925.

1,663,558. Electric Heater; N. Lawner, Brooklyn, N. Y. App. filed May 20, 1927. To be used as a vaporizer for the treatment of certain diseases, such as asthma.

1,663,560. Filament for Incandescent Lamps; G. W. Meister, Irvington, N. J. App. filed Feb. 20, 1926.

1,663,564. Refractory Metal Filament; M. N. Rich, East Orange, N. J. App. filed Oct. 30, 1925.

1,663,607. Electric Power Transmitter; J. M. Naul, Plainfield, N. J. App. filed Nov. 21, 1924. Used in the individual drive and control of small machines such as sewing machines.

1,663,654. Lighting Fixture; E. F. Guth, St. Louis, Mo. App. filed July 13, 1925.

1,663,655. Supporting Means for Lighting Fixtures; O. D. Guth, St. Louis, Mo. App. filed July 15, 1925.

1,663,657. Lighting Fixture; E. F. Guth, St. Louis, Mo. App. filed Feb. 17, 1926.

1,663,674. Limiting Device for Electric Regulators; A. Ytterberg, Furuhall, Ludvika, Sweden. App. filed April 6, 1926.

1,663,675. Electric Cigar Lighter; J. R. Ayotte, Chicago, Ill. App. filed April 24, 1926.

1,663,680. Electric Switch; N. G. Copley, Detroit, Mich. App. filed June 27, 1925. Small automatic overload switch.

1,663,698. Spacing and Supporting Bridge for Storage-Battery Plates; W. E. Gossling, Indianapolis, Ind. App. filed Sept. 5, 1923.

1,663,711. Electrical Apparatus; J. M. Laler, Burlingame, Calif. App. filed March 23, 1925. Terminal boxes and connecting plugs.

1,663,741. Secondary Battery; J. Vaughan-Sherrin, Ruckinge, England. App. filed Aug. 4, 1926.

1,663,768. Electrical Measuring Instrument; J. H. Miller, Oak Park, Ill. App. filed March 25, 1922. With means extending externally of the instrument housing through which the conductor may be passed, and which will act to produce the necessary torque on the vane of the indicating needle of the instrument.

1,663,807. Chart-Recording Meter; F. Maurer, Zug, Canton of Zug, Switzerland. App. filed June 16, 1922.

1,663,810. Electric Heater; S. Morse, Cleveland Heights, Ohio. App. filed Feb. 6, 1926.

1,663,874. Heating System; W. W. Brisson, Norway, Mich. App. filed April 7, 1927. For railway switches.

1,663,878. Multiple-Conductor High-Tension Cable; L. Emanueli, Milan, Italy. App. filed Sept. 2, 1925.

1,663,885. Electromagnetic Device; N. H. Holland, West Orange, N. J. App. filed Aug. 14, 1924. As used in sound recording and reproducing apparatus.

1,663,890. Electrical Control System; H. M. Stoller, Mountain Lakes, N. J. App. filed Nov. 19, 1924. For controlling the speed of dynamo-electric machines.

1,663,891. Regulator System Employing-Electron Discharge Devices; H. M. Stoller, Mountain Lakes, N. J. App. filed July 24, 1926.

1,663,970. Means for the Electric Welding of Can Bodies; J. Brenzinger, Fairfield, Conn. App. filed July 1, 1925.

1,664,022. Electric Welding Apparatus; A. Churchward, New York, N. Y. App. filed Feb. 17, 1927. Auxiliary regulating means.

1,664,030. Method of and Apparatus for Electric-Resistance Welding; J. H. Gravell, Elkins Park, Pa. App. filed March 23, 1926.

1,664,031. Electric Jet-Wave Commutator and Interrupter; J. F. G. P. Hartmann, Copenhagen, Denmark. App. filed Feb. 25, 1926.

1,664,089. Thermostatic Control for Generators; C. Ringwald, Chicago, Ill. App. filed Feb. 23, 1926.

1,664,090. Attachment-Plug Adapter; H. R. Sargent, Bridgeport, Conn. App. filed Feb. 27, 1923.

1,664,097. Protective Device; O. C. Traver, Schenectady, N. Y. App. filed Feb. 1, 1924. For the protection of high voltage electric circuits upon the occurrence of abnormal conditions, such as excess current.

1,664,100. High-Tension Installation; A. O. Austin, Barberton, Ohio. App. filed Oct. 20, 1921. The combination with a conductor, of an openwork conducting cage surrounding the conductor and spaced outwardly for increasing the effective diameter of the conductor.

1,664,104. Electromagnetic Device; E. R. Carichoff, Schenectady, N. Y. App. filed Feb. 9, 1924. Magnetic switch.

1,664,107. Electric Bell; W. F. Hendry, Ossining, N. Y. App. filed Sept. 12, 1924.

1,664,126. Dry-Battery Construction; E. E. Meisekothen, Madison, Wis. App. filed Aug. 28, 1925.

1,664,132. Electric Furnace; I. Rennerfelt, Djursholm, Sweden. App. filed Aug. 18, 1926. Metallic resistor type.

1,664,134. Speed-Control System; L. Schombourger and H. K. Schrage, Paris, France. App. filed May 6, 1925. For an induction motor.

1,664,165. Dimmer Wall Switch; G. Freeman, New York, N. Y. App. filed April 1, 1927.

1,664,171. Electrical Baseboard Heater; W. W. Hicks, San Francisco, Calif. App. filed Dec. 17, 1925.

1,664,172. Insulator; J. R. Holler, Ellwood City, Pa. App. filed July 20, 1926. For supporting electric cables in mines, or elsewhere.

1,664,173. Electric-Welding-Machine Attachment; C. W. Holstein, Warren, Ohio. App. filed July 11, 1927. For spot welding machines of the pivoted conductor-carrier type.

1,664,177. Electric Heater; A. J. Kercher, Berkeley, and W. W. Hicks, San Francisco, Calif. App. filed Aug. 26, 1926.

1,664,185. Braking System for Motor-Driven Machinery; T. H. Rodman, New York, N. Y. App. filed Oct. 25, 1922. Applicable to high-speed printing presses.

1,664,194. Protective Device; E. E. F. Creighton, Schenectady, N. Y. App. filed Sept. 5, 1924. Whereby abnormal potential charges, such as atmospheric disturbances, static accumulations, etc., may be carried off without injury to the apparatus.

1,664,201. Thermostatic Switch; C. J. Fay, Mansfield, Ohio. App. filed March 10, 1927.

1,664,208. Insulator; G. I. Gilchrest, Derry, Pa. App. filed Sept. 16, 1922. Suspension insulator adapted for high-potential circuits.

1,664,215. Annunciator Relay; L. F. Hunt, Los Angeles, Calif. App. filed April 21, 1923.

1,664,216. Motor-Control System; H. D. James, Edgewood Park, Pa. App. filed Sept. 2, 1922. For preventing the opening of circuit-controlling devices while excessively heavy current is traversing the circuit.

1,664,228. Switchboard Lamp; H. P. Sparkes, Pittsburgh, Pa. App. filed May 7, 1923.

1,664,229. Drier-Control System; S. A. Staege, Pittsburgh, Pa. App. filed July 23, 1925.

1,664,234. Coil-Ironing Machine; J. R. Weaver, North Irwin, Pa. App. filed July 14, 1923. Adapted to iron the insulating coils formed about electrical conductors such as coil members comprising windings of dynamo-electric machines.

1,664,242. Gas-Electric Power System; A. H. Candee, Wilkinsburg, Pa. App. filed Feb. 19, 1927.

1,664,243. Maximum-Demand Meter; L. W. Chubb, Edgewood Park, Pa. App. filed Dec. 11, 1922.

1,664,250. Variable Resistance Indicator; T. M. Eynon, Philadelphia, Pa. App. filed Aug. 10, 1922.

1,664,265. Liquid Gage; F. Rieber, Berkeley, Calif. App. filed July 28, 1924.

1,664,325. Motor Regulator; P. F. Shivers, Wabash, Ind. App. filed March 21, 1924.

1,664,326. Relay Operation Indicator; H. P. Sleeper, East Pittsburgh, Pa. App. filed March 10, 1923.

1,664,358. Lighting and Battery-Charging System; J. T. Fitzsimmons, Dayton, Ohio. App. filed Nov. 29, 1924.

1,664,380. Snap Switch; S. A. Meyers, San Francisco, Calif. App. filed July 15, 1926

# New Trade Literature

ANCHORS.—The W. N. Matthews Corporation, 3722 Forest Park Boulevard, St. Louis, has issued a price sheet covering its "Xpandix" anchors. This supersedes price sheets P and Q.

ELECTRICAL MATERIALS. — Catalog No. 25-1400 issued by the Truscon Steel Company, Youngstown, Ohio, covers the Truscon electrical materials for line construction. It contains a complete list of pole line hardware and specialties and the various products listed are all illustrated and described. An alphabetical and numerical index section at the end of the catalog gives instant reference to any article.

ELECTRIC SPECIALTIES.—The G & W Electric Specialty Company, 7780 Dante Avenue, Chicago, has issued catalog No. 27, in which it fully illustrates and describes the G & W electric specialties, including potheads, boxes, combination air and oil break, disconnects, vault units, cable terminal devices, distribution specialties, etc.

TRANSMISSION BELTING.—A booklet issued by Alexander Brothers, Inc., 14 South Street, Philadelphia, describes in detail the construction of "Tentacular" transmission belting. It contains typical installations and complete information, including horsepower ratings, etc. A chapter is devoted to the design of a "Tentacular" drive and an example illustrates the application of the principles.

LIGHTNING ARRESTERS.—"The Economics of Lightning Protection" is the title of booklet No. 250, the sixth of a series describing the technical features of the crystal valve lightning arrester as they apply to modern lightning protection and which is being issued by the Electric Service Supplies Company, Seventeenth and Cambria Streets, Philadelphia.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

Purchase is desired in Milan, Italy (No. 30,547), of rubber-covered spark cable.

Purchase and agency are desired in Naples, Italy (No. 30,597), for personal electrical equipment and electric stoves and water heaters.

Purchase or agency is desired in Munich, Germany (No. 30,555), for household electrical appliances and bare and insulated copper wire.

An agency is desired in Quebec, Canada (No. 30,556), for household electric washing machines, ironers, and clothes-drying cabinets.

A sole agency is desired in San Juan, P. R. (No. 30,579), for domestic lighting fixtures.

Purchase and agency are desired in Bilbao, Spain (No. 30,558), for electric refrigeration units.

Aktb. Sundell and Company, Sodra Kungstornet, Stockholm, desires an agency (No. EE-1071) for 2-volt storage batteries in glass jars.

## *What Is the Significance of the Portland Election?*

WHEN at a special election last week the people of Portland, Ore., refused by a two-to-one vote to sanction the sale of the Northwestern Electric Company to its competitor, the Portland Electric Power Company, they indicated a preference to maintain competition in the public utility field rather than accept a guaranteed 10 per cent rate reduction for a period of five years. The proposed consolidation would have meant an aggregate saving to Portland consumers of approximately $3,000,000 during the next ten years. Under the present franchise of the Northwestern company, which has ten years to run, the city of Portland receives a 3 per cent gross earnings tax.

There was little outward opposition to the consolidation, which by virtue of a requirement in the franchise of the Northwestern company had to be sanctioned by the City Council. The Council had expressed its approval of the merger, but officials of the two companies, desiring to have a full expression of public opinion, defrayed the expense of a special election at which no other issue was involved. The returns would seem to indicate that either the people lacked confidence in the companies and the set-up proposed or felt that competition in the public utility field is the surest safeguard to low rates. It was to check the arrogance of the old Portland Railway & Light Company under the late Mr. Josselyn that the city invited the Fleishhackers to start the Northwestern company. This and the fact that telephone rates in Portland were increased following the absorption of a small independent telephone company by the larger company may have had a bearing on the result. The fact remains, however, that 50 per cent of the registered voters of Portland refused to indorse the proposition. That is significant enough to cause the industry in that section to indulge in some introspection.

## *National Authority Must Not Trespass on Domain of Business*

PRESIDENT COOLIDGE voiced the above sentiment in an address last Monday night to the Daughters of the American Revolution. He was even more firm in his conviction that the policy of keeping the government out of business was one of the essential declarations of the Revolutionary period. The President has expressed himself in a similar strain on many other occasions, but such is the temper of Congress that the principle cannot be reiterated too often.

"Society requires certain public activities like highways and drainage, which are used in common and can best be provided by the government," he asserted; "but in general the country is best served through competition of private enterprise. If the people are to remain politically free, they must be economically free. Their only hope in that direction is for them to keep their own business in their own hands."

Before Congress at the present time are two major measures of interest to the nation and of chief import to the electric light and power industry—those concerning Muscle Shoals and Boulder Canyon. In both of these cases the government, or rather a minority in Congress, seeks an innovation which is at variance with the established practices of the nation. Not only would these men plunge the government into business; but in the Boulder Canyon measure, for example, they seek to coerce the states. Before the six or seven states involved in this legislation have even ratified a treaty, Congress, whose function in this case should be to confirm the agreement, seeks to initiate a movement which cannot become effective until the states and the Congress itself sign the treaty. All this is contrary to the policy of the administration and to the best traditions of the United States.

The electrical industry should press for a decision on the pending legislation now being debated in Congress in keeping with the principles enunciated by the President. Senator Norris ought not to be able to thwart the will of the people and of the Congress indefinitely, nor should Senator Johnson of California succeed in hoodwinking the nation into pouring millions into that already doubly blessed state at the expense of its neighbors. The rights fought for by the founders and the ideals they set up have proved their worth. To maintain them unshaken is both an ideal and a duty.

* * * *

## *British Electrical Performance and Its Handicaps*

A COMPARISON of the performance of the electric light and power industry of Great Britain with that of the United States is interesting. While the showing is highly complimentary to the utility companies of this country, it is not altogether bad for Great Britain if all the facts are taken into consideration. It does indicate, however, that there is opportunity for great improvement and that the Electricity Commissioners, if adequate powers are granted them, can work wonders in a country possessing abundant fuel, manifold industries and congested population.

The annual analyses and summaries of electricity output in Great Britain for the year ended March 31, 1927, have just been published by the Electricity Commissioners. They show a total output of 8,365,857,198 kilowatt-hours, an increase of less than 3 per cent, from a fuel consumption of 8,856,938 tons, an increase of 4.8 per cent over 1926. The average fuel consumption increased from 2.40 pounds to 2.43 pounds per kilowatt-hour, the best showing having been made by the Barton station of the Manchester Corporation, which on a load factor of 53.2 per cent generated a kilowatt-hour from 1.33 pounds of coal. Of course, heat units rather than pounds of coal would have been a better yardstick; but pounds of coal will suffice. Moreover, the Barton station, because of inadequate condensing water, depends on cooling towers, like many other stations in Great Britain, and therefore is at a disadvantage compared with American stations possessing ample condensing water.

The total production of electricity from public utility stations in the United States in 1927 was approximately 80,000,000,000 kilowatt-hours. In kilowatt-hours the electricity produced by the use of fuel increased about 5½ per cent, and notwithstanding that 2,500,000,000 more kilowatt-hours of electricity was generated from fuel in 1927 than in 1926, the fuel consumption decreased about 150,000 tons. The average of all steam stations was 1.83 pounds per kilowatt-hour, compared with 1.95 pounds in 1926, and our best stations consumed less than a pound of coal per kilowatt-hour. This is a wonderful record compared with that of Great Britain and indicates that private initiative is more alert and responsive in the United States than in Great Britain, where the municipalities make the better showing. There are, of course, reasons for this; but even at best Great Britain's municipal showing is only about half as good as our best privately owned system. We produced approximately 50,000,000,000 kilowatt-hours from fuel last year and consumed 45,709,000 net tons of fuel. When Great Britain's superpower system becomes effective, our cousins will be able to do better; but, owing to municipal opposition, economic reforms are hard to effect on that conservative island so important in the world's industry.

## *The Salesman's Approach to the Executive*

FOR a long while the sales managers of the power industry have complained of the lack of executive interest and support in their work. The executive, they say, is so absorbed in operating, engineering and finance that he will not give much thought to selling. This has been true, and because of the nature of the business in past years it is not hard to understand, for the market has always grown on insistently. But has it occurred to the commercial men that a little study of their own methods will disclose one reason why it has been so difficult to get the president or the general manager really interested in sales methods? The salesmen have not been accustomed to presenting their plans and purposes in the form that appeals to the executive.

After all, this is a business enterprise, the operation of a power company. Behind the executive stand the banker and the stockholder. When the president goes before his board of directors with a project to build a new station he must bring a full story—the necessity for it, the plan, the cost involved, the benefits to be expected, and what is involved in financing, in engineering, in operating and in organization. It is a complete picture. And that is what the president likes to see when a subordinate submits a proposition. Moreover, he is accustomed to this approach to a decision on engineering programs. Is it any wonder, therefore, that he has at times failed to react to sales plans that are reared on a substructure of enthusiasm and opportunity?

The central-station commercial man has been too inclined to feel that if he sets up a sales program and volunteers to put it over, he is doing his share of the job and can leave all questions of the capital required and how to raise the money to the chief executive, disregarding the fact that any large development of market also entails the extension of lines, the substitution of heavier transformers and feeders and often the purchase of additional station equipment. Such an attitude naturally discredits the sales department. It suggests a lack of broad judgment and responsibility. But if a proposal for a market-building project was submitted as a complete business proposition, embracing all considerations of finance, engineering, operating and sales organization and promotion, it would have a very definite reception. The executive could weigh it in its entirety. He would not have to reconcile it to other department plans, for all that would have been done in advance. It would bring new dignity to the sales department in the mind of the executive.

## *Cables in Surface Trenches*

DIFFERENCES between American and European practice in the installation of high-voltage cables underground have always presented an interesting question for analysis and speculation. In this country it is the almost universal practice to draw such cables into rigid underground conduits or ducts, usually placed a greater or less distance below the surface, access to the ducts being had through manholes spaced at intervals determined by the cable lengths and the mechanical stresses necessary to pull them in. Abroad it is common practice to place the cables in trenches open from the surface, the necessity thereby arising for armoring the cables against mechanical injury and for protecting the covering against various difficulties arising in the contact with the soil. The highly developed duct bank of this country obviously offers greater economy of valuable space beneath city streets. Further, there is the greater facility for inspection and for removal of defective cable sections. For these and other advantages payment must be made in the increased costs of material and construction.

An advantage of the European practice that is sometimes lost sight of is the smaller degree of handling to which the cable is subjected, particularly in the matter of bending, resulting from the simple process of unreeling into an open surface trench. This undoubtedly imposes less mechanical strain on the insulation, less probability of the breaking of paper tapes and of the formation of gas voids between insulation and sheath. With this danger lessened it is possible to wrap a tighter cable, with resulting improvement in its insulating properties. It is therefore of interest to note that at the recent meeting of the underground systems committee of the National Electric Light Association in Louisville the subcommittee on conduit and manhole construction reported two instances of the laying of cables in open trenches. In one of these cases a special concrete cable way was made, and in the other the cable was laid directly into soft earth. In each case protection from above was afforded by concrete slabs. The essential features, however, were the simplicity of the process of installation, resulting from the straight travel of the reel over the open trench, and the economy in the matter of cost. In view of the tendency to higher voltages for underground cables and the limitations which are imposed by present methods of manufacture and knowledge as to the ultimate properties of impregnated paper, it seems not improbable that a substantial increase in voltage limits and reliability of service might be looked for by taking advantage of the increased freedom in design permitted for cables which are to be installed in open trenches.

## *An Industrial Plant's Tribute to the Electrical Industry*

THE manner and the extent to which electrical energy and electrical equipment are used in the fabrication of a finished product and their effect upon its quality may be accepted as the true measure of the value of the electrical industry's service to an industrial plant. A case in point is the electrification of the Timken Roller Bearing Company's plant at Canton, Ohio, where all power is purchased from the Ohio Power Company. This plant now has a maximum demand of 30,000 kilowatts, which is steadily increasing. The fact that, with such a large demand for power, the plant finds it most economical to purchase its requirements is proof positive of the superiority of central-station service under the conditions presented.

If any further proof of the value of electrical apparatus were needed, the methods of utilization and their effect upon the finished product would supply it. At this plant there is in operation a battery of electric steel-melting furnaces producing 350 tons of steel a day. All of this electric steel, and this steel only, is used in the manufacture of the company's products, although it is also operating an open-hearth furnace for the production of merchant steel. So highly does this industrial plant value the quality of electric steel that it will soon double its capacity in steel-melting furnaces. In addition to this, more than 3,000 kilowatts in electric heat-treating equipment has been installed within the past year to take further advantage of the refinements in production which electric service and electrical equipment afford. The quality of its product, its uniformity and its wide field of application in other industries are attributed by the Timken company largely to the utilization of electrical energy and electrical equipment in its own fabricating processes. Surely the electrical industry can ask for no higher tribute to the value of its own service and its own products.

* * * *

## *The Urban Trend in Management*

GOOD relations with customers are leading to a rapid decentralization in local utility management under the holding-company principle. The rewards of putting a responsible resident manager in each important regional area are very attractive, and the policy will be continued for some time in progressive organizations. When one comes to the larger tasks of company administration, however, it is apparent that centralization of executive and technical allied and advisory functions is steadily increasing. The trend is away from the smaller town or city to the larger one or to the more conveniently located community with regard to banking connections, concentration of engineering and sales ability, access to specialist service and general business facilities.

The time is at hand when a large part of the development work of major property groups will be carried on under conditions more favorable to highly organized treatment than ordinarily obtains in the more isolated centers. Policies will be determined on the basis of local experience no less than before, but a better co-ordination will be realized in engineering, purchasing, general direction of sales activities, accounting and financing work, if strong ties between headquarters and district offices are maintained and the resources of the larger or more favorably manned centers are utilized with sound judgment and never-failing perspective. It would be ridiculous to imply that a first-class administration of a modern group of utilities cannot be conducted from a country-town office, and no such intimation is intended; but the massing of business facilities characteristic in urban centers and the increasing complexity of operating, engineering and development problems, the need of the most experienced legal advice and of the most competent financial opinion and support lie behind the present trend toward the larger city as the base of executive operations. The best resources of modern business must be made as convenient as possible to the administration of the immense aggregations of capital now invested in the light and power industry.

## *Profitable Rural Service*

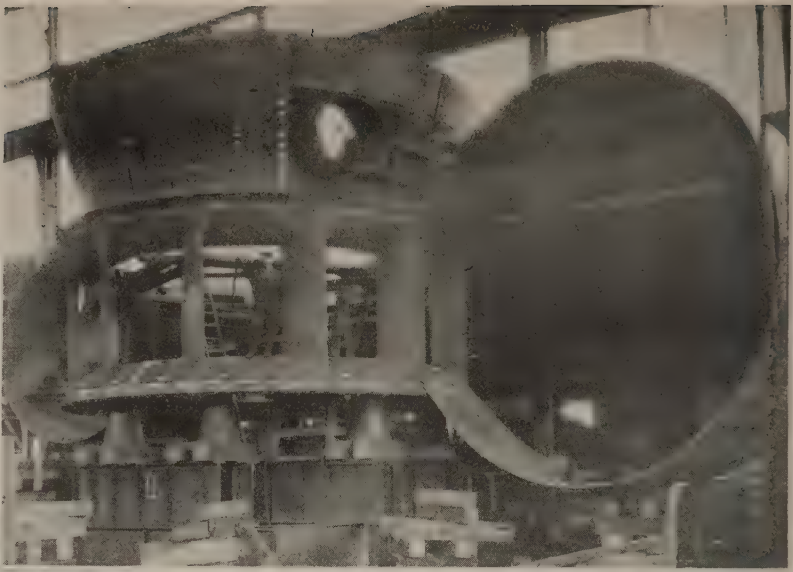
RURAL service lines, with few exceptions, are at first unprofitable. It is not unusual for such an extension to continue as a losing venture for many months, even years, after it is energized. Many suggestions have been offered to improve this condition, but the fundamental consideration cannot be avoided. A profitable line depends entirely upon the utilization of the electrical service provided by that line.

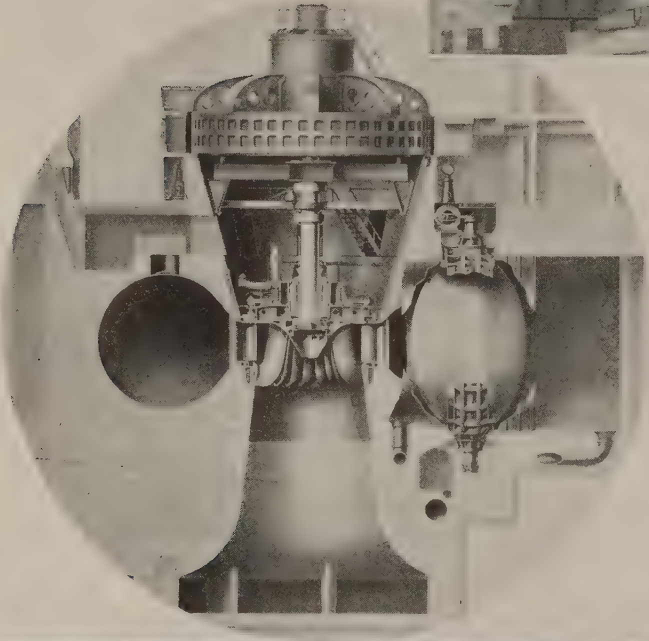
A number of operating companies in one large system have been able to shorten the period of unprofitable service through intensive efforts to have each property owner along the route "signed up" as a customer before the construction work is undertaken. The policy on this system is to start work only when 80 per cent of the potential customers have signed contracts for service. Experience has shown that such agreements can be obtained as a result of adequate effort.

There is an excellent way in which existing lines and those planned for future installation may comprise improved revenue factors. Highway-lighting practices in rural districts are consistently inadequate. A lighting load of sixteen or eighteen 600-cp. lamps per mile offers sufficient illumination to increase safety conditions along the roadway and at the same time augment the load on the extension. It is estimated that such a minimum specification represents an average annual cost of $700, and, as the highway construction requires a probable $35,000 per mile, the expenditure for illumination amounts to a potential expense increase of 2 per cent per year. A Middle Western utility supplies such a service for $48 per mile per month along 343 miles of rural roads.

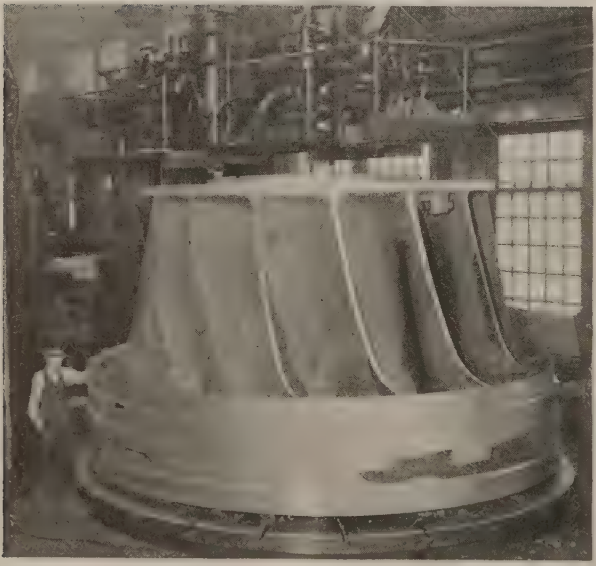
There is a certain obligation upon a community to assist in the illumination of highways just as there is a definite obligation upon it to provide the highway. Adequate lighting will place a portion of the burden of the cost of line extensions upon the members as a whole. After all, it is, definitely, a community matter, this provision of safe highways and better homes.

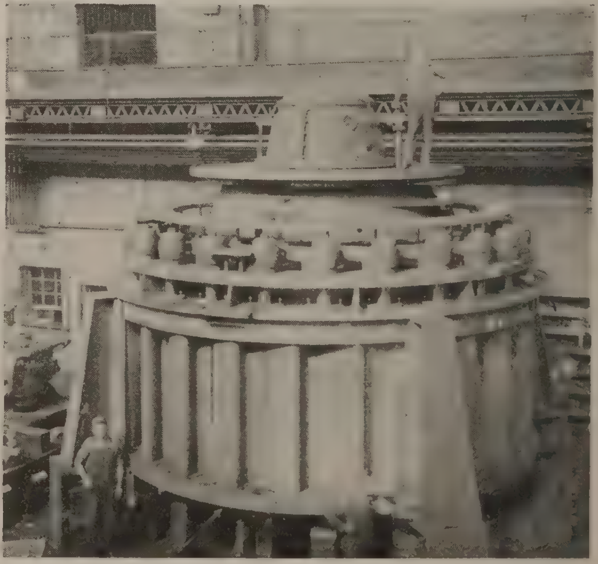
# *Conowingo Units Now on Line*





ON MARCH 1 the Conowingo hydro-electric development of the Philadelphia Electric Company commenced feeding Philadelphia. It is tied in with the Pennsylvania Power & Light Company and will be eventually with the Public Service Electric & Gas Company of New Jersey. The plant, with its initial equipment of seven 54,000-hp. turbines designed for 89-ft. head, was completed and placed in operation in virtually two years. The total cost will be around $52,000,000. The types of runner, spiral casing and speed ring used in four of the units are illustrated.





# *Relation Between*
# Steam and Hydro Generation

Too much emphasis placed on competition.
Both types of power generation have field.
Opportunities exist for lowering hydro costs

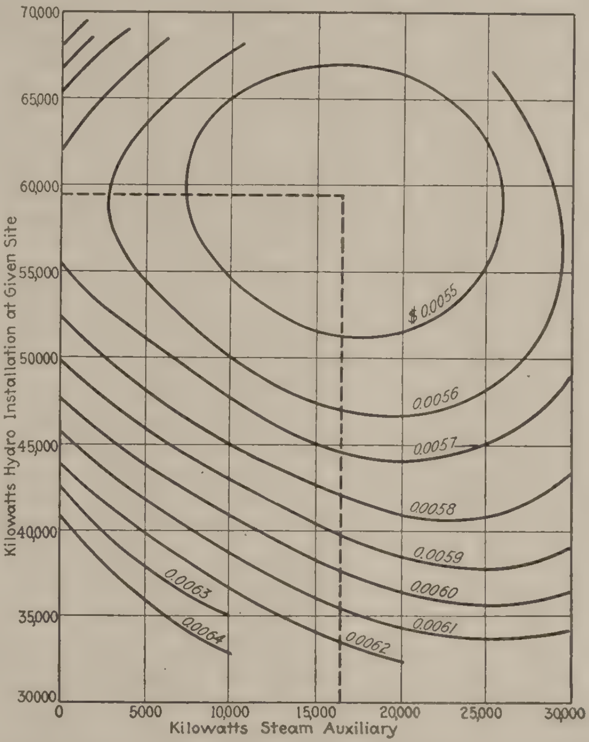
By C. P. Dunn
*Chief Engineer Portland Electric Power Company, Portland, Ore.*

DISCUSSIONS of problems concerning the relative economy of steam-electric and hydro-electric power generation have appeared in the technical press during the past year or two. In the opinion of the writer, the idea of steam versus hydro has been presented with too much emphasis on the thought of direct competition between the two methods of generating power. It is true that to a certain extent a direct comparison may be made, but, in general, the two methods of obtaining electric energy are inter-related in so many ways, and each makes such an admirable supplement to the other with respect to suitability for carrying different types of load, or different parts of the annual or daily system load, that in districts where both types of generation are available we must regard them as inseparable. They will remain so until a better way is invented of obtaining electric energy than from a properly balanced group of steam and hydro stations.

In districts where both sources of generation are available at reasonable cost the two working together will usually produce power more economically than either alone. The exceptions are: (a) Districts where hydro possibilities are so meager as to allow of little or no development in competition with modern steam plants, and (b) districts so favored with economical hydro sites (including storage) as to preclude the economical operation of steam plants, even for carrying peaks. This latter condition is extremely rare because of the scarcity of good storage sites. Lack of economical storage reservoir sites usually makes it necessary to have steam auxiliaries for carrying load in the low-water season.

Recent developments in automatic control have made it economical to use kilowatt-hours from small hydro sites which were formerly out of reach because of operating cost.

It is true that even in the western part of the United States, where enormous supplies of hydro energy lie undeveloped, the ratio of steam to hydro is rapidly increasing. This is the natural result of changing economic conditions. The rapid changes in methods of doing things which are taking place in all lines of human activity make it necessary to look forward, and to be flexible. The cost of new hydro has been increasing of late years because the best sites have been developed, the remaining sites of ordinary size require a greater investment per kilowatt and the rate of growth of demand for power does not yet justify the construction of the large hydro developments which can be built at a low unit cost, and which would be economical if they could be loaded quickly. The cost of steam power has been coming down because of increased efficiency due to the recent great advances in the art of generating power by steam.



*Typical analysis of economic relation between size of hydro installation and steam auxiliary*

Cost per kilowatt-hour of maximum usable power delivered by various combinations is shown by the "cost contours." For the given conditions covered by the chart the most economical development would be 59,000 kw. hydro and 16,500 kw. steam as shown by the dotted lines.

Some of the very large hydro-electric sites in the West appear to offer very cheap power, but when consideration is given to the fact that this apparently cheap power is located so far from the consumer that 220 kv. transmission is necessary, and construction of both generating stations and transmission lines are of a nature to require capital outlay for large steps in capacity, putting at the disposal of the consumer more power than he can use for a period of several years, but nevertheless burdening him with the cost of having this capacity available, the picture of cheap power from falling water disappears and thought is given to steam. Steam can be installed in steps or units as small as may be desired, but the greatest thermal efficiency is not available to systems which cannot readily absorb the output of a unit of 30,000 kw. capacity or more.

The two methods of obtaining power are, in general, about on a par as to reliability. Steam-generating units alone are less reliable than hydro-generating units, but when the chances for trouble in hydro plants other than in the unit itself, such as trouble on transmission lines, trouble with ice, conduits, valves, or gates, are charged against the hydro installation they are about equal. In the case of the steam plant, there is seldom an outage due to any cause except the unit itself, because of the custom of providing spare boiler and fuel-handling equipment.

### Field for Both Steam and Hydro

In comparing steam with hydro, or one hydro plant with another, there is too often a tendency among those not fully informed to give attention only to the particular development under consideration, with not enough study of the effect the development will have on the system to which it will be connected. The economic design of any individual development, if correctly worked out, must be influenced by the characteristics of all existing plants and other potential developments within reasonable transmission distance. There is no way really to measure the usefulness of a proposed development except to make detailed calculations of system operation, not plant operation. In a new development the thing to be accomplished is to build not just a plant which will produce power but a plant which will produce a certain amount of power at certain times, and to fit the new plant as nearly as possible to the work it has to do. Power spoken of as "kilowatt-hours," with no qualifying terms, has no clearly defined value. The value of a kilowatt-hour is determined not by the fact that it is a definite amount of energy, but by the ability or inability of the seller to deliver it, on demand, at any hour of the day or night or at any season of the year. Electric service consists of carrying both peaks and kilowatt-hours; the mention of either without a very specific definition of the relation between the two results in an incomplete description of the service in mind.

The cost of installation is, in the case of steam plants, from $80 to $120 per kilowatt, and in the case of hydro from $150 to $300 per kilowatt. This, with the fact that steam-operating costs and rates of depreciation are much greater than hydro, tends to make the steam plant more desirable for peak generation and the hydro plant more desirable for carrying the base of the daily load curve.

As for the contest between steam and hydro, if it may be said that a contest exists, there is usually a place for a good steam plant on the daily peak in a district where hydro is economically predominant, and there will always be a welcome extended to the intermittent hydro kilowatt-hours, which help reduce the coal bill in a district where steam is predominant. Economic laws will dictate the proper procedure in any given district.

The determination of the proper size of steam installation to suit a given set of conditions as to fixed charges, operating costs, stream flow characteristics and load characteristics is a very complicated problem. The fact that it is complicated makes it desirable to avoid decisions based on incomplete study. The only way to get a true picture of all the factors bearing on the problem, in their proper sequence and magnitude, is to analyze loads, costs and system and plant performance graphically. The accompanying chart is submitted as an illustration of graphical analysis of a problem of this nature. The detail calculations and numerous other graphs which make up the supporting data are necessarily omitted from this article.

### Efficiency and Construction Costs

We read in the current discussions of steam versus hydro that there is still room for further advances in steam economy, while hydro efficiency has practically reached the ultimate, with the present 92 or 93 per cent efficiency obtainable in hydraulic prime movers. This sort of statement is only partly true and is misleading. It is true that there is room for further improvement with respect to thermal efficiency in steam plants, and some such improvement will no doubt take place in the near future. The economic benefits of this improvement will be partially offset by the gradual upward trend of fuel prices. It is true that the efficiency of waterwheels and generators has practically reached the theoretical limit, but this does not by any means indicate that the ultimate economy in hydro construction has been reached. The machinery installation represents only 10 or 15 per cent of a hydro plant; there is still an opportunity for improvement in the economic efficiency of hydraulic installations by improvement of designs of hydraulic structures, by elimination of unnecessary refinements and, greatest of all, by improvement in methods of planning and executing hydro-electric construction. The most modern hydro plant designs tend toward extreme simplicity, and more thought than ever before is being given to the cost of hydraulic structures and to the elimination of non-essentials.

Steam plant construction is relatively simple; the procedure can be standardized to some extent. A hydro-electric project presents the most difficult problems imaginable in organization and management, difficult because each project has its own individual peculiar problems which must be solved without the guide of precedent, and it is possible to standardize and systematize only to a very limited extent. These projects are nearly always managed in a creditable manner, but even where the performance has been unusually creditable, after the work is finished those connected with it can see where it might have been done more efficiently. Here, rather than in the design of machinery, is where there is room for improvement in hydro development. Because of the fact that so large a percentage of the cost of a hydro-electric project is in structures rather than in machinery, it is obvious that there is no economy in buying anything but high-grade machinery, in order that full utilization may be made of money invested in structures.

### Hydro Economy Must Come Through Construction

If a hydro plant which could be built for $3,000,000 costs $4,000,000, no amount of effort expended in scientific design of the waterwheel and generator can make it a perfect plant. Even with the machinery 100 per cent efficient the plant could never attain more than 75 per cent commercial efficiency. Commercial efficiency, in its broadest sense, is the thing to be achieved. The simplification of hydro construction is being, in part, attained by carrying out the idea that a given amount of money which is available for reserve or for protection can be spent to better advantage by installing an additional plant or unit, rather than by partial duplication of equipment in a number of plants.

The present marked increase in the proportion of steam to hydro in Western construction programs will tend to lessen the danger of communities being stampeded into disastrous public ownership ventures. The alleged "romance" is departing from hydro-electric engineering and construction. Certainly there is no romance connected with the financing of a hydro project. When this is thoroughly understood by the general public, and it becomes generally known that with very few exceptions steam generation usually enters into a truly economical scheme of things, there will be less encouragement given to the proponents of state ownership of power. With the fallacy of "harnessing the waterfall" almost at no cost exploded, there is little romance left. A man seeking office would not get many votes if he told the public that if elected he would build a steam plant with their money; somehow it has no appeal to them. In possession of the true facts they are no more likely to vote in favor of the state going into the power business than they would be to vote for state ownership of grocery stores or filling stations.

## Automatic Substation Inspections

By O. M. Ward
*Assistant Electrical Engineer Milwaukee Electric Railway & Light Company, Milwaukee, Wis.*

THE IMPORTANCE of detailed inspections of equipment in automatic substations is evidenced by the inspection report form reproduced below, in use on the system of the Milwaukee Electric Railway & Light Company. These inspections are made at intervals of one week and the reports are made in duplicate, one copy going to the chief operator and the other kept at the substation for reference in future inspections.

*Items Checked on Inspection Report of Automatic Substations*

Station. Date. *Master Element*—Contacts. Mechanical operation. *Time Delay Starting Relay*—Contacts. Mechanical operation. Time setting. *Master Relay*—Contacts. Mechanical operation. *Master Contactor*—Contacts. Mechanical operation. *Starting Contactor or Breaker*—Mechanical operation. Main contacts. Interlock contacts. *Auxiliary Relay for No.* — Contacts. ## Generator Rotor Assembly Improved by Bolt-Stretching Device

A HYDRAULIC machine for tightening the long axial bolts that extend through the rotors of large high-speed turbo-generators has recently been developed by the Westinghouse Electric & Manufacturing Company and has been in successful operation for several months.

*Hydraulic service tightens rotor through-bolts*

The rotors are composed of rolled or forged steel plates and forged shaft ends held together by long axial bolts. This construction permits the rigid inspection and test of materials necessary to safeguard the machine for high operating speeds. Previous to the use of such large rotors these axial bolts were tightened by measuring the torque applied to the nut, and later, as an added precaution, the elongation of the bolt from relaxed to loaded conditions was carefully measured. Variation in friction, either under the seat of the nut or in the threads, caused a variation in the pounds pull required to obtain the required stretch; also, the use of the wrench was awkward.

To remedy this difficulty the hydraulic machine was built with two diametrical pulling heads which permit simultaneous stretching of two opposite rotor bolts. Each pulling head of this inverted press can exert a force of 1,000 tons. The carriage is movable and can be changed for different lengths of rotors. The motors and pumping equipment are located beneath the floor.

After the rotor is assembled temporary through-bolts are inserted. One bolt is removed at a time and the longitudinal hole reamed to an exact bore. The finished bolt is then inserted and the nuts tightened by hand sufficiently to lift the rotor. The rotor is then brought to the pulling machine. Nuts are run up until they just touch their seat, which leaves a portion of the threaded bolt still exposed. The rotor can be raised, lowered or turned by various supports. The end of one piston is visible, in the accompanying illustration, projecting through the end head, and an adapter connects the end of the piston to the threaded portion of bolt extending past the loosely run-up nut. Two diametrical bolts are pulled up to 40 per cent of final load, the nuts tightened until they relieve the stretcher of this tension, and the adapters are then removed. The rotor is turned and two more bolts treated in the same manner. Means are provided to prevent overloading the bolt.

This procedure is continued, gradually tightening the bolts in pairs until 125 per cent normal load is carried. The overloading irons out any irregularities in the structure. The rotor is then removed from the stretching machine and slotted for windings. Following this operation the rotor returns to the stretcher and the tension on the bolts is released to normal. Careful record is kept of the stretch of each bolt while in the machine and each stud is numbered for future reference.

## Shooting Slag Off Boiler Tubes

IN CONNECTION with the operation of the pioneer mercury boiler at the Dutch Point station of the Hartford Electric Light Company with pulverized coal fuel trouble was experienced last year from slag accumulation on the tips of the boiler tubes, with resultant choking of gas passes. These tubes are mounted directly above the heart of the combustion chamber, the tips being exposed to intense heating, and after shut-down the experiment was tried at the suggestion of T. H. Soren, vice-president of the company, of shooting the slag off the tube tips. Forty-six loads of No. 6 shot were fired at the mass from a shotgun, with the result that the slag was completely broken up. Following these tests on a cold boiler and setting, the shotgun was later used on a boiler in service and served to remove dense masses of slag, threatening shut-downs. It was found by these experiments that at the temperatures attained by the metal of the boiler tubes the ordinary shell load gave too high a muzzle velocity to the shot charge, with a consequent tendency to dent the tubes. The Remington Arms Company, Bridgeport, Conn., co-operated in the development of a shell to give a lower muzzle velocity, and no further difficulty occurred in the way of denting. This method of slag removal has proved thoroughly successful.

## Heavy Equipment Handling Simplified by Derrick Truck

By D. A. Hord
*Superintendent of Distribution Northwestern Electric Company, Portland, Ore.*

ONE of the most useful pieces of equipment of the distribution department of the Northwestern Electric Company, Portland, Ore., is the truck-tractor derrick shown in the accompanying illustrations. The derrick, which was designed by the company, is entirely of structural steel with incidental steel castings. The chassis was made by General Motors and is its standard 10-ton truck-tractor, type L-10T.

The derrick is constructed to allow clearance for the gooseneck coupling of a trailer which is used for hauling heavy equipment. The framing of the derrick is so made that the mast gudgeon is directly over and coincident with the rear axle center line, giving great lifting stability. With the boom straight back and set for a 10-ft. radius it is impossible to tip the truck over when lifting the capacity load of 3 tons. The truck and derrick are utilized for many purposes, including loading, unloading and hauling poles and other material and equipment. The total cost of the equipment as shown was approximately $12,000.

# Distribution Planning*

Methods of calculating the economical characteristics of electrical distribution systems, particularly transformer spacing and sizes of line conductor

By W. R. Bullard
*Electric Bond & Share Company, New York City*

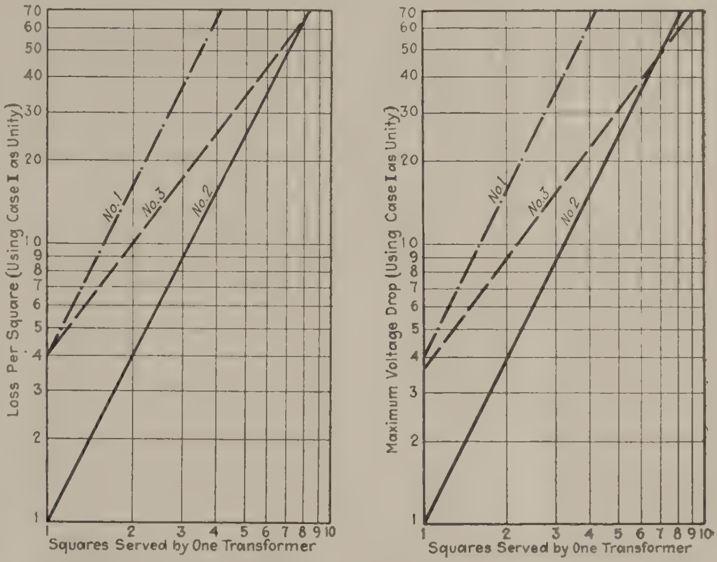
IN CONSIDERING the characteristics of the secondary distribution system where the conductors have branches or network arrangements of feed simple empirical relations between transformer spacing, energy loss and voltage drop are developed. These relations are used in the development of equations of economics similar to those previously given for straight line feeds.

Where the low-voltage mains do not consist of a simple straight line of circuit the conditions are somewhat more complicated. For any particular arrangement of branches or network feeds the voltage drop and power loss can of course be calculated by means of Kirchoff's laws. Such calculations, however, lead into extremely complicated equations that are not applicable in practice to calculations of the economics of transformer spacing and copper sizes. However, a comparatively simple empirical relation between transformer size, voltage drop and power loss in a network of conductors can be derived by assuming a network formed by the intersecting streets of a district in which the blocks are exactly square, then taking several symmetrical spacings of transformers and calculating the voltage drop and power loss for each spacing.

Fig. 3 shows ideal transformer spacings for serving secondary networks from street intersections. Fig. 4 shows the same thing for cases where the transformers are placed at intermediate locations between street intersections, and Table I gives the relative values of voltage drop and power loss for the different cases shown in Figs. 3 and 4.

TABLE I

| Case No. | No. of Squares per Transformer | Type of Feed | Maximum Current in Line | Maximum Voltage Drop | Copper Losses per Square for Fixed Cross Section |
|---|---|---|---|---|---|
| 1 | 1 | Four way | 1 | 1 | 1 |
| 2 | 2 | Four way | 2 | 4 | 4 |
| 3 | 4 | Four way | 4 | 16 | 16 |
| 4 | 8 | Four way | 8 | 32 | 40 |
| 5 | 1 | Two way | 2 | 4 | 4 |
| 6 | 2 | Two way | 4 | 8 | 10 |
| 7 | 4 | Two way | 8 | 24 | 28 |
| 8 | 8 | Two way | 16 | 48 | 64 |



*Figs. 1 and 2—Power loss and maximum voltage drop in secondary mains*

(One square is equivalent in length to two blocks)
No. 1—Two-way straight line feed. No. 2—Four-way network feed.
No. 3—Two-way network feed.

Values thus obtained, when plotted on logarithmic paper as voltage drop or power loss versus the number of squares served by a single transformer, will within a reasonable range of values give a straight line. (See Figs. 1 and 2.) These lines, when interpreted, give exponential relations between the quantities that are mentioned.

Since the quantities involved are considerably different where transformers are located at street intersections and feed in four directions than where they are located between street intersections and feed in only two directions, two different sets of relations must be derived. Curves 3 in Figs. 1 and 2 are for the case where transformers feed in two directions only and show that, for the range between one square and eight squares served by each transformer, the power loss per square and maximum voltage drop are approximately proportional to the four-thirds power of the number of squares served.

Curves 2 are for the case where each transformer is located at a street intersection, and in this case, for the same range as before stated, the voltage drop and power loss are proportional to the square of the number of

---

**The first article of this series appeared in* Electrical World, *March 10, 1928; the second, March 24, 1928. The fourth and last article will be published in an early issue.*

squares served, or, in other words, to the square of the size of each transformer. The larger exponent in this case is due to the fact that where the transformer feeds in four directions there are a larger number of straight line feeds and a less number of branch feeds, thus making this case almost the same as the straight line feed relation before described. Curves 1 are for a straight line feed and are included merely for comparison.

Reducing these theoretical relations to practical form and allowing a 100 per cent factor of safety, as in the previous case, we have the following equations, the second two of which contain a new term—namely $L$, which represents the length of block between the street intersections in 100-ft. units. This term, of course, applies to blocks that have the same dimensions in each direction—that is, square blocks—but the formulas will generally apply, in the case of rectangular blocks, if $L$ is expressed in terms of the average length of block for both directions.

Four-way feed:

$$W = \frac{0.04575\, I_T^2}{1{,}000\, a} \tag{1}$$

$$V = \frac{0.0685\, I_T^2}{aD} \tag{2}$$

Two-way feed:

$$W = \frac{0.2905\, D^{2/3} L^{2/3} I_T^{4/3}}{1{,}000\, a} \tag{3}$$

$$V = \frac{0.391\, L^{2/3} I_T^{4/3}}{aD^{1/3}} \tag{4}$$

Due to the considerably lower voltage drop and power loss where transformers are located at street intersections and feed in four directions, it is of considerable advantage so to locate them when physical conditions will permit. This arrangement can usually be utilized in underground systems, particularly when separate transformer vaults under the street surface are used, these being located a few feet away from the street intersections, but connected to the four-way intersections of low-voltage mains by short lengths of heavy conductors. In overhead systems, however, due to congestion of lines, it is the usual practice not to install transformers on poles at street intersections, but rather to locate them on poles intermediate between the intersections. Therefore in general the four-thirds power relations given in the above equations are generally applicable to overhead systems, whereas the square relations (for four-way feeds) are generally applicable to underground systems.

In developing equations of economics of transformer spacing and copper size for cases where transformers feed individual small networks of copper the cost of primary must be taken into consideration, since, generally speaking, the amount of primary in the case of a distribution network varies with the number of transformers.

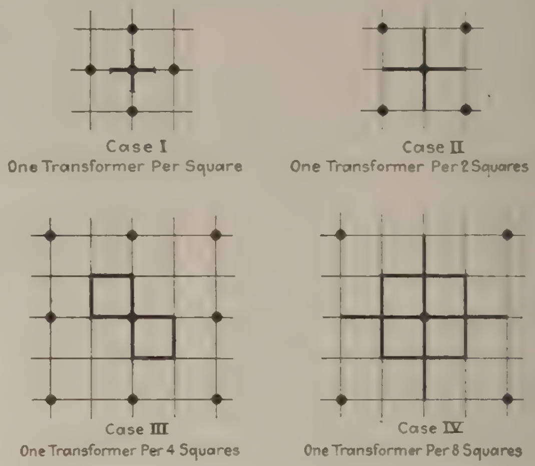
By plotting typical cases of transformer spacing it can easily be shown that the amount of primary laterals varies as the square root of the number of transformers or inversely as the square root of the size of the transformers.

If $C_3$ equals the annual fixed charges on the cost of primary per 100 ft. of circuit (including an allowance for additional pole height, additional hardware, insulators, etc.), then the annual cost of primary per 100 ft. of secondary in a radial system is given by the expression

$$0.707\, C_3 \sqrt{\frac{LD}{I_T}}$$

where $L$ is the average distance between street intersections in 100-ft. units.

This expression does not take into account the cost of losses in primary laterals, but the latter are usually proportionately small in systems where the load configuration is such as to require network feeds. And in practically any case no great error will be introduced by neglecting these losses. The derivation of equations for economics of copper size and transformer spacing in network feeds using the above expression for primaries is given later in this article.



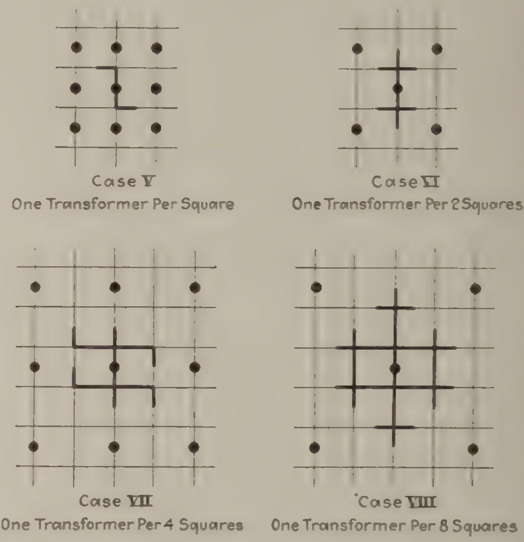
Case I
One Transformer Per Square

Case II
One Transformer Per 2 Squares

Case III
One Transformer Per 4 Squares

Case IV
One Transformer Per 8 Squares

*Fig. 3—Symmetrical arrangement of transformers placed at street intersections*



Case V
One Transformer Per Square

Case VI
One Transformer Per 2 Squares'

Case VII
One Transformer Per 4 Squares

Case VIII
One Transformer Per 8 Squares

*Fig. 4—Symmetrical arrangement of transformers placed between street intersections*

In a multiple feed network system with interlaced primaries the amount of primary lateral is dependent upon the number of feeders. However, the application of the equations derived by the use of the above expression to such a network system can easily be corrected by multiplying the estimated value of $C_3$ by $\left(1 + \frac{X - 1}{4}\right)$ where $X$ is the number of primary feeders serving a single network. The expression $\left(1 + \frac{X - 1}{4}\right)$ is empirical, but will give very nearly correct values where the interlacing of primaries is thoroughly carried out.

In a multiple feed network system with solidly interconnected secondary mains care should be taken to insure that the system characteristics selected are not such as to prevent burning off low-voltage short circuits. With thoroughly bonded cables of ordinary sizes installed in ducts sufficiently large to avoid undue crowding, it can be assumed that even a solid copper-to-copper short circuit will clear itself if sufficient current can flow to open the metallic circuit. Tests have indicated that the voltage drop along the conductor under short-circuit conditions should exceed 6 volts per 100 ft. to melt soldered joints, or 24 volts per 100 ft. to fuse the conductors. (See "Underground Alternating-Current Network Distribution for Central Station Systems," by A. H. Kehoe, *Journal A. I. E. E.*, June, 1924.) The proper value to insure the self-clearing feature of the network probably lies between these two limits. If the intermediate value of 15 volts per 100 ft. is selected, then the transformer spacing on simple straight line feeds is limited to something less than 770 ft. for systems with 115 volts nominal between line and neutral. The exact maximum allowable spacing would depend upon the relative amount of transformer and primary circuit impedance with respect to that of the low-voltage cables.

The equations for economical transformer spacing and secondary copper sizes will now be developed.

The cost of losses in the secondary conductors equals $WnfC$.

The fixed charges on cost of secondary copper equal $C_2n_1a$.

The fixed charges on the transformer installations and the cost of losses in the transformer equal $\frac{C_1D}{I_T}$

The fixed charges on the primary equal

$$0.707\,C_3\sqrt{\frac{LD}{I_T}}$$

The total annual cost of 100 ft. of secondary system equals

$$WnfC + C_2n_1a + \frac{C_1D}{I_T} + 0.707\,C_3\sqrt{\frac{LD}{I_T}} \qquad \textit{(Formula b)}$$

Only those costs which vary with the size of copper and transformer spacing are included in the above formula.

### Economics of Four-Way Network Feed

Substituting the value of $W$ from equation 1 in formula $b$ we have:

$$\text{Total cost} = \frac{0.04575\,I_T^2}{1{,}000\,a} + C_2n_1a + \frac{C_1D}{I_T} + 0.707\,C_3\sqrt{\frac{LD}{I_T}} \qquad \textit{(Formula c)}$$

*For Complete Economics.*—A size of secondary conductor must be found that reduces the sum of the cost of copper losses and fixed charges on copper to a minimum with a given value of $I_T$.

By equating the derivative of $\frac{0.04575\,I_T^2}{1{,}000\,a} + C_2n_1a$ with respect to $a$ to zero and solving for $a$ we get:

$$a = 0.00676\,I_T\sqrt{\frac{nfC}{n_1C_2}} \qquad (5)$$

Substituting the expression in formula $c$, we have:
Total cost =

$$0.01352\sqrt{nn_1fCC_2}\,I_T + \frac{C_1D}{I_T} + 0.707\,C_3\sqrt{\frac{LD}{I_T}}$$

Differentiating the total cost with respect to $I_T$ and equating to zero, we have an expression of the form:

$$A_2 = I_T^2 - B_2I_T^{1/2} \qquad (6)$$

where $$A_2 = \frac{74\,C_1D}{\sqrt{nn_1fCC_2}} \qquad (7)$$

and $$B_2 = \frac{26.15\,C_3\sqrt{LD}}{\sqrt{nn_1fCC_2}} \qquad (8)$$

Graphical solutions for equation 6 and subsequent working equations will be given in the fourth of this series of articles.

*If Voltage Drop Determines the Size of Conductors.*—If it is desired to design a system for the most economical characteristics that will give a certain voltage drop, we have, by substituting the value of $a$ from equation 2 $\left(a = \frac{0.0685\,I_T^2}{DV} \text{ equation 9}\right)$ in formula $c$ and differentiating:

$$\frac{d(\mathit{Total\ Cost})}{d(I_T)} = \frac{0.137\,C_2n_1I_T}{DV} - \frac{C_1D}{I_T^2} - \frac{0.3535\,L^{1/2}D^{1/2}C_3}{I_T^{3/2}}$$

Equating to zero, we get an expression of the form:

$$A_3 = I_T^3 - B_3I_T^{1/2} \qquad (10)$$

where $$A_3 = \frac{7.3\,C_1VD^2}{n_1C_2} \qquad (11)$$

and $$B_3 = \frac{2.58\,C_3VL^{1/2}D^{3/2}}{n_1C_2} \qquad (12)$$

*If Current-Carrying Capacity Limits the Size of Conductors.*—If the current in the secondary nearest to the transformer, $\frac{I_T}{4}$, derived from the above equations exceeds the current-carrying capacity of the conductor, the equations must be applied which are derived by first limiting the size of $a$ to the proper function of $I_T$ from a heating standpoint.

The value of $a$ when it is limited by temperature in underground conductors is given approximately by

$$a = \frac{I_T^2b}{160{,}000} \qquad (13)$$

Substituting the value of $a$ from equation 13 in formula $c$ and differentiating, we have:

$$\frac{d(\mathit{Total\ Cost})}{d(I_T)} = \frac{C_2n_1bI_T}{80{,}000} - \frac{C_1D}{I_T^2} - \frac{0.3535\,L^{1/2}D^{1/2}C_3}{I_T^{3/2}}$$

Equating to zero, we get an expression of the form

$$A_4 = I_T^3 - B_4I_T^{1/2} \qquad (14)$$

where $$A_4 = \frac{80{,}000\,C_1D}{C_2n_1b} \qquad (15)$$

and $$B_4 = \frac{28{,}280\,C_3\sqrt{LD}}{n_1bC_2} \qquad (16)$$

### Economics of Two-Way Network Feed

Substituting the value of $W$ from equation 3 in formula $b$, we have for the total cost:

$$\frac{0.2905\,nfCD^{2/3}L^{2/3}I_T^{4/3}}{1{,}000\,a} + C_2n_1a + \frac{C_1D}{I_T} + 0.707\,C^3\sqrt{\frac{LD}{I_T}} \qquad \textit{(Formula d)}$$

*For Complete Economics.*—The size of secondary conductors $a$ must be found that will reduce the sum of the cost of copper losses and fixed charges on copper to a minimum with a given value of $I_T$.

By equating the derivative of $\frac{0.2905\, nfCD^{2/3}L^{2/3}I_T^{4/3}}{1{,}000a}$ $+ C_2n_1a$ with respect to $a$ to zero and solving for $a$ we get:

$$a = 0.01703 \sqrt{\frac{nfC}{n_1C_2}}\, D^{1/3}L^{1/3}I_T^{2/3} \qquad (17)$$

Substituting this expression in formula $d$, we have

$$\text{Total cost} = 0.0341\sqrt{nn_1fCC_2}\, D^{1/3}L^{1/3}I_T^{2/3} + \frac{C_1D}{I_T} + 0.707\, C_3\sqrt{\frac{LD}{I_T}}$$

Differentiating the total cost with respect to $I_T$ and equating to zero, we have an expression of the form:

$$A_5 = I_T^{5/3} - B_5I_T^{1/2} \qquad (18)$$

where $$A_5 = \frac{44\, C_1}{\sqrt{nn_1fCC_2}}\left(\frac{D^{2/3}}{L^{1/3}}\right) \qquad (19)$$

and $$B_5 = \frac{15.58\, C_3L^{1/6}D^{1/6}}{\sqrt{nn_1fCC_2}} \qquad (20)$$

*If Voltage Drop Determines the Size of Conductors.*—If it is desired to find the most economical characteristics that will give a certain voltage drop, we have, by substituting the value of $a$ $\left(a = \frac{0.391\, L^{2/3}I_T^{4/3}}{VD^{1/3}} \text{ equation 21}\right)$ from equation 4 in formula $d$ and differentiating:

$$\frac{d(\mathit{Total\ Cost})}{d(I_T)} = \frac{0.521\, C_2n_1L^{2/3}I_T^{1/3}}{VD^{1/3}} - \frac{C_1D}{I_T^2} - \frac{0.3535\, L^{1/2}D^{1/2}C_3}{I_T^{3/2}}$$

Equating to zero, we get an expression of the form:

$$A_6 = I_T^{7/3} - B_6I_T^{1/2} \qquad (22)$$

where $$A_6 = \frac{1.92\, VC_1D^{4/3}}{n_1C_2L^{2/3}} \qquad (23)$$

and $$B_6 = \frac{0.678\, C_3VD^{5/6}}{n_1C_2L^{1/6}} \qquad (24)$$

*If Current-Carrying Capacity Limits the Size of Conductors.*—If the current in the secondary nearest to the transformer exceeds the current-carrying capacity of the conductors, then equations must be applied that are derived by first limiting the size of $a$ to the proper function of $I_T$, from a heating standpoint.

The value of $a$ when it is limited by temperature in overhead conductors is given by:

$$a = \frac{I_T^{4/3}b}{1{,}170} \qquad (25)$$

Substituting the value of $a$ from equation 25 in formula $d$ and differentiating, we have:

$$\frac{d(\mathit{Total\ Cost})}{d(I_T)} = \frac{4\, n_1bC_2I_T^{1/3}}{3 \times 1{,}170} - \frac{C_1D}{I_T^2} - \frac{0.3535\, L^{1/2}D^{1/2}C_3}{I_T^{3/2}}$$

Equating to zero, we get an expression of the form:

$$A_7 = I_T^{7/3} - B_7I_T^{1/2} \qquad (26)$$

where $$A_7 = \frac{877.5\, C_1D}{C_2n_1b} \qquad (27)$$

and $$B_7 = \frac{310\, C_3}{C_2n_1b}\sqrt{LD} \qquad (28)$$

# Broken Insulators Withstand Normal Voltage

By R. Rader
*Office Engineer Puget Sound Power & Light Company,* Seattle, Wash.*

To test the ability of modern pin-type insulators for operating voltages of 50-70 kv. to withstand normal voltage after the shells have been broken off, a condition which may obtain under operating conditions due to rocks being thrown at insulators or the petticoats being shot off, the Puget Sound Power & Light Company tested a few standard types for wet and dry flashover under this extreme condition. New insulators of five makes were selected and the shells broken off with hammer blows. Each type was treated as nearly equally as possible, as shown by the accompanying illustration. One of the specimens was exceptionally brittle.

*Pin-type insulators stripped of shells and subjected to flashover tests to simulate line conditions which may obtain*

After stripping, the remains were subjected to dry and wet flashover tests in accordance with A.I.E.E. standards. The wet tests were conducted after the dry tests had been completed and after the insulators had been sprayed with water for five minutes while in an upright position. The initial voltage for the dry tests was 30,000 volts, which was raised in increments of 1,000 volts per second until flashover occurred. The wet tests began at 15,000 volts, the voltage being increased at the same rate as in the dry tests. Results are given in the following table:

| Insulator (Reading from Left to Right in the Illustration) | Dry Flashover Voltage | Wet Flashover Voltage |
|---|---|---|
| No. 1 | 73,500 | 39,000 |
| No. 2 | 72,000 | 32,000 |
| No. 3 | 72,000 | 31,000 |
| No. 4 | 73,000 | 35,000 |
| No. 5 | 73,000 | 32,000 |

The dry flashovers show a remarkable uniformity, as opposed to the wet flashover values. It seems that the insulator design has much to do with the flashover values even with the shells removed. The company's standard specifications now contain the clause: "The general design of insulators shall be such that when all the outer rims are stripped off by breakage the insulators will not have a wet flashover value less than maximum operating voltage of the classification specified."

# Useful Nomogram for Photometric Work

By Hempstead S. Bull
*Instructor in Electrical Engineering*
*University of Michigan*

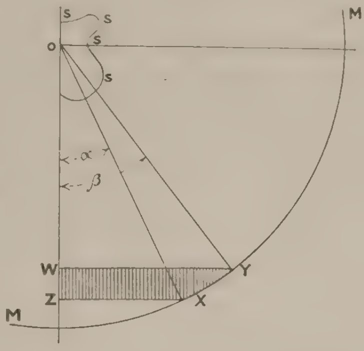
The accompanying chart provides a means of obtaining the zonal lumens output of a luminaire when its polar candle power distribution curve is available. This method possesses, in addition to the inherent advantages of all nomographic charts, a feature in common with the Rousseau diagram which facilitates accurate work, in that zones of varying central-angular width may be selected to conform to the irregularities of the candle power curve.

In the figure is shown half of a typical candlepower distribution curve *S*. Let *M M* be a portion of the surface of a sphere inclosing the light source and with its center at the center of the light, *O*.

*OX* and *OY* are the traces of two coaxial cones making angles *a* and *b* respectively with the axis. It is known that the solid angle at *O* subtended by the zone *XYWZ* on the surface of the sphere is equal to 2 (cos α—cos β).

To obtain the lumens output in this zone it is necessary to multiply the solid-angular content of the zone in steradians by the average candlepower for the zone as obtained directly from the candlepower distribution curve. This process can be carried out graphically on the accompanying nomogram.

Scales *A*, *B* and *C* form a subtraction chart by which the quantity (cos α—cos β) can be determined for any values of α and β. The value of this quantity can then be transformed to steradians by multiplying by 2, which process is performed by projecting from *P* through the value on scale *C* to scale *D*. Scales *E*, *F*, and *G* form a multiplication chart by which the product of steradians times average candlepower can be carried through to obtain zonal lumens. It is merely necessary to set the value of steradians on scale *E* as soon as it is obtained on scale *D*, and the candlepower value on *F*, and read lumens output on *G*.



*Typical candlepower distribution*

For example, let the values of α and β be 15 deg. and 30 deg. respectively. Line 1 drawn through these points on scales *A* and *B* cuts *C* at 0.10 and line 2 drawn from *P* through 0.10 on *C* cuts *D* at 0.63. Line 3 drawn from the value 0.63 on scale *E* to the value of the average candlepower for this zone, which was here assumed to be 90, cuts scale *G* at 56.5, which is the value of lumens emitted in this zone.

The original of the accompanying chart covers most of a 12 x 19 sheet. For the information of any one wishing to reproduce this chart to the original scale the dimensions of the various scales used are given below.

---

**Computation of Zonal Lumens**

1. *Locate the zonal bounding angles α and β on scales* ***A*** *and* ***B****. Connect them with a straight line and mark intersection on scale* ***C***
2. *Project a line from* ***P*** *through this intersection to scale* ***D*** *and read steradians in zone*
3. *Locate this value of steradians on* ***E*** *and the average zonal candle-power on* ***F*** *and connect them. The intersection on* ***G*** *indicates the lumens in the zone*

*A*—total length 10 in., distance from 90 deg. to 85 deg. = 0.87 in., which corresponds to 0.0872, the value of cos 85 deg.

*B*—similar to *A*, but inverted.

*C*—total length 5 in. divided into 100 equal parts. Distance *A* to *C* = *C* to *B* = 4.75 in.

*D*—total length, 8.3 in. divided into 62.8 equal parts.

Distance *D* to *C* = 3.75 in.

Perpendicular distance *P* to *C* = 5.63 in.

*E*—a 5-in. logarithmic chart, total length 10.48 in.

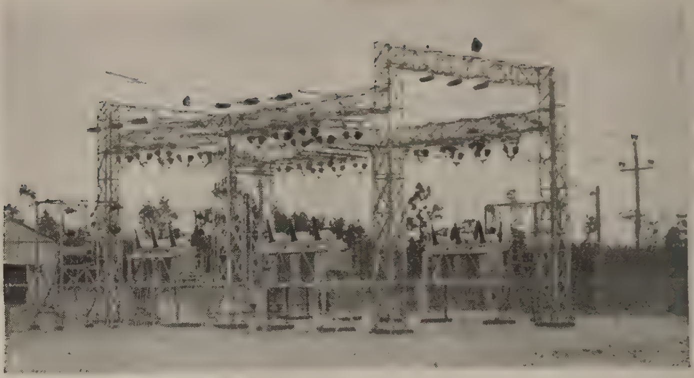
*F*—a 5-in. logarithmic chart, total length 10.48 in.

*G*—a 2.5-in. logarithmic chart, total length 10.48 in.

Distance *E* to *G* = *G* to *F* = 4.5 in.

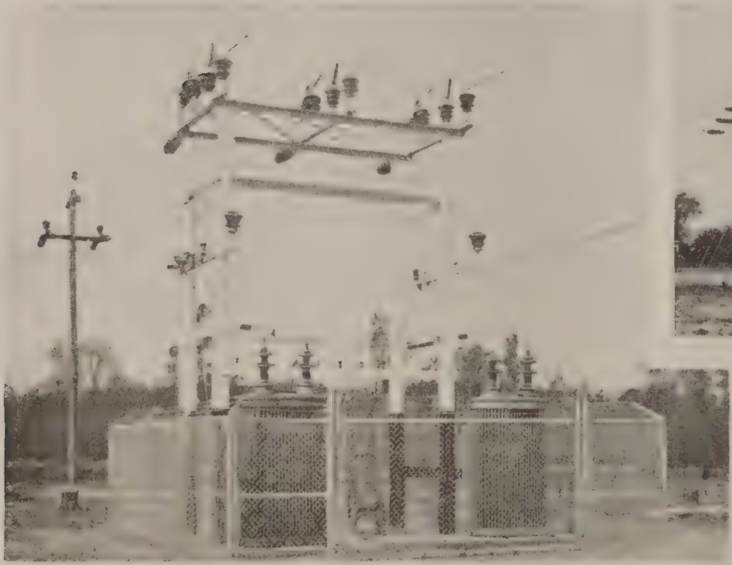
*Nomogram permits rapid calculation of zonal lumens when distribution and candlepower are known*

# *Construction Practices on Florida-Georgia Lines*



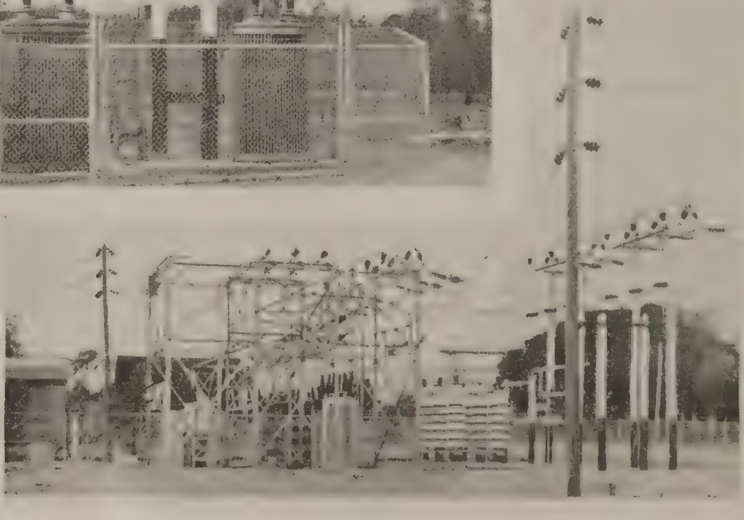
*Standard 66-kv. steel switching structure at Croom, Fla.*

THE methods of erecting the new Southern lines of the National Public Service System were described by M. J. Idail and C. E. Bland in the March 17 issue of ELECTRICAL WORLD. The structures used for substations, 110-kv. transmission towers and 66-kv. pole lines vary with local conditions and representative types are shown in the accompanying illustrations. In order to keep the standard of service in step with the increased load, certain existing lines were reinforced and revamped. The interconnection of relatively small isolated properties and the new 25,000-kw. base-load power station at Inglis was accomplished in this construction program. After the completion of this work there were more than 730 miles of 66-kv. line and 178 miles of 110-kv. trunk line.

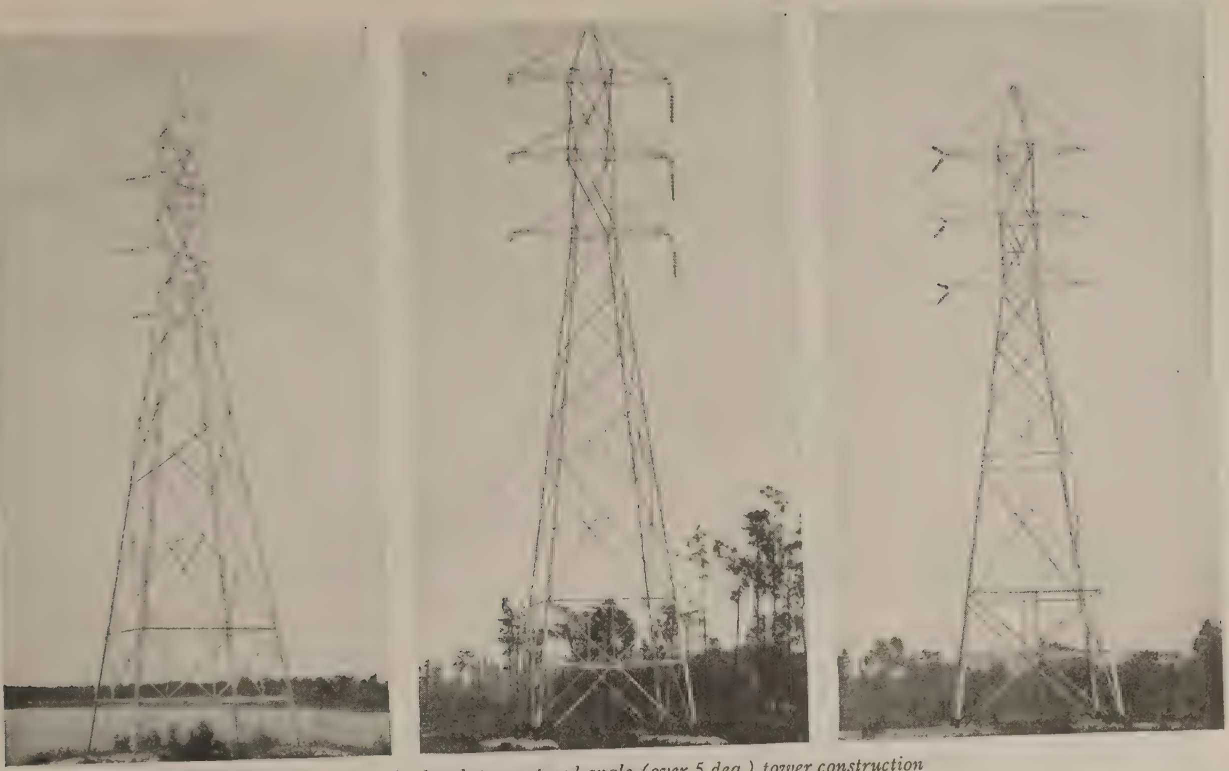


*Standard 66-kv. wood-pole substation at Inverness, Fla.*

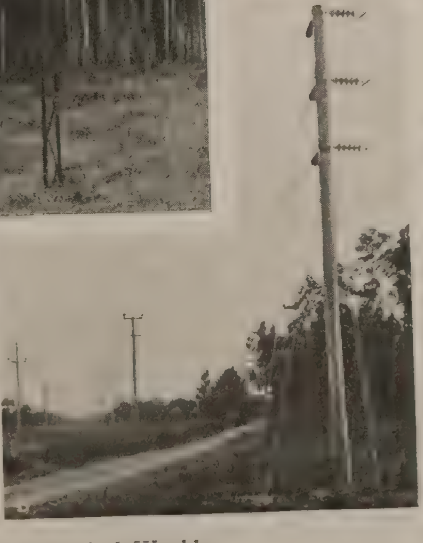
*66-kv. switching station at Wildwood, Fla.*



*Combination wood and steel station under construction at Leesburg, Fla.*



*110-kv. dead-end, tangent and angle (over 5 deg.) tower construction*



*A — 44-kv. steel pole line rebuilt for 66-kv.*

*B—Standard line sectionalizing switch*

*C — Typical 66-kv. long-span construction*

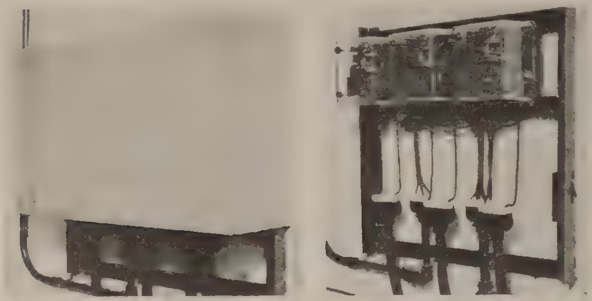
*D—66-kv. wood-pole line*

*E — 66-kv. road crossing showing dead-end construction*

## Transformer Vault Relay Protection

IN MANY of the transformer vaults of the distribution network of the Dallas Power & Light Company which may possibly be flooded the relays controlling the automatic operation of the network switches are provided with open bottom covers that are, in effect, diving bells. If a vault becomes filled with water the cover will entrap enough air to prevent the water from reaching the relays.

It is not always wholly satisfactory to inclose the relays in air- and water-tight cases because of the effect of temperature rise due to lack of ventilation. Ventilation is provided by the open bottom cover and it is just as effective in keeping the relays out of the water as a closed case would be.



*Underground network relays protected from water by welded steel case*

The accompanying illustrations show the manner in which the cover is used and a close inspection of the pictures will reveal the gravity latches which hold the cover in place as the water rises in and around it.

## Utility Training Course for College Graduates

TWO training courses for college graduates have been established by the Puget Sound Power & Light Company with the object of selecting a limited number of graduates from recognized universities from which to develop suitable material to fill permanent positions in the organization from time to time. One is an engineering apprentice course and the other is a course in business administration. The company will make selections for both courses from students who expect to graduate in June and who file applications prior to specified dates early in the calendar year.

The engineering course will cover a period of three years with allotment of time according to the following schedule:

| | Months |
|---|---|
| 1. Testing and inspection—service division | 6 |
| 2. Engineering plans | 8 |
| 3. Construction and installation | 8 |
| 4. Operation and maintenance | 6 |
| 5. Sales, accounting and statistical | 6 |
| 6. Elective | 2 |
| Total | 36 |

Applicants selected will be started at $100 per month and their salary will be adjusted at the end of each six months on a merit rating basis. Men will be rated from 70 to 130 per cent of a normal average. A rating of 80 per cent will be necessary for the man to continue in the company's employ at the same salary, 100 per cent will entitle him to an increase of $5 per month and a rating of 120 per cent or over will entitle him to an increase of $10 per month.

The business administration course will cover a two-year period with time divided as follows:

| | Months |
|---|---|
| 1. Purchasing and stores | 4 |
| 2. Sales | 2 |
| 3. Customers' billing | 3 |
| 4. Credit and collections | 2 |
| 5. Accounting | 6 |
| 6. Insurance department | 1 |
| 7. Corporate subjects | 5 |
| 8. Personnel department | 1 |
| Total | 24 |

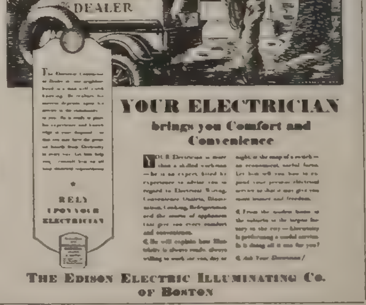
Students in the business administration course will be started at a salary of $90 per month, which will be subject to adjustment as merited during the period of training. At the end of the period of each course the company is under no obligation to give permanent employment, but will give first consideration to those who have made satisfactory records in the courses. If desired, the company will give a student a certificate on its letterhead setting forth the time spent in each subdivision of the course and a statement of the ability, personality and qualifications of the individual.

The proposed courses have been prepared after very careful consideration of similar courses given by other utilities.

## Urges Public Acquaintance with Neighborhood Contractor

ON THIS advertisement run by the Edison Electric Illuminating Company of Boston it says:

> The electrical contractor or dealer in your neighborhood is a man well worth knowing. He realizes his success depends upon his service to the community—to you. He is ready to place his experience and knowledge at your disposal, so that you may have the greatest benefit from electricity in every way. Let him help you; consult him on all your electrical requirements.
>
> Your electrician is more than a skilled workman; he is an expert, fitted by experience to advise you in regard to electrical wiring, convenience outlets, illumination, cooking, refrigeration and the scores of appliances that give you every comfort and convenience. He will explain how electricity is always ready, always willing to work for you, day or night, at the snap of a switch—an economical, useful force. Let him tell you how to expand your present electrical service so that it may give you more leisure and freedom. From the modest home in the suburbs to the largest factory in the city, electricity is performing a useful service. Is it doing all it can for you? Ask your electrician.



# The Purchasing Agent Speaks

A frank discussion of some of the causes of price cutting in this buyers' market. A bit of background and a few suggestions from the head of the purchasing agents' association

By Lewis A. Jones

*Vice-President New York Power & Light Corporation and President of the National Association of Purchasing Agents*

*The subject of price cutting is under very general discussion. For the purpose of crystallizing some of the principles and practices involved, two articles by Earl Whitehorne have been published in recent issues of the* Electrical World, *one entitled "Who Pays the Cost of Price Cutting?" the other "Some Experiences in Price Cutting." Many interesting letters of comment and criticism have been received from both buyers and sellers and will form the basis of further recommendations upon this theme. Meanwhile, this message from the head of the national organization of the purchasing agents is pertinent and interesting as a frank opinion.*

I HAVE read your recent article entitled "Who Pays the Cost of Price Cutting?" It is most interesting. I have a lot of things which I would like to say, but which are difficult to put on paper.

I have no grievance against the sales organizations of the country, but I have many thoughts based upon some sad experiences which I have discussed much and often with venders. Unless carefully expressed, they would carry, perhaps, an impression of a controversial attitude, which I want to avoid. This feeling is based simply upon the fact that I think the day must come when the purchasing agents of the country and the sales organizations will get together and study some of their mutual problems, in a definitely constructive frame of mind. This is as it should be, and this year, as president of the National Association of Purchasing Agents, I have had a definite plan to call together some of the leading industrial executives to discuss this very topic. So much for the preliminaries.

I believe this article to be thoroughly constructive in its intended purpose. Of course, with a just amount of pride in my work, it hurts to have implications made against purchasing agents. I know all too well, however, that there are men in our work who do represent the attitude which you emphasize. These, however, I do earnestly believe are becoming each year fewer in number. Through our national association a vast amount of good is being done to recognize the ethics and economics of the problem.

### A Bit of Background

There are about 8,000 concerns in the country, I believe, whose annual purchases amount to a million dollars or over and who may properly be supposed, therefore, to maintain central purchasing departments. There are nearly 5,000 men holding membership in our national association. About 60 per cent of every transaction is represented by purchase function, 20 per cent sales and 20 per cent executive. In the old days of barter, selling was recognized as the primary function, and in its activity was considered ahead of production and of purchasing. Of necessity, as the industrial picture expanded, sales took precedence over other activities in the minds of the public because of the prominence of advertising. Salesmen also were among the first to organize.

The executives did most of the buying, and later, as industry developed, men or clerks were given the title of "purchasing agent." But they were too often designed by the executive not from the standpoint of efficiency but to give some man a job, or identify a certain part of his business, while he himself still really carried on the activities. There are still examples of this practice, too. The natural result was that sales organizations rebelled at being asked to deal with men having no authority, and in a very natural way were forced, in order to meet the requirements of their own companies, to go over the head of the so-called purchasing agent. Still being handicapped, they began to go into the shops and the factories, to see the foremen, and in every possible way to seek direct contact. In this respect purchasing agents themselves were to blame largely, because instead of working with these men they attempted to establish a position, a dignity and a name which they had not earned, and which the executives had not given them. Instead of working frankly and openly with the salesmen they antagonized them. This practice is still in vogue in many similar fields and is a "thorn in the flesh" of those men in the purchasing work who have a larger vision.

Because of all this, sales organizations have been and are in a great degree very antagonistic to the purchasing work. I well recall at one of our national conventions, when a certain sales organization was asked to provide a speaker on our program, it sent an advertising man to come before us, and he spent the entire time allotted to him in telling us of our faults, condemning our attitudes and emphasizing the high qualifications of salesmanship as against the evil practices of purchasing. Where we had looked for a constructive piece of work and a chance to co-ordinate our activities, we were driven farther apart.

Sales managers today send men out on the road who are very poorly prepared. In my office, for instance, we interview many hundreds of men in the course of a month, and they are a most exceptional lot, I believe, in character and capabilities. And I find that in almost every instance where they are not prepared to give me the information and service which I have a right to expect when I grant an interview, it is almost entirely the fault of the sales manager or the executives back in the home office. My sympathy is completely with the man on the road, who, if his concern functions properly, should be to me the main point of contact and should represent his concern in all that is best of constructive thought, effort and service.

### Need for Authority

When you ask "Who is at fault?" each side will answer that the other man holds the crown. But as I have spent a great many hours in thinking about and discussing this problem, as I have met hundreds of purchasing men at our public utility meetings, at our national conventions, in their private offices, in community work, etc., I have in the last eleven years found a marvelous improvement in the caliber of purchasing men, and great anxiety for the improvement of the ethics of our work. We have a high type of men in every way. From among their number there are being selected today some of the highest executives of industry. For instance, A. L. Salt, for years purchasing agent of the Western Electric, is now the president of the Graybar Electric Company. There are many others. I do not in any way evade or overlook the methods of small-caliber purchasing men, but you will find an equal number or more in the ranks of salesmen.

Who is most at fault, the buyer or the seller? I think it is at least a 50-50 break and needs only a Moses in industry to eradicate 90 per cent of the misunderstandings which exist today. This Moses, however, will have to improve the ethics of selling as definitely as he improves the ethics of buying, and I firmly believe that this can be done through a co-ordinated effort on the part of the executives, working with and through purchasing departments as definitely as they work with their sales organizations.

The trouble is that so many executives give the men the title of "purchasing agent" and then withhold the authority. And I can speak quite frankly here, because in my own work I think I have about the finest situation in this respect that any man could ever hope for.

### A Few Examples

Every transaction between a purchaser and a vender should be on a basis of mutual profit, benefit and satisfaction. Otherwise, sooner or later one or the other will be a loser. The best purchase work can be done on a basis of complete confidence. Three things must be considered: First, the quality of the article to be obtained to best fit the need. Second, the consideration generally covered by the misused word "service," which the vender will give to the purchaser's need. Third, price.

As an example, I am at the present time buying a certain commodity running into many thousands of dollars. Every possible consideration is given to me from the standpoint of providing the proper quality and the vender has gone to extremes in trying to meet our needs. The consideration given to our requirements by way of shipment, etc., is without criticism. But the price, he frankly states, is way below his costs, and we are quite sure that this is true. Still, we buy, though in the usual meaning it is an unethical situation. However, it happens to be a very special case, because this concern is shipping its product to myself and others at a loss, and in doing so is following an established policy. But he is fighting for the establishment of a certain principle of business conduct, and if he wins we will win in the long run. And while at the moment it is an unethical transaction as most men will view it and we are reaping the benefit of what he claims to be too low a price, there will come a time when we will be asked to, and should, work with him to help equalize the situation. As a purchasing agent I believe I owe that man a definite responsibility, if I accept the situation which he offers now, to go through with him to the end.

You emphasize the fact that we are now in a buyers' market and have compared activities of purchasing agents now to comparable activities of salesmen when there is a sales market. But even in a buyers' market such as we now have a large part of the trouble, I firmly believe, is caused by the producing agencies themselves, a weakness which you have designated as "lack of price courage." For instance, a few months ago I had a special piece of apparatus to buy. It had to be made up. I asked for bids, and then one day the executive of one of the companies came in to see me. Recognizing the extreme pressure and competition which was on, I told this man that before I asked for my file of prices, which I had not checked through, I wanted to know whether or not he had given me what he considered an equitable price and the best which he had to offer, because I did not propose to "horse trade" with him. I wanted each man whom I had asked to bid to be given an equal opportunity at the business, and the fact that this man sat at my desk would have no bearing whatever on the final decision. He thereupon informed me that he had not quoted the best price, that he could reduce the quotation $300 and still make a profit for himself. Being thus assured, I was given the papers from my file, checked them and found that he was the only man who could furnish the material and the only one who had quoted.

I felt that, having his assurance that his revised price was legitimate and carried a profit, I was not unethical in accepting it. And he never knew that he had bid himself out of $300. This is a concrete example of what you term "lack of price courage."

In the small matter of printing, a few months ago I asked for bids of exact specifications, quoting the weight, watermark, size of paper, style of type and quantity. The seven bids ranged in price from $14.50 to $107 for this lot. I had been accused by this crowd of being a "price hound," and on that basis would have paid $14.50 and gloated at the other fellow's discomfiture when he found out his loss. The high man, I knew, was unreasonable, and so I paid $67, and was assured that the man who furnished the goods was satisfied with the transaction and made a profit.

Still another case: A vender quoted me a certain price. It was one of the strongest buyers' markets that I have ever known, but I quickly realized that he was using me to get the last cent possible without being frank about the situation. In fact, he used many clubs and sticks, took much unfair advantage of our situation, pulled all the wires possible to make me pay a high price on a low steel market and finally, absolutely by his own activities, drove himself to the point where he sold me the equipment for $10,000 less than he originally bid.

In a contract which I am at present negotiating on a large scale for service in our entire territory a nationally known vender with whom I have had many years of well-established contact and from whom I have received very special consideration has in this instance, I now learn, adopted a definite policy of trying subterfuge. The contract submitted carried two or three "jokers," which he acknowledged as having been intentional on his part. He has thus chosen to jeopardize a confidence which we had built up with each other over a period of probably twenty years. What should a purchasing agent do in a case of that kind? There is only one answer.

Still another case: A concern with which, for very special reasons, I desired to place a particular piece of business deliberately added a 3 per cent unnecessary profit. Its representatives talked much and did little, but when—without mentioning the amount which it had added, but with which I was perfectly familiar—I said that we would not pay them the price which they had quoted, they immediately said, "We will take off the 3 per cent."

### What to Do

These are some of the faults perpetuated by venders. Again, however, the purchasing agents are to blame, as I see it, through failure to take advantage of their own opportunities. As an example: For some three years one of my assistants has been experimenting with a certain particular system of order writing. As the work has grown, it was necessary either to find ways and means to reduce the cost of writing orders or put on extra people. He developed a very simple and very economical method, and a few days ago the representative of the manufacturing company told us of this young man's activities and that the results which he had obtained by working so closely with it had opened up for his concern an entirely new field of endeavor. It was a work with purchasing departments which the company had never suspected could exist, and it is going out now to cash in on that. This is simply and solely the result of the work in this purchasing department by a young man who had enough interest to study his job. This vender in showing his appreciation of this kind of co-operation stated that usually the purchasing agent he or his people called on refused to work with them, sent them to many other departments and so lost the value which might have accrued to them and the credit which would come in a constructive piece of work of this kind.

Well, what should be done to help the general situation? I think I have answered this question in the beginning. But to emphasize a bit:

(a) Executives should not give a purchasing agent a title without the responsibility.

(b) The man so selected should exemplify all that is best in business ethics in his association with the sales departments of other companies.

(c) Sales managers should insist that before they contact with a company their salesmen become intimately acquainted with the routine therein. This will eliminate much misunderstanding.

(d) Manufacturers and organizations of purchasing men should co-operate to meet this problem on a constructive basis with a real determination to eliminate the present misunderstanding. It can be done! And I hope to start the work through the auspices of the National Association of Purchasing Agents.

## High-Pressure Pipe Line Fabricated by Electric Welding

A 45-MILE, high-pressure oil pipe line fabricated entirely by electric welding and running from Lamkin to Hodge, La., has recently been completed. The welding was performed under the direction of B. K. Smith of the Big Three Welding & Equipment Company, Houston, Tex.

Oxyacetylene welding was originally applied to such service with excellent results, but estimates indicated that electrically welded joints could be produced at a lower cost. The lowest bid for welding this line by the oxyacetylene method was $2.75 per joint and the bid submitted for electric arc welding was $1.25 per joint. The latter price was considered fair by the Big Three Welding & Equipment Company and in practice proved satisfactory.

The country over which the line runs is rugged and broken. There are hills, deep ravines, woodlands and swamps. There is a river to cross. Despite these physical obstacles the line was laid without difficulty. A total of five gas-engine-driven "Stable-Arc" welders, manufactured by the Lincoln Electric Company, Cleveland, Ohio, were used. In doing the work in the field the welders, of course, operated as a team; that is, four men simultaneously welded four consecutive joints and moved on. The lengths thus formed were joined together by a bell hole operator.

*Portable welding equipment used in pipe line construction and electrically welded pipe line before laying in trench*

The line was built in 5-mile stages, each stage being finished and tested under hydrostatic or gas pressure before further pipe was laid. The joints were all made in two layers, and with this construction, which was developed by Mr. Smith of the welding company, only fourteen pinholes occurred in 11,000 joints.

Shortly after the completion of construction and before the trench was filled a northwesterly storm swept Louisiana and the temperature dropped to six above zero. It had always been the belief of pipe line men that line built during warm weather would break if left exposed to bitter cold of a winter blizzard. In the past, with mechanically fabricated lines, the belief may have been justified, but the new arc-welded line showed no sign of rupture upon exposure to the lowest temperature that Louisiana has known in 30 years.

---

# Benefits of Standard Specifications

Desirability of enlarging N.E.L.A. guides into complete purchase specifications is pointed out. A broader engineering outlook is needed

By James D. Winans
*Public Service Production Company*

SPECIFICATION standardization is one phase of the general subject of standardization which has been receiving a good deal of consideration from the industry and is discussed at every committee meeting in one form or another. Some of the greatest minds of the industry have been concentrated in the last twelvemonth on the selection of suitable voltage ratings. Many of the things that have been said as regards voltage standardization might well have been applied to specification standardization. The formulation of complete purchasing specifications for electrical apparatus and equipment may be classed as the pièce de résistance of standardization.

If one is permitted to put words into the mouths of F. C. Hanker and H. R. Summerhayes, and to imagine what they might have said at the 1927 winter convention of the A.I.E.E., one has only to substitute specification standardization for voltage standardization to obtain the following: "The lack of a logical and co-ordinated standardization of electrical apparatus extending from the initial supply to the utilization devices has resulted in an unnecessary expense to the industry. Specification standardization up to this time has been largely a matter of individual efforts on segregated types of apparatus. There has been a considerable tendency for the users of apparatus to buy equipment of special nature to suit their own particular conditions. Since these conditions would naturally vary somewhat from operator to operator, the special apparatus ordered by them does not constitute a new but unofficial line of standards but a truly special line of apparatus for each operating company.

"Considerable attention has been given to this tendency to deviate from the established standards recognized by the A.I.E.E., N.E.L.A. and N.E.M.A., since although the use of special apparatus might be advantageous from the point of view of the individual operator, it nevertheless places a burden on the industry as a whole, including those purchasers who believe they are being supplied with special apparatus at standard price. Users of standard apparatus help to bear this as well as the users of special apparatus, since the development costs and extra supervision and manufacturing costs caused by the production of specials tend to raise the cost of standard apparatus. The special tools often required for the production of specials also raise the investment in manufacturing plant, and this extra cost is usually borne by the standard as well as the special product. Furthermore, special apparatus entails longer deliveries, both on the initial apparatus and on renewal and repair parts."

R. E. Argersinger in speaking on voltage standardization at the 1927 winter convention of the A.I.E.E. also might well have used the words specification standardization instead of voltage standardization and thus would have said: "Specification standardization is of value to the consumer principally in two ways: First, that equipment may be used under a variety of operating conditions, and, second, that it may be obtained more quickly and at less cost. If the first result can be secured the electrical manufacturer's production problems should be so simplified that the second would follow readily. It should be remembered that in discussing the possibility of securing apparatus at lower prices by standardization comparisons should be based on the cost of equipment actually purchased at present rather than on the cost of the present standard equipment, since it appears that less that half the major equipment purchased is standard.

### Present Standards Not Followed

"The present standards have not been closely followed because, first, the operating companies in general have given too little consideration to simplifying their requirements, and, second, in designing for standardization the manufacturers have placed too much emphasis on cost reduction and have paid too little attention to flexibility of use."

The manufacturers' viewpoint on specification standardization was presented before the electrical apparatus committee of the National Electric Light Association at Pittsburgh on May 3, 1927, by T. J. Pace of the Westinghouse Electric & Manufacturing Company when he said: "If the utility engineers realized what these special orders mean to the manufacturer and the purchaser alike, in the way of cost and delay, compared to an order for something that had been built before and which often would serve the purpose about as well, they surely would be glad to lend their help. It doesn't solve the problem to buy the special thing at the standard price, for that only transfers the burden. The industry, in the final analysis, must assume it just the same. It may surprise you to know that 75 per cent of our orders for power apparatus call for special features of design. It means several million dollars a year, and it would be worth while if it always brought forth improvements. But we feel rather strongly that a good deal of this expense might be saved if the industry would adopt more nearly common standards. What we need is the opportunity to do some manufacturing instead of building so many things to order. Our business at present is too tailor-like, and we all know the difference in cost between a tailor-made garment and a stock garment."

### WORK TO BE DONE

Specification standardization, or any near approach thereto, can be accomplished only by the adoption of standard forms for requests, for quotations and for contracts and by the education of the industry to the point where orders cover equipment manufactured "in accordance with Standard Specification No. A, with the following exceptions," and may these exceptions be the exception and not the rule. J. C. Parker, in the May 29, 1926, issue of the ELECTRICAL WORLD pointed out that it is the essence of any standard that it must be an expression, not of the will of a narrow majority, but of the preponderating thought and feeling of substantially an entire group. Is it not possible for the N.E.L.A., representing, as it does, both the purchaser and the vender, to prepare and sponsor standard specifications that will be acceptable to and adopted by all but the bitter-enders?

It is not to be inferred that every point at issue could easily be settled or that it would be desirable to cover some of these even if agreements could be reached. Examples of the lines along which work might most readily progress are the relation of speeds to capacities of rotating machinery and nameplate data on transformers, voltage regulators, rotating machinery, relays, etc.

Even the field of voltage standardization has not been completely harvested, for not only have the tentative proposals to be more generally accepted, but the tap voltages, which for a great many ratios of transformation cannot be settled merely by the specifying of a percentage within certain limits if satisfactory paralleling is to be obtained, must be prescribed in some such manner as is outlined in the recent article on the power-transformer situation by F. W. Gay and J. D. Winans in the March 12, 1927, issue of the ELECTRICAL WORLD. It has been demonstrated as necessary to tabulate an approved list of secondary turns and corresponding primary full-winding and tap turns for transformers in the so-called power or substation class, and extension of the principle has already been made to transformers for use with synchronous converters.

In considering a piece of apparatus as well established and commonly used as the power transformer, it may be well again, to quote from Mr. Pace, speaking from the manufacturers' viewpoint, when he said: "We furnish somewhat in excess of 2,000 of them a year. We are able to manufacture for stock less than 5 per cent of that number. We cannot escape the endless combination of primary and secondary voltages, the different types, self-cooled, water-cooled, air-blast, etc., not to mention mounting and other requirements for different conditions."

Another important line of product which Mr. Pace used as an illustration is the industrial motor, in the case of which he stated that the Westinghouse company has standardized on 22,000 different machines, but still has its business nearly 50 per cent "special." We cannot blame the manufacturers if they feel a bit disheartened under the circumstances.

It would, it is true, be hard to point out the line of demarcation between such standard specifications and the A.I.E.E. standards. Possibly there should be no difference, the present rules being incorporated in the new specifications, in which case, of course, the duty of preparation and presentation to the A.E.S.C. would devolve upon the A.I.E.E., or at least upon a joint committee of the N.E.L.A. and the A.I.E.E.

L. W. W. Morrow in the May 21, 1927, issue of the ELECTRICAL WORLD pointed out the chaotic conditions existing at the present time in regard to standardization as a result of overlapping jurisdiction and non-co-operative effort on the part of organizations which are as the sands of the sea in number. It would seem better to have the proposed director of standards occupy some such position as executive manager of the American Engineering Standards Committee.

### N.E.L.A. SPECIFICATION GUIDES AS A BASIS

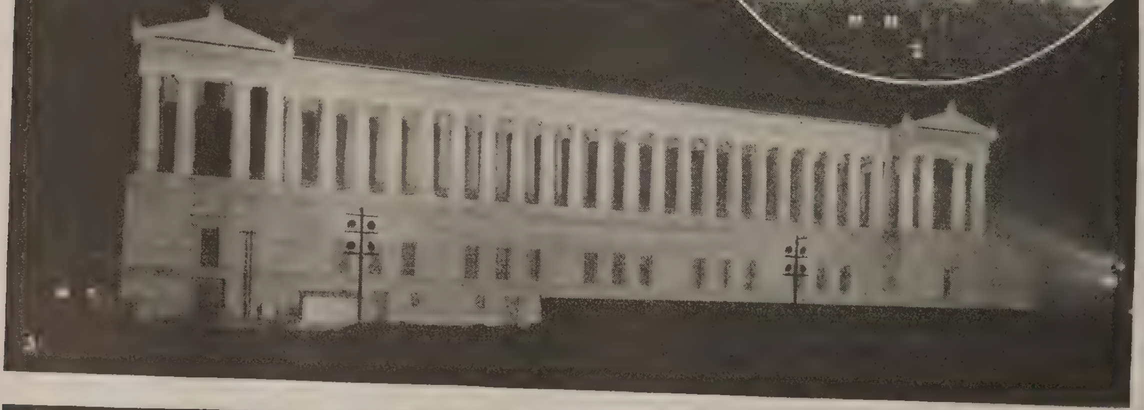
By means of serial reports of the electrical apparatus committee of the N.E.L.A., some sixteen so-called guides for specifications have been presented to the industry in the last year or so, each "intended to serve as a reminder of the points which may be necessary in a specification and as an indication of the logical order in which they should be enumerated." The proposition is then that some group in the electrical industry set out to make a standard, a purchase standard for all apparatus and equipment, by amplifying these guides until they become purchase specifications completely covering, in conjunction with the A.I.E.E. standards, the manufacturing and testing of electrical apparatus and equipment from the viewpoint of the purchaser; not the viewpoint of the purchaser in the narrow sense, as opposed to the best interests of the manufacturers, but in the wider sense, as covering the points in which the purchaser is chiefly interested, and leaving to the manufacturers the greatest flexibility in design in order not to stifle progress.

C. F. Hirshfeld, in an address before the public-utility group of the National Association of Purchasing Agents (see the ELECTRICAL WORLD, Feb. 12, 1927), states that the wise purchasing agent buys most things on specifications of some sort. It is up to the engineer to furnish these specifications, and certain it is that he would have a much easier time justifying his requirements if they were based for the most part on standard purchase specifications recognized by the industry as a whole.

## Large Output in Switzerland

ACCORDING to a report recently presented to the Association Suisse des Electriciens by M. O. Ganguiller, the output of electric generating stations in Switzerland, excluding that from plants having a capacity of less than 1,000 kw., amounted last year to 3,515,000,000 kw.-hr. from run-of-river hydro stations, 439,500,000 kw.-hr. from storage plants and 1,700,000 kw.-hr. from steam stations; 20,500,000 kw.-hr. were "imported" from adjoining countries, giving a total of 3,976,700,000 kw.-hr. This figure does not include the output from state plants serving the Federal Railways.

# *Civic Attractiveness at Night Obtained by Floodlighting*



No. 1. Effective illumination of Soldiers' Monument at Highland Park with two 250-watt units.

No. 2. Wrigley Building, Chicago. Floodlighting has a definite financial value here.

No. 3. Soldiers' Field Colonnade, Chicago. Lighted with twelve 1,000-watt units.

No. 4. Bank building floodlighted with two 500-watt units.

No. 5. An interesting old landmark in Mount Emblem Masonic Cemetery made conspicuous for miles around by use of sixteen 500-watt projectors.

# Fields for Floodlighting

Night illumination of parks, beaches and athletic fields increases their value to public. Floodlighting of private buildings a profitable investment. Fields of application

By A. H. Smith

*Illuminating Engineer Public Service Company of Northern Illinois, Chicago*

SEVERAL years ago when a building in Chicago was first illuminated a humorous-minded newspaper reporter wrote a facetious story in which he estimated the number of sticks of chewing gum represented by the bill for electricity. At that time the nightly expenditure of about $60 for illumination was generally regarded more as a publicity stunt than as a sound business expenditure.

Since that time, however, interest in architectural floodlighting has become so widespread and its development so rapid that today there is hardly a city of importance in the country without examples of floodlighted buildings, and leading architects are incorporating in the design of their buildings special features and adequate provision for the effective use of light as a means of architectural embellishment.

### Floodlighting Lengthens the Day

Moreover, floodlighting is finding an increasing application not only in the lighting of outdoor spaces, such as parks, beaches, athletic fields and other public places, but in the fields of industry as well it is being used to illuminate night work so that 24-hour operation can be carried on with maximum efficiency. Railroad yards, construction work, quarries, docks and outdoor operations such as oil field or refinery work and the like can now be so efficiently floodlighted that hardly any slowing down of work is necessary due to darkness.

For that reason some consideration of the sales factors that influence the use of floodlights and a brief outline of the equipment and methods used in up-to-date installations are of interest to the public utility concerned with supplying the energy for operation.

Floodlight illumination of buildings falls into two general classes—public buildings or monuments and private structures. The chief factor governing the use of light on public monuments and buildings is, of course, civic pride. The use of abundant light in making a public place or monument attractive is just as effective when it is used to draw crowds to a civic community house as it is when used to draw crowds to a theater. People at night time instinctively tend to congregate in a brightly lighted spot, and the brilliant illumination of a public building or monument is one of the simplest and most logical means of increasing its effectiveness and extending its usefulness. With modern methods of city planning and the recognized importance of focusing the city's life around certain definite civic centers, the use of floodlighting becomes one of the most certain and most economical methods of drawing the community's life to the desired points.

In the floodlighting of areas other than buildings the same reasons that lead to the use of floodlights on buildings and monuments are applicable to public parks, beaches, playgrounds, athletic fields, etc.—namely, civic pride and increased usefulness. There is little doubt that the factory worker and the city dweller in general favor daylight saving time schemes because they permit an extension of recreational activities into the hours after work. Floodlighting public recreational facilities serves exactly this same end and accomplishes it without the annoyance of manipulation of the clock.

*Standard tower for mounting floodlighting projectors*

When a community properly illuminates its bathing beaches, its athletic fields or its playgrounds, the result is the same in a way as opening up additional beaches or building increased playground facilities. There is perhaps no cheaper and easier way of quickly providing increased recreational facilities than by this means. Attendance figures in instances where public recreational facilities have been adequately illuminated show that a comparatively small expenditure of this kind will make these facilities available to thousands of persons who might otherwise seldom be able to use them. When the total amount of money involved in the construction and the maintenance of public parks and playgrounds is taken into consideration, the expenditure required for adequate illumination is a comparatively trifling sum. And getting the maximum use out of a plant or an investment is just as sound business in the case of a public institution as it is in the case of a private one.

In addition to the fact that floodlighting increases the usefulness of public facilities, one of the prime considerations is the added safety that proper illumination assures. This is particularly true of bathing beaches, and the safety factor is of almost equal importance in any large open space where people congregate in large numbers. The value of good illumination as an aid to adequate police surveillance is, of course, too obvious to need pointing out.

*One bank of thirty 1,000-watt projectors on the Wrigley Building, Chicago*

Nowadays a municipal stadium is certainly not complete without adequate provision for night illumination. One outstanding example of the increased effectiveness of a stadium made possible by night lighting is that of the Soldiers and Sailors Field at Chicago. During the outdoor season this great public institution is almost as effectively operated after dark as during the daylight hours. Recognizing the necessity of night lighting from the start, the design of the field was planned with this idea in mind and provisions were made for an effective floodlight installation. Properly designed platforms and columns that support the necessary floodlight projectors are an architectural part of the structure itself.

The result is that large religious gatherings such as the great Eucharistic Congress of 1926 and events such as the Chicago Rodeo, etc., are as effectively held after sundown as by the light of day. Although the Chicago installation is a large one involving the use of approximately a hundred 1,000-watt projectors, the cost of its installation and operation is insignificant compared with the public benefits derived.

In the field of private institutions, efficient floodlighting of a building can in many cases have a definite financial value. It may not have been anticipated in the case of the Wrigley Building that the nightly illumination would be of value in keeping rental space filled with tenants. And yet that was one of the most striking results.

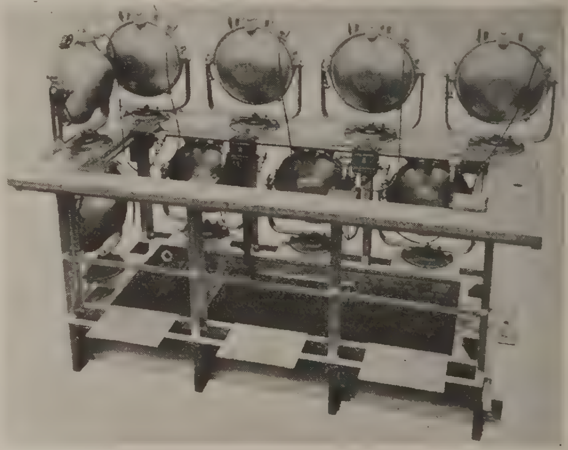
A recent article in *Building Investment and Maintenance,* devoted to the interests of building management, says:

"One of the principal things being sold by the owners of office building space, whether the building is occupied principally by one company or whether it is divided up among a large number of individual tenants, is a well-known address. Tenants buy this feature of established location, and particularly in the case of a new building is it necessary to get the building known quickly. No other method does this job so quickly and so satisfactorily as floodlighting of a building where there are any striking features worthy of the lighting. The cost of the floodlighting comes back in quicker rental, sometimes in a higher rental scale, and certainly in satisfaction to the tenants."

Another effective use of floodlighting is found in the increasing practice of real estate companies and builders of illuminating newly constructed homes as a means of advertising them. Although the temporary nature of installations of this kind does not make it particularly desirable business for a public utility, it has been found that such installations are an effective means of stimulating interest in the possibilities of floodlighting and frequently pave the way for large permanent installations for other uses.

The industrial uses of floodlighting over large outdoor areas cover an extraordinarily wide range. The use of floodlights to enable construction operation to continue at night is having an increasingly wide application. The value of adequate light in speeding up any kind of work is none the less effective because a workman is employed outdoors rather than at a bench. In addition, the insurance value of adequate general lighting in the prevention of theft and tampering where machinery and material must be left outdoors is an important item.

Although floodlight installations on construction work may be of minor interest to the public utility, due to their temporary nature, the value of other industrial uses is easily recognizable. There are few factory establishments with extensive open storage yards that are not legitimate prospects for floodlighting installations. The value of such lighting equipment where the factory is likely to be operated at night is obvious. Driveways, loading platforms, storage piles and the like are perhaps more effectively lighted by this method than by any other. Particularly in the case of lumber yards, coal yards and similar areas where the theft of material is a constant hazard the use of floodlights is one of the most effective means of prevention.



*Tower basket with capacity for eighteen projectors*

It is designed for permanence with a view to easy maintenance and safety. Conduit is an integral part of the basket and entrance is through a trapdoor in the floor.

Some of the most important installations of floodlights for the illumination of extremely large areas is to be found in the recently adopted practice of several railroads to illuminate their switching and storage yards by this method. Since switching operations must be carried on at night as well as by day and since a railroad yard usually represents a sizable piece of property, the illumination of these large areas has been until recently extremely difficult. It is constantly necessary for switchmen to be able to recognize the numbers and designations of freight cars while they are in motion, and carefully planned floodlighting has made this possible in every instance. As might be expected, the job of a switchman in a dark yard filled with moving trains is a highly hazardous occupation, hence floodlighting is an important advance from the standpoint of safety. One of the notable recent installations of this kind is that which was made in the Wabash Railroad's classification yards in Chicago.

Since the development of floodlighting has taken place only within the past few years and since the best equipment is nearly all of comparatively recent design a brief review of the general principles involved and a description of the most successful types of equipment are important. Primarily the development of the high-wattage Mazda lamp has made possible present-day development of floodlighting projectors. These lamps have supplied the illuminating engineer with a source of light of great volume and high efficiency that can be operated effectively throughout the life of the lamp. Using these lamps as a basis, it has been the attempt of the illuminating engineer and far-sighted manufacturers to develop projectors that afforded maximum projection for the light flux emitted.

*Construction work at night made possible and safe through floodlighting*

Although illumination can be obtained by simply disposing high-powered light sources at various points and equipping them with the conventional type of open reflectors, the results obtained by this method cannot compare either in brightness or in efficiency, much less in installation cost, with a method that assures maximum control of the light by placing the lamp in a scientifically designed projector, which projects the greater portion of the light rays into a single beam and, by the use of properly designed optical lenses, diffuses and focuses the rays effectively over the area to be illuminated.

For example, a Chicago advertising company recently desired to illuminate a large sign covering almost the entire side of a fifteen-story building on Michigan Avenue, and extreme brightness was desired. The preliminary estimates involving a certain type of projector indicated that approximately 4.5 watts per square foot would be required. Upon a revision of the estimate, however, by an illuminating engineer, it was found that by the use of eight 1,000-watt projectors equipped with rectangular divergence lenses that would refract the rays of light and distribute the illumination evenly over the entire area it was possible to get an even brighter illumination than had been contemplated with only a little more than 1 watt per square foot. It is evident that the use of properly designed equipment improves results and minimizes current costs, thereby increasing greatly the number of available prospects by getting current requirements down within reason.

The application of properly designed reflectors equipped with carefully designed optical lenses for control of the beam makes possible the illumination of comparatively large areas with a very small number of units of high wattage. As a general rule it has been found that a smaller number of large projectors of great capacity give much more satisfactory results than a large number of smaller units. Certainly it simplifies the problem of installation and maintenance and at the same time permits the illumination of many areas that could not be lighted with small units except at prohibitive expense.

The economical use of units of high capacity may be said to have been made possible by the development of suitable lenses so that adequate control could be had over the distribution of light. The parabolic reflector with which the projector is equipped serves to concentrate the light, but has the disadvantage of projecting simply an image of the filament. Where the beam is to be thrown across long distances and concentrated as much as possible within a small area, there is sufficient diffusion of the filament image so that a lens is not needed and the best results follow the use of a clear cover glass made for the door of the projector.

However, in case the projector is intended to illuminate larger areas or areas of rectangular shape, other means must be provided for diffusing and distributing the light over the desired area without too great loss of efficiency. As a means of getting efficient distribution and an even spread of light the best practice now is to use suitable lenses in the door of the projector. The simplest form is a door of stippled glass, which scatters the light. The efficiency of this sort of diffusion is very low, however, and has resulted in the development of optically correct lenses that gather the light, confine it entirely to the desired area and effect a perfectly uniform distribution without filament images or streaks. A complete range of such lenses has been developed and their proper use enables some distinct economies in the amount of light needed and at the same time assures perfectly even distribution.

A so-called rectangular diffusion lens has been developed that projects a rectangular-shaped beam in which all the light is concentrated and which cuts off sharply at the edges so that none is wasted and so that one beam may be placed alongside another without streaks and dark patches where they overlap. Other types of lenses effect what is called circular diffusion over a 45 deg. arc and replace the wasteful stippled glass door where a broad area is to be illuminated close at hand by one or more high-power projectors.

The earlier types of projectors for the most part made use of silvered-metal reflectors similar to those used in automobile headlights. The superior efficiency of the silvered-glass reflector, however, has led to its adoption in the better designs, the best practice being to place the silvering on the side of the reflector away from the lamp.

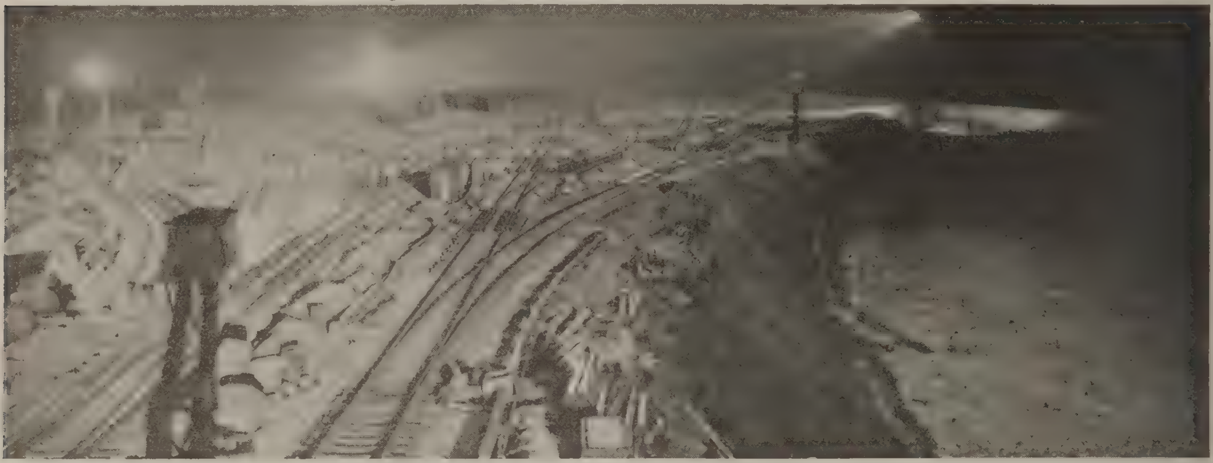
The earlier types of large-capacity projectors were practically all of the ventilating type. That is, in order to carry away the considerable amount of lamp heat it was necessary to circulate air through the lamp for ventilation. This practice had the disadvantage that dust and smoke were deposited on the inside of the lamp so that the efficiency of the projector was soon impaired by dirty reflectors and lamps, making frequent cleaning necessary.

Severe corrosion of the heated metal parts was likely to be set up by the circulating air and breakage of lamps and reflectors was excessive due to the fact that particles or even drops of water were often carried into the projector by the air stream and deposited on the heated lamp or reflector. It became necessary to evolve a non-ventilating type of projector so designed that the heat of the lamp was carried away by radiation rather than by direct ventilation.

Some manufacturers are now producing non-ventilating projectors that are entirely airtight, thus keeping all smoke, dirt and moisture out of the inside of the projector and eliminating all necessity for maintenance or opening except for lamp renewal. Practically the only maintenance necessary on good equipment now is a periodical washing of the outside face of the projector in order to remove the smoke and dirt deposit.

Another point of importance is the construction of projectors from materials that will not corrode due to the action of smoke and gases. This is particularly true in the cases of installations in railroad yards and industrial districts. The use of bronze and aluminum throughout is the best sort of economy.

Projectors are also fitted with suitable focusing devices and with mountings that permit a permanent setting of the direction in which the projector is pointed and yet permit it to be released so that it can be turned into convenient position for cleaning and then returned to the same fixed, permanent adjustment.



*Night view of Wabash classification yards, Chicago*

When the projector is intended for the illumination of ground surfaces, it is well to place it as high above the ground as practical, on buildings, water tanks or steel towers that have been developed for this special purpose in a standardized form that reduces the cost considerably.

When the projector is used for illumination of signs or wall areas, it should be placed below the eye level if possible or at such an angle that the angular reflection of the beam is not directly at the observer.

The methods of disposing projectors for the illumination of large areas such as railroad and factory yards, quarries, storeyards, etc., is well illustrated in the recently installed floodlight system used for the Wabash Railroad classification yards at Chicago. Lighting this yard, which is almost a mile in length, involved the lighting of an area of more than one and a quarter million square feet of tracks, one-third of which comprised the ladder tracks, requiring an illumination to the intensity of 0.145 lumen per square foot, whereas the remaining two-thirds, comprising storage tracks, called for an intensity of 0.073 lumen per square foot. This was accomplished by the use of fourteen standard 1,000-watt projectors, which were divided among three 100-ft. standardized floodlighting towers. Where beams of wide divergence were required to illuminate the areas close to the towers, the projectors were fitted with 45 deg. circular divergence lenses; on the longer throws clear lenses of heat-resisting glass were used. One tower was located approximately at each end of the yard and the third tower was placed in the center of the yard so that the projectors cast light in both directions.

The towers used in the Wabash yards are of a standardized design evolved especially for floodlighting work by the engineers of the American Bridge Company and the Pyle-National floodlighting engineers. The towers are completely fitted with integral electrical fittings, and it is interesting to note that they are assembled on the ground on this particular installation and raised into position in less than ten minutes, the entire installation of the floodlighting system being installed in a few days' time.

## Electricity Consumption on the Farm

By Frank D. Paine

*Supervisor Iowa Project on Rural Electrification, Garner, Iowa*

FROM records of the rural electrification project at Garner, Iowa, there is presented here an analysis of the consumption of electricity for various uses on a dairy farm of 195 acres. In the home there were used in one year 816 kw.-hr., according to the tabulation:

| | Kilowatt-Hours | | Kilowatt-Hours |
|---|---|---|---|
| Lights | 360 | Water supply | 245 |
| Washing machine | 65 | Radio | 100 |
| Iron | 40 | Vacuum sweeper | 6 |

The above uses are listed in the order of their preference by the wife of the farmer. She would like to add to the list a refrigerator and an ironer, which would use 550 kw.-hr. and 72 kw.-hr., respectively.

The consumptions in the farmstead were as follows:

| | Kilowatt-Hours |
|---|---|
| Building lights | 120 |
| Milking machine (24 cows) | 540 |
| Separator | 54 |

These farm uses of electricity are not extensive. Grinding oats and barley would easily add 320 kw.-hr. Ensilage cutting, corn grinding and grain elevating could be done electrically, too.

The actual use of electricity on this farm in one year was 1,548 kw.-hr. To get a complete idea of how much energy this farm might easily use, there must be added to this figure the consumptions of the refrigerator, ironer and feed grinder that are next on the list for purchase. This makes the annual consumption rise to 2,472 kw.-hr.

Another case—a stock farm of 320 acres. Actual consumption was:

| In the Home: | Kilowatt-Hours Per Year | On the Farm: | Kilowatt-Hours Per Year |
|---|---|---|---|
| Lights | 372 | Building lights | 120 |
| Water supply (for both hard and soft water) | 49 | Milking machine | 212 |
| Washing machine | 22 | Separator | 38 |
| Iron | 38 | Elevating grain (7,000 bu.) | 64 |
| Refrigerator | 365 | Corn shelling (1,000 bu.) | 40 |
| Radio with battery charger | 64 | Sawing wood | 20 |
| | | Incubator | 300 |
| | | Feed grinding | 400 |

## Business Allocation at Cambridge, Mass.

AN INTERESTING exhibit of the Cambridge Electric Light Company in the recent rate case before the Massachusetts Department of Public Utilities presented the ratios of different classes of business handled by the company in 1926 to total business, as given in the accompanying table. This company serves a diversified industrial and residential community with a population of about 150,000 (including Belmont, which is supplied at wholesale). Its gross electric revenue in 1926 was $2,024,377, its total operating expenses $1,367,835 and the present value of its property on the reproduction cost basis was computed at $8,035,469. The total sales of energy were 53,675,929 kw.-hr., of which 14,115,232 kw.-hr. was for metered lighting, 34,576,077 kw.-hr. for power, 1,823,183 kw.-hr. for municipal arc and incandescent lighting, 260,262 kw.-hr. domestic power sales and 2,901,175 kw.-hr. sales to other companies.

CLASS CHARACTERISTICS IN PER CENT OF TOTAL 1926 BUSINESS
CAMBRIDGE ELECTRIC LIGHT COMPANY

| | | | —No. of Customers— | |
|---|---|---|---|---|
| Class | Demand Responsibility | Kw.-Hr. at Buses | Average During Year | Average End of Year |
| Residence lighting | 23.25 | 12.32 | 79.94 | 80.40 |
| Commercial lighting | 18.37 | 12.36 | 14.33 | 13.75 |
| Refrigeration and cooking | 0.87 | 0.73 | 1.48 | 1.82 |
| Primary lighting | 10.39 | 7.27 | 0.01 | 0.01 |
| Power | 44.72 | 64.09 | 4.24 | 4.02 |
| Street lighting | 2.40 | 3.23 | ...... | ..... |
| Totals | 100.00 | 100.00 | 100.00 | 100.00 |

It is seen that while the kilowatt-hours for lighting are about equally divided between residential and commercial, the demand responsibility of the former is more than one-fourth (26 per cent) greater than that of the latter, in itself justifying a higher unit price for residential use, since the delivery of 1 kw.-hr. ties up more equipment. Further, less than half the demand responsibility falls on the power load (44.72 per cent), while nearly two-thirds of the output goes to it. Here again the proportionate share of plant is much smaller than the proportionate share of load.

Returns also show a much smaller relative demand responsibility, and therefore a smaller proportionate share of investment per kilowatt-hour for refrigeration and cooking than for lighting, definitely justifying a separate and much reduced rate for refrigeration and ranges, though it should, from the data, average higher than the rate for big power.

## Electric Pumping Service for Oil Pipe Line

AN OIL pipe line about 400 miles long from the West Texas fields to Cushing, Okla., is now being laid by the Shell Pipe Line Company, according to a paper presented at the Oklahoma Utilities Association convention by O. A. Jennings. The line, of 10-in. pipe, will contain fourteen pumping stations, all electrically driven and supplied with energy from the systems of the Oklahoma Gas & Electric Company, the Southwestern Light & Power Company, the Texas Power & Light Company and the West Texas Utility Company. Each station will contain three 400-hp., 2,200-volt motors direct connected to centrifugal pumps. Two units in each station will be in normal operation, the third being held for stand-by. The annual load factor of this business will be about 90 per cent according to preliminary estimates and surveys of operating factors for such service.

This installation will be one of the first completely electrified pipe lines in the country. The decision of the Shell Pipe Line Company to use electric drive throughout was made after careful comparison of electricity with other forms of power. The principal virtue of the use of electric power is the lower initial cost, about one-third less than steam or oil. The need for only one attendant per station reduces labor charges. Repairs, maintenance and depreciation are much less. Centrifugal pumps, which on account of their high operating speeds are best driven by electric motors, possess peculiar advantages over reciprocating pumps for pipe lines. If the line becomes plugged the pressure will not exceed a predetermined definite amount, which may be provided for in the design of the line. If any pump stops it does not constitute a complete obstruction because the oil, under pressure from the other pumps, can continue to flow through it. These considerations, and others, decided the Shell Pipe Line Company to go to all-electric operation of the new line.

# Letters from Our Readers

## *Economical Installation of Wiring*

*To the Editor of the* Electrical World:

The subject of more economical wiring installations has had considerable discussion by the N.E.L.A. wiring section and jointly with other associations. It appears to lead to one conclusion, namely, that a more suitable design of conductor is desired. This thought has brought about a number of methods and materials which their advocates claim substantially reduce the expense of installing wires. Today we have advocates for concentric conductors, non-metallic sheathed cable with all wires insulated and also with one wire bare, and flexible steel conduit with one bare wire and those that demand both wires insulated, as in the past. Also the old favorite knob and tube method, which will always have many advocates. It is a fair question to ask if any of these methods, made into a standard, will relieve the cost of installing wiring or of making extensions to a sufficient degree to warrant all this effort, with also the possibility of some new material being designed to replace all or some of the existing materials?

Another item of considerable moment, which also pertains or rather is related to this subject, is the automatic protection of circuits. Favorable action will no doubt be taken soon on some design adaptable for recognition and inclusion in the code. The present activities concentrate on branch circuits, but this should be carried through to as large capacities as the type will permit. Such acceptance will give advantages to the entire industry and offer many economies that will be difficult to obtain through any other medium.

Regardless of the style of wires, we are compelled to utilize two, and very little is to be gained by reducing the quality of the insulation, considering the possible hazard involved. It might be policy to permit the grounding or solid wire to remain in its present insulated condition and place a better quality of covering on the outside wire and allow these to be run under the present rules for non-metallic cable. This has the advantage of allowing the installation of switches without requiring a loop system. This system has some advantages, but they are more than offset by the additional cost.

Many central-station companies, to combat the evil of overfusing and bridging of circuits, have required that the main service fuses be sealed. Several of these concerns have stated that with the acceptance of a type of fuse and cutout or other means to prevent this abuse they will gladly discontinue sealing the main fuses, thereby eliminating one type of equipment that is causing a large amount of the present-day expense of installing wires, namely, the carrying of many duplicate styles of merchandise for the same purpose. Some few years ago we had the condition of 37 or 38 attachment plugs and out of the confusion a satisfactory standard was adopted with benefit to all concerned. The situation is similar to the practice in vogue on safety switches. One jobber carries fifteen different types, while any one of them would answer the need for a proper disconnect means. Such circumstances should be corrected before a great deal of stress is placed upon the necessity for a more economical conductor.

Another feature for reducing the cost of construction in this class of building would be for some organization to group together all the possible tools and a list of the manufacturers and try to improve or redesign, with the view of providing a quicker method to facilitate the workmen in their problems, and more particularly relating to finished house extensions. The field offers an opportunity for the inventive minds of the artisan as well as the executive. Some action to promote interest in such a proceeding should bring about improvements of a decided nature. Anything that can reduce the labor expense will offer greater possibilities than a small reduction in material costs of conductors. Without question this would increase consumption through the added convenience of installing additional outlets. The labor item on this class of buildings is considerably in excess of material costs. The experience of all trades in reducing the labor required for a given task is satisfactory proof that a larger amount of business can be expected through any effort of a concerted nature to lower this item.

The rule calling for twelve outlets on a circuit may now be omitted, under certain conditions. This has probable advantages, but it should not be encouraged until such a time as the rules recognize a type of fuse that cannot be overfused or easily bridged. When this condition arrives—and it should at an early date—the requirements for twelve outlets on a branch circuit can be dropped from the code, and allow, perhaps, any number of outlets, as circumstances warrant, with a possible floor-area limitation. Such a condition appears to the minds of many as the ideal arrangement and would constitute one of the most economical means for reducing the outlay for new work and extensions in old buildings.

If the various interested organizations would combine and employ a field secretary and instruct him to tabulate all such information and work in conjunction with any cause along these lines a probable benefit would accrue to every branch of the industry. A great deal of improvement could be accomplished through such proceedings to the welfare and betterment of the fraternity.

C. W. Cowles.

# Digest of Electrical Literature

## *Hydro-Electric Development and Steam Equipment*

*Pulverized Fuel at Derby.* — The results of the first eight months of operation of a pulverized fuel plant at the Derbyshire Corporation station are summarized in this article. The equipment used is outlined and the economies and operating conditions involved are offered for average conditions. The mills are of the Raymond type and pulverization is effected by rollers running in contact with a steel ring.—*Electricity (England)*, March 15, 1928.

*Electricity and Fuel Conservation.*—W. T. Townend.—The economic considerations involved in the generation of electricity and the combustion of coal have been reviewed by the author with particular reference to the generation of electrical energy in plants producing coke, and at mine-mouth operations. The discussion refers particularly to the possibilities in Great Britain and because of the local factors involved is particularly applicable to that country.—*Electrical Review (England)*, March 30, 1928.

## *Transmission, Substations and Distribution*

*Load-Ratio Control Transformers.*—M. Cornudet. — Transformers with voltage taps, and an electro-mechanical arrangement for the change of these taps without load interruption, will, according to the author, give an apparatus which is less expensive than an induction voltage regulator or a synchronous converter. They are, in addition, applicable to high voltages, while the regulator and the converter cannot be built safely for more than 6,600 volts. A Swedish concern has developed such a transformer tap-switching arrangement or load-ratio control for voltages up to 77 kv. and 350 amp. The apparatus is built in three types, suitable for 10,000, 33,000 and 77,000 volts, but the basic principle is essentially the same for all. When changing from one tap to the next the step is first prepared by closing an auxiliary contactor, which establishes a current by-pass over an ohmic resistance, then the main tap contact is moved to the next position, whereupon the by-pass is opened again. Since the whole cycle takes but two seconds the load current flows through the resistor only for a very short period. During this transient period, when stopping of the mechanism would burn out the resistor, a warning signal is given. A three-phase transformer with five regulating positions requires seven contactors per phase, or a total of 21 switches, which are mounted in three switch tanks, suitable for outdoor use. A great number of transformer connection diagrams are given, to show the use of such equipment for various applications, such as power transformation, regulating transformers and tie-in transformers.—*Bulletin de la Société Française des Electriciens,* Vol. 77, 1928.

*Systematically Sectionalizing Primary Circuits.*—Vernon W. Palen. — The practices developed as a result of many years' experience with the sectionalizing of primary circuits is offered by the author in this exposition of suggested procedures. The discussion centers largely around operating and test methods of particular interest to operating men. It is stated that in sectionalizing primary circuits to lessen trouble and restore service to all consumers at the earliest possible moment one company has found it advisable to avoid manipulation of potheads whenever possible and to arrange sectionalizing so as to restore the service furnished to consumers who, due to size of establishment or nature of work, will be the most handicapped by a prolonged shutdown. On single-feed circuits it is suggested that the tests be carried out after underground cable is tested from the end of the primary nearest the substation, picking up the load of each tested section from the outside primary coil. On single-loop circuits with the open loop at the center the procedure for testing from the center of the loop to substation, taking up load at each testing section, is advocated. On double-loop circuits a similar procedure is advised, since each individual loop of a double-loop circuit has its own circuit breakers and disconnecting switches, and, therefore, is held to be independent and may be treated as a single loop. — *Electrical Times (Australia)*, Feb. 27, 1928.

## *Generation, Control, Switching and Protection*

*The Static Balancing of Rotors.*—B. P. Haigh.—The balancing of rotors for electric machines involves, according to the author, two fundamental methods, the theoretical and the practical. While the theoretical principles have long been firmly established on the basis of Newton's laws of motion and probably no longer admit of any important development, the practical art of balancing is said to change from year to year and to vary according to the character of the rotor and the requirements of the circumstances under which it will be used. The various conditions of unbalance, that is, static, dynamic, internal and their combinations, are discussed by the author in connection with mathematical expressions for the significant factors. The subject of the critical speed has received particular attention in this first of several articles. The ratio between the two critical speeds, the secondary or dynamic and primary or static, has been expressed in connection with this consideration.—*Engineer (England)*, March 23, 1928.

## *Units, Measurements and Instruments*

*The Thermal and Electrical Conductivity of Some Aluminum Alloys and Bronzes.*—Ezer Griffiths and F. H. Schofield.—The primary object of the investigation undertaken by the authors was to obtain approximate values for the thermal conductivities of alloys employed in the construction of aero-engines. The measurement of the electrical conductivity of the alloys was undertaken to throw light upon its relation to the thermal conductivity. For this purpose an accuracy of 1 per cent was assumed to be sufficient. The method used consisted in a comparison of the drop of potential across a measured length of the specimen with that across a standard resistance arranged in series with it, when a steady current of the order of 20 amp. was passed through the two. Two thermocouples of copper-constantan were pegged into the specimen, serving not only to measure the temperature but as potential leads for resistance measurement. By appropriate switch arrangements the thermocouple wires were arranged to be rapidly altered so as to serve either purpose as required. As any temperature difference between the two ends of the bar would give rise to a thermal electromotive force, when measuring the potential difference across the bar, readings of the latter were obtained for the two directions of the current, so that by taking the mean of these values the effect of the thermal electromotive force was eliminated. In determining the resistivity the usual procedure was to take measurements on a series of rising temperatures and to repeat the process until a steady state had been reached.—*Engineering (England)*, March 9, 1928.

## *Illumination*

*A New Art in Electric Lighting.*—W. E. Bush.—The comparatively recent development of the use in lighting practice of sheet glass fixtures—that is, fixtures concealed behind glass panels—and of other modern innovations in the lighting art are reviewed by the author. It is stated that one feature of the new lighting practices is the tendency, and in some cases the necessity, for planning by the architects to co-ordinate the scheme and the details of installation with the design of the building. This is particularly the case when glass panels must be installed flush with the walls, ceiling columns, etc. It is anticipated that such equipment will become one of the major features of importance in the design of homes and other buildings of the future. A factor in the new lighting which commends itself to illuminating engineers is the possibility of obtaining a high intensity of illumination with a low surface brightness of the lighting equipment. This is due to the much greater area of glass that is used than if ordinary fittings were employed and, secondly, it is generally necessary to use a number of the medium-sized lamps instead of a smaller number of large lamps. In either case, however, it is neccessary that a liberal allowance be made for a total wattage if pleasing results are to be obtained. The need for investigation by illuminating engineers upon this subject in order that a high degree of efficiency may be made possible by the use of reflectors and careful selection of a glass which combines good light diffusion with low absorption is pointed out.—*Electrician* (*England*), March 30, 1928.

## *Motors and Control*

*The "Electromersible" Pump.* — A specially designed centrifugal pump driven by an electric motor has recently been developed as a single unit. The machine consists of a three-phase squirrel-cage motor combined with a centrifugal pump the rotor of which runs in the water. The stator core and the windings are protected with a watertight, non-corroding inclosure which is filled with transformer oil. The oil forms a good cooling medium and also prevents condensation of the atmospheric moisture in the winding inclosure. In this device the water enters the suction at one end of the motor and passes through an annular space in the rotor which is joined to the impeller. The shaft therefore runs freely between the two end bearings without requiring any glands and the leakage water around the periphery of the impeller fills up the space around the stator winding inclosure and is drawn into the suction again at the running clearance of the rotor at the opposite end, thereby forming a very efficient cooling circulation when the motor is working above water. The oil- and water-tight inclosure is of a special alloy and is entirely stationary. Such devices have been manufactured for an output of 100 tons per hour against a 75-ft. head and are said to operate equally well above water as when submerged under 40 ft.—*Electrical Review* (*England*), March 30, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*Electrolysis and Its Mitigation.* — W. B. Buchanan.—The author has reviewed the general problems involved in the prevention of electrolytic destruction of water pipes and other metallic conductors located under ground, has analyzed the effects of stray currents and of electrolysis conditions and offers a survey procedure for the elimination of the difficulties. The necessity for good conductivity in the joints of pipe lines is particularly emphasized, as it is stated that if the potential drop across the joint due to the flow of stray direct current is a fraction of a volt, part of this current will be shunted by the soil which is in contact with the adjacent ends of the two pipes. The amount of current, of course, depends on the electrical resistance of the soil as well as the difference in potential, but any tendency whatever in shunting of current in this manner is hazardous and should be avoided. The meters and measurements which may be utilized in analyzing the conditions covering electrolysis are mentioned as important, even though great precision in the measurement of current is not attainable. — *Electrical News* (*Canada*), March 15, 1928.

## *Heat Applications and Material Handling*

*Resistance Welding Machines.*—A. Hilpert.—During the last ten years metal industries have adopted electric resistance welding to a wide extent, since the joining of straight or round pieces to produce either a mechanical or a tight connection can be accomplished more quickly and cheaply than by riveting or folding. This article gives an extensive description of modern welding machines of European manufacture, covering butt-welders, spot-welders, seam-spot welders, continuous seam welders, rivet heaters and electric forges. Depending upon the cross-sections to be joined, butt-welders have a hand-operated, motor-driven or hydraulic compressing device. Spot-welders are frequently combined with a current-limiting device to prevent excess current demand and overheating. Seam welders are found useful for steel up to $\frac{5}{16}$ in. thickness. An interesting example of a double seam welder is shown for steel barrels, joining both heads simultaneously. All of these machines have transformers with adjustable winding ratio to accommodate the secondary current to the thickness of the welded piece. The present tendency of rivet heaters is toward air cooling, to avoid inconveniences and the possibility of freezing attendant upon water cooling.—*Zeitschrift des Vereines Deutscher Ingenieure,* March 3, 1928.

## *Traction*

*Suburban Railway Electrification.*—A description of the equipment and design of the suburban section of the Bombay, Baroda and Central India Railway. It is stated that as railway services under steam operating conditions proved unequal to the task of transporting the rapidly increasing number of suburban residents on the line, electrification was planned and carried out. Among the interesting features of this equipment are: Trains consist of unit equipment—that is, driving trailer coach, motor coach; the control equipments are capable of operating three four-coach units—that is a twelve-coach train accommodating 1,500 passengers; the capacity of the existing steam trains being about half this amount, a fully loaded train may be rapidly accelerated and it is possible to attain a speed of 27 m.p.h. within 30 seconds from the initial start; unusual conditions of heavy floods, often causing 2 ft. or more of water on the rails, requires the specification of watertight equipment. Operating factors and economies are considered.—*Electrician (England)*, March 23, 1928.

## *Telegraphy, Telephony, Radio and Signals*

*Long-Distance Radio Receiving Measurements.* — Tomozo Nakai. — It is stated that measurements on radio wave intensity of the order of thousands of microvolts may be made by comparatively simple devices and arrangement, but that to measure quantitatively and accurately such a weak radio field intensity as is of the order of tens or units of microvolts per meter it is necessary to make use of a particular arrangement to which the greatest care should be paid in design, construction and calibration work, otherwise the errors of the measurement may be large. As a result of a scientific and technical investigation of the received radio wave intensity allowing for diurnal and seasonal variations the author undertook the construction of the receiving set unit and local signal oscillator unit with proper shielding devices and in the first discussion has detailed the methods of measurement, arrangement, calibration, accuracy and similar factors of importance.—*No. 217, Researches of the Electrotechnical Laboratory, Japan.*

## *Miscellaneous*

*French Tidal Power Schemes.*—The construction of tidal power stations forms part of a national scheme which is being carried out in France for the utilization of all available sources of energy with the object of rendering that country as far as possible independent of foreign coal supplies. Plans for tidal power installations along the coast of Brittany and the Channel have already been prepared representing a total of something more than 2,000,000 hp. The scheme receiving greatest consideration in this discussion is that of Defour, which utilizes the relative levels of two basins. In the Defour system the auxiliary basin, which only drives the turbines on a discharge into the sea, takes over the work when the head from the principal basin falls too low. There is thus a fairly regular output during the whole period of the rising and falling tides. This does not provide for peak loads and the problem would seem to be complicated by the tide advancing one hour in twenty-four hours. This makes it difficult to insure a concordance between the energy produced and the load curve. So far as theoretical considerations go, it is stated that the schemes are proving attractive to big electrical and mechanical engineering corporations.—*Engineer* (*England*), March 23, 1928.

# News of the Industry

## Boulder Dam Feasibility in Doubt, Says A.E.C.

### *Committee of Eminent Engineers Finds Unanimously that Colorado River Development Should Be the Subject of Further Expert Investigation*

A SPECIALLY appointed committee has just reported to the American Engineering Council against the acceptance of existing reports as evidence of the engineering feasibility of the Boulder Canyon Dam on the California River which the Swing-Johnson bill, now before Congress, would make it incumbent upon the federal government to build.

The personnel of this committee is of a nature to make its finding carry great weight in the engineering world. The chairman, Francis Lee Stuart, has been chief engineer of both the Erie and the Baltimore & Ohio Railroad and has had part in much important work involving hydraulic construction. In the last few years he has been a consultant in connection with the greater harbor project of Los Angeles, the lake-lowering controversy as it affects Chicago, the regulation of the great lakes, lake-to-gulf transportation and the "giant power" plan of Governor Pinchot. The four other members of the committee are Allen Hazen of New York, an expert on water supply; Clemens Herschel, a former president of the American Society of Civil Engineers and the inventor of the Venturi water meter; J. Waldo Smith, who was chief engineer for the New York Board of Water Supply from 1905 to 1922 and completed the new Croton Dam for that city, and Lewis B. Stillwell, former president of the A.I.E.E. and an outstanding electrical engineer, who has just been elected for the fourth time as chairman of the Engineering Foundation.

The committee's report follows:

> The undersigned, constituting the committee appointed by the American Engineering Council to examine the Boulder Dam project from an engineering standpoint and advise the council in regard thereto, respectfully report as follows:
>
> Your committee is unanimously agreed that the information set forth in the reports which have been submitted to us is not conclusive as to the engineering feasibility of the plan outlined in the Swing-Johnson bill, and that before either the government or private capital would be justified on engineering or economic grounds in committing themselves to the expenditure involved the development of the river for the purpose in view should be further and most thoroughly investigated to determine how the results which it seeks to accomplish can be secured with a reasonable assurance of success.

The bill of Senator King of Utah calling for an engineering investigation of the Colorado River situation was summarized in the ELECTRICAL WORLD for April 7 (page 723). On April 11 Representative Douglas of Arizona introduced a bill with a similar motive. It provides that the President shall appoint a board of five engineers of "unquestionable national reputation" who shall "examine into and investigate the Colorado River" and recommend "the most feasible method and cost of obtaining flood control, as to the best systematic program of development." Not more than one appointee shall be or have been in the employ of the Bureau of Reclamation or a resident of any Colorado River Basin state.

The Secretary of War is to build the flood-control structures recommended by this committee, $15,300,000 being appropriated for that purpose, including expenses and salaries of the engineers, but construction shall not begin until the Santa Fe compact shall have been ratified by the seven states and by the Congress, "or until all of said states and the Congress shall have agreed, by compact, that no title to waters, in excess of present perfected rights, which may be stored by such flood-control dam shall be acquired."

## Boulder Canyon Debate About to Start in Senate

As this is written the Senate apparently is ready to take up the Boulder Canyon bill. Prophecies are made that the measure will pass, but it will be in the face of determined opposition which will also have an important effect on the attitude of the House.

Notice was served on the rules committee of the House of Representatives on April 18 by the military affairs committee that if a rule for the consideration of its Muscle Shoals bill is not granted, the measure will be called up on May 2, when the committee will have the call of the calendar.

## United Engineering Society Seeks Endowment Funds

An endowment of $7,000,000 for the Engineering Foundation and the Engineering Societies library is sought by the board of trustees of the United Engineering Society, representing the national societies of civil, mining and metallurgical, mechanical and electrical engineers. One fund of $5,000,000, it is planned, will be applied to the research projects of the Engineering Foundation and a second fund of $2,000,000 to the maintenance of the library.

Secretary of Commerce Hoover has accepted appointment to the endowment committee, of which Col. Edward A. Simmons is chairman.

## Trade Commission Makes Its Second Report

### *Two Thousand Company Responses to Its Questionnaire Already Filed—So Far Little Beyond Routine Information Has Been Elicited*

THUS far in its investigation of the public utilities the Federal Trade Commission has not revealed a single misstatement of fact or any apparent indication on the part of the industries concerned to withhold information sought by the commission. Those who are following the investigation closely are said to be impressed by the fair and businesslike manner in which it has so far been conducted and praise the capacity of Edgar A. McCulloch, the commissioner in immediate charge. The progress which has been made has been facilitated by the ready way in which the utility associations have opened their files and co-operated in every other way.

That the commission has met a ready response to its questionnaire is indicated by the fact that, as made public in its second monthly report to the Senate, two thousand returns already have been filed. In this report the commission announces that additional schedules are being prepared to send to the companies operating in more than one state, to holding companies and to their subsidiary financial, management and construction companies. Special schedules also have been prepared for the municipal utilities. The commission announces that "systematic examination is being made of various sources of information with regard to particular transactions in the electric power and gas industries, in order to develop specific information regarding the growth of capital assets, the methods of issuing securities and other financial matters specifically mentioned in the resolution."

Hearings conducted last week developed only well-known facts. It has been no secret that the utilities have been opposed to the government in business. Full statements of the activities of the Illinois State Committee on Public Utility Information and of the New England Bureau of Public Service and Information were made by B. J. Mullaney, the director of the Illinois committee, who is vice-president of the People's Gas Light & Coke Company and of the American Gas Association; by R. R. McGregor, the assistant director of the Illinois committee, and by Samuel T. McQuarrie of the New England bureau. The testimony brought out that the utilities feel that a public service is being performed in making available the type of information and material handled by such committees, and that it also is necessary to meet unfair attacks and misinformation put out by those who are hostile to the utilities and toward their operation by private enterprise.

During the week representatives of the newspapers owned and controlled by the Copley Press and by Ira C. Copley were heard. Testimony was to the effect that their editorial policies had in no way been governed by outside influence and that no utility had any hand in financing them.

The commission announces that hearings will be resumed April 24, when officers of the National Electric Light Association and the American Gas Association will reappear, together with representatives of the Joint Committee of National Utility Associations.

---

## Cincinnati Rate Reduction

*Union Gas & Electric Ends Litigation by Adoption of Schedule Based on Room Charge—Annual Saving to Consumers of $500,000*

NEW rates which will reduce electric light bills at Cincinnati sufficiently to effect a saving of $4,000,000 in seven years have been agreed to by the Union Gas & Electric Company, Cincinnati, according to a company announcement on April 14. "While feeling secure in its position, legal and otherwise," the company says, "in order to avoid long and expensive litigation for itself and the city, and with a desire to maintain cordial relationship with the consumers of electricity," the proposal, said to be acceptable to all members of the City Council, has been made.

The essential difference between the company's offer and the contested ordinance passed last fall is the basis of the rate structure. The minimum charge in the new rate will be based not on the number of outlets but on the number of rooms. Because it will be necessary for the company to check up on the number of rooms in the home of each of its patrons, the new ordinance will not become effective until September at the earliest, the prevailing rate in the meanwhile being continued.

It is estimated that the reduction involves, with the present number of consumers and their average of consumption, a saving of more than $500,000 a year, but it is calculated that the new basis and form of rates will result in a considerable increase of consumption. The new residence rates include a demand charge of 10 cents per room per month for a minimum of four rooms, plus an energy charge of 5 cents per kilowatt-hour for the first 6 kw.-hr. per room per month and 3 cents for all in excess of 6 kw.-hr. The minimum bill will be 75 cents.

It is understood that with the passage of an ordinance accepting this proposal, which had been scheduled for April 18, all litigation will be discontinued. The rates which the municipality sought to enforce last fall had been enjoined in the federal court pending a hearing. The company had won a suit brought by a taxpayer in the Common Pleas Court, and the municipality had appealed.

# Power Stations Featured at Baltimore

### Regional Meeting of A.I.E.E. Discusses Gould Street Station and Conowingo Development—Dielectrics, Turbo-Generators and Stability Also Among the Topics

MORE than 250 members and guests of the American Institute of Electrical Engineers attended the sessions of the regional meeting held in Baltimore this week.

Electrical insulation and related problems in dielectrics were considered at the opening session on Tuesday. A thermal method of standardizing dielectric power-loss measuring equipment was offered by J. A. Scott in a paper prepared in collaboration with H. W. Bousman and R. R. Benedict. This application involved investigations of dielectric power loss in cables utilizing the sheath temperature rise associated with the flow of heat due to power loss within the sheath. The method avoids the errors involved in the use of a reflecting astatic electrodynamometer wattmeter using an air capacitor for phase-angle compensation.

The practical considerations involved in the application of mica folium to the insulation of coils for high-voltage turbo-generators were pointed out in a paper prepared by C. H. Hill and read by J. L. Henderson.

A further report of determinations regarding the effects and characteristics of residual air and moisture in impregnated paper insulation was made by J. B. Whitehead, W. B. Kouwenhoven and F. Hamburger, Jr., in a paper read by the latter. Discussion ranged largely around this paper, it being contended in general that investigations involving a specially prepared short-length, nonreeled cable sample gave results widely divergent from those obtainable with standard materials and that methods applied here would be inapplicable to production manufacturing. This assumption was discounted by several members, who discerned a tangible advantage in the investigation of basic phenomena under favorable, controlled conditions. Dr. Whitehead disclaimed any attempt to simulate commercial manufacturing conditions in this laboratory work.

A lecture, "Sounds That Burn," was delivered by Dr. R. W. Wood on Tuesday evening, and following this the two regional prizes for the best paper and the best first paper of 1927 were both presented to Sigmund K. Waldorf for his exposition of a new amplifier to adopt the oscillograph to low-current investigations.

The new Gould Street generating station of the Consolidated Gas, Electric Light & Power Company was the subject of the Wednesday sessions. A general description of the features of this plant was presented by A. S. Loizeaux. The design studies which preceded the erection of the first section of the station and the engineering considerations leading to the specification of major items of equipment were detailed by F. T. Leilich. A. L. Penniman, Jr., and F. W. Quarles outlined the problems and experiences encountered in the operation of this station. As this was the first pulverized-fuel installation on the Baltimore company's system the operating personnel was carefully selected. A frank statement of early operating difficulties was made.

The Gould Street plant has several unusual features, including one boiler for each turbo-generator unit, condensers with rolled tubes at both ends, and bleeder heaters utilizing hairpin-loop, single-tube sheet construction. Water-cooled furnace walls are installed. The cost for the ultimate station of 160,000 kw. was given as $79 per kilowatt and the thermal performance obtained is 14,000 to 15,000 B.t.u. per kilowatt-hour.

Prof. A. G. Christie discussed the paper, dwelling on the points just referred to, and pointed out that the use of one boiler to one turbine made the boiler house shorter than the turbine house.

H. C. Sutton said the 450-lb. steam pressure permitted an interesting comparison with present-design plans for the Deepwater station on the Delaware opposite Wilmington, where only 1,380-lb. boiler pressure will be used. L. W. W. Morrow pointed to the unusually large use of automatic control in the plant and especially on the alternating-current auxiliaries, where wide speed ranges were desired.

A. L. Penniman said the station had come up to the expectations of the designers. Heavy maintenance on the pulverized-coal installation was required at first; the heat transfer in air heaters did not come up to expectations; radiation losses were larger than expected, but so was boiler-heat transfer. He said that lessons learned for building a new station were: (1) Do not start up a pulverized-fuel plant in winter. (2) Use 800-deg. to 825-deg. F. steam temperature. (3) Dry all pulverized coal in the preparation mill. It had been shown, he asserted, that all metal-wall furnaces would operate splendidly at very high ratings.

An inspection trip to Gould Street station was made on Wednesday afternoon and a dinner-dance was held that evening. Herbert A. Wagner, president of the Consolidated Gas, Electric Light & Power Company, was the speaker at the dinner. He paid tribute to the engineer and the work he had done to make possible modern life. President Bancroft Gherardi also spoke briefly.

The Conowingo development was covered in three papers presented on Thursday morning, and a large party was booked for an inspection trip there on Friday. On Thursday afternoon system stability and overexcitation were to be discussed, and, in addition, a paper on the communication features of the Conowingo project was scheduled.

## Argument in New Jersey Merger Suit

*Attorney for Public Service Corporation Maintains that the Public Good Should Take Precedence Over Stockholders' Rights Where These Conflict*

ARGUMENT was heard at Newark, N. J., last week before Vice Chancellor Baker in the suit brought by minority stockholders against the merging of five leased companies into the Public Service Electric & Gas Company of New Jersey. As previously reported (ELECTRICAL WORLD, July 2, 1927, page 34), the underlying companies involved are the Essex & Hudson Gas Company, the Paterson & Passaic Gas & Electric Company, the New Brunswick Light, Heat & Power Company and the Somerset, Union & Middlesex Lighting Company. The Public Service Corporation in bringing about this consolidation followed its settled policy of simplifying its organization and capital structure.

Robert H. McCarter, attorney for the Public Service Corporation, argued that the mergers were of benefit to the public and enabled the corporation to borrow money at a lower rate of interest than can be obtained where leased properties are concerned. He challenged the right of any stockholder to seek to prevent a business movement for the public good because the stockholder has an investment in a leased company.

Thomas G. Haight, counsel for the minority stockholders, argued that the merger would relieve the Public Service Corporation from paying rentals on the 900-year leases and that, since Public Service stock would receive dividends only when earned, the stockholders in the absorbed companies would be deprived of their right to an assured return. Mr. Haight maintained also that the market value of the stock of the leased utilities was less a measure of value than the equity behind this stock.

Mr. McCarter asserted that a majority of stockholders in the leased companies favored the merger plan and that only a catastrophe could affect the 6 per cent dividends of the Public Service stock. If such a catastrophe occurred, the leases would have to be canceled anyhow, he declared.

A decision on the case is expected in the near future.

## Electrical Men Meet with Oil Burner Makers

The fifth annual convention and exposition of the American Oil Burner Association, held at the Hotel Stevens, Chicago, on April 3, 4 and 5, brought together 1,500 representatives of the greatest variety of interests ever assembled to discuss the problems of oil heating, including many electrical men. The convention demonstrated that the oil-burner industry is impressing the value of its products upon the electrical industry.

A particularly pertinent address was given by Charles K. Nichols of the New York Edison Company, who spoke of the increased attention which electric light and power companies are giving to the possibilities of oil heating. "There is a great chance," he said, "for the oil-heating industry and the electric light and power central stations to help each other out." Mr. Nichols went on to say that his industry, through the National Electric Light Association and the Association of Edison Illuminating Companies, is investigating oil heating and, if satisfied with the information developed, is preparing to promote the use of domestic oil burners just as it is now pushing electric refrigerators. This interest is due to the desire to equalize the central-station "load."

The fact that the Board of Underwriters has placed its stamp of approval upon a large majority of representative oil burners now in use was cited as proof that the industry no longer need fear opposition to its products on the ground of danger from the burning of oil in domestic heaters. Government statistics were quoted to prove that oil prices today are practically the same as in 1913.

## Plans Forwarded for Chicago Industrial Museum

Impetus has been added to the plans for the Chicago Industrial Museum by the appointment as director of Waldemar Kaempffert, science and engineering editor of the New York *Times*, who will pass several months studying similar museums in Paris, London, Vienna and Munich before taking up his new work.

The Chicago Industrial Museum, which will have 400,000 sq.ft. of floor area — or about the extent that Sir Henry Lyons, director of the Science Museum of South Kensington, London, regards as ideal—has been made possible by a gift of $3,000,000 from Julius Rosenwald in addition to $5,000,000 appropriated by the South Park Commissioners to reconstruct for this use the fine arts building of the World's Fair of 1893. Mr. Kaempffert emphasizes the intention to make the museum more than a heterogeneous collection of machines. It is to be an educational institution for the presentation of scientific and engineering principles.

## Miami Draws 600 Men from Southeast

### Divisional Convention Discusses Merchandising, Rural Service and Other Industry Topics—Invited Speakers Give Outside Points of View

THE Southeastern Division of the National Electric Light Association, comprising North and South Carolina, Georgia, Florida, Tennessee and Alabama, as well as Porto Rico and Cuba, held its sixteenth annual convention on April 11 to 13, at the Roney Plaza Hotel, Miami Beach, Fla. The registration exceeded 600 and many guests of national prominence were present. From every standpoint the convention was one of the most successful in the history of the division.

After President Joe H. Gill had reviewed the year's divisional activities and H. T. Sands, president of the National Electric Light Association, had once more pressed home the duty of service and the need of eliminating public misunderstanding concerning the aims and methods of the industry, John M. Hager, director of market surveys, Domestic Commerce Division of the United States Department of Commerce, addressed the opening meeting on "Government Survey of Industry and Trade in the Southeast." Mr. Hager stated that the South has stepped ahead of the nation in growth since 1914, the South's increase being 307 per cent as compared with an average of 250 per cent in other sections of the country. Harrison Jones, executive vice-president Coca Cola Company, then gave a stimulating talk on merchandising that was well received. Mr. Jones said that 50 per cent of electric appliances were sold by the customers of the utility rather than the salesmen as the customer knows more about them than the salesman. He said that individuals get in the frame of mind to buy from reading advertisements and hearing what other people say about the appliances and that therefore the service of the appliances already sold was an important factor in sales work.

Comprehensive committee reports filled the sessions of Wednesday afternoon. The speech of Dr. J. S. Thomas, director of extension of the University of Alabama, who addressed a joint meeting of the Commercial and Accounting Sections on Thursday, was one of the best at the convention. Dr. Thomas dealt with the importance to culture of modern business methods and inventions. C. E. Greenwood, director of commercial activities at N.E.L.A. headquarters, and E. A. Davis, chairman of the Accounting National Section, also addressed this joint meeting, at which it was resolved to formulate plans looking toward accounting methods which would reflect merchandising costs in a better way.

Major H. S. Bennion, director of engineering of the N.E.L.A., at the Engineering Section meeting outlined what is being accomplished in the co-ordination of communication systems with the power transmission and distribution lines.

At the second general session, on Thursday, John F. Owens, chairman of the Public Relations National Section, spoke on the functions of that section and the chairmen of the Public Relations, Commercial, Engineering and Accounting Sections of the division gave reports, all of which brought forth considerable discussion. An impromptu speaking contest conducted by the women's committee was won by Miss Edith Wise of the Knoxville (Tenn.) Power & Light Company, to whom a free trip to the coming Atlantic City convention of the national association was awarded.

A feature of the third general session was the talk of Phillips B. Shaw, vice-president of the National Electric Power Company, on the operation of the merchandise department in relation to other phases of utility operation. Mr. Shaw thought that since utility companies are pushing their merchandising programs the greatest need is to educate the major executives into regarding merchandise activities as something which can be co-ordinated with the rest of the operations rather than carried on apart from them. He spoke in favor of the district representative methods of operation whereby such representative does service as well as sales work. Another speaker was Miss Eloise Davison, home economics adviser of the N.E.L.A.

Rural electrification was the subject of Forrest D. Banning of the Florida Power & Light Company, who gave an outline of its growth in the Southeast and told about the 120,000-acre small-farm development in Florida of J. C. Penny, where 90 per cent of the farmers are using electricity.

A feature of the entertainment program not common at N.E.L.A. conventions and much enjoyed was the deep-sea fishing. The following officers were elected for the coming year: President, Charles A. Collier, vice-president Georgia Power Company; first vice-president, Stuart Cooper, vice-president South Carolina Power Company; second vice-president, T. H. Tutwiler, president Memphis Power & Light Company; third vice-president, H. E. Cox, Birmingham Electric Company.

## Bay State Lower House May Ask Utility Inquiry

The postponement until next year's session of the bill asked by the Massachusetts Department of Public Utilities to govern rate regulation has not yet been agreed to by the House of Representatives, although the Senate, as reported on April 7 (page 723), adopted the joint legislative committee's report recommending this policy. In the House a substitute resolution was referred to the committee on ways and means, from which at the time of writing it had not been reported.

This substitute resolution provides that an unpaid special commission, consisting of one member of the Senate to be designated by the president thereof, three members of the House of Representatives to be designated by the Speaker, the chairman of the Commissioners of the Department of Public Utilities and two persons to be appointed by the Governor, "shall investigate ways and means for regulating the rates, valuations and capital issues of gas and electric companies in such manner as will be fair alike to the public and to the companies concerned," including the recommendations of the Governor and the department now before the Legislature. This special commission would be instructed to report to the Legislature not later than Dec. 1, 1928, with the drafts of recommended legislation.

## Cooper Applies Again

*Hydro-Electric Engineer Asks Federal Power Commission for Columbia River Permit—Porto Rico Company Seeks License—Storage in National Forests*

HUGH L. COOPER has applied again for a preliminary permit covering a project in "Z" Canyon on Clark's Fork of the Columbia River near the Canadian boundary. The Federal Power Commission, in April of last year, rejected an application from him for a preliminary permit because of the doubt of obtaining state rights and because of the lack of potential market. The objection of the state, which was based upon possible interference of this project with development of the Columbia Basin, has been removed (Electrical World, March 3, page 474), and Colonel Cooper advises that he is now in a position to demonstrate his ability to market the power. About 200,000 hp. of primary power is available at the site, and it is planned eventually to install 350,000 hp. Favorable reports have been submitted by the Forest Service and the Bureau of Reclamation with the usual provisos, and it is understood that a favorable report has been submitted to the War Department.

The Porto Rico Railway, Light & Power Company of San Juan has applied to the Federal Power Commission for a license covering a project intended to develop the power resources of the Blanco, Hicaco, Cubuy, Sabana, Prieto and Sojonto Rivers. This company previously had been denied a preliminary permit, owing to the fact that it was in conflict with an application submitted by A. L. Arpin and because neither applicant at that time had been granted territorial rights. In the meantime the light and power company has completed its surveys and has acquired the necessary franchise in Porto Rico. It is planned to construct a 1,200-acre-foot storage reservoir on the Hicaco into which the waters of the Sojonto and Prieto Rivers will be diverted. A power house will be constructed 1½ miles below the dam. Another dam will be built just below the power house, where another reservoir will be created to impound the waters of the Sabana and Cubuy Rivers. Another power house will be built 2 miles below that dam. It is planned to install 10,000 hp. The project is of particular importance in Porto Rico, where fuel is high.

Action having an important bearing on the rights of water-power licensees who plan to develop storage in national forests has been taken by the Federal Power Commission. In at least one important case private owners of lands lower down the river obtained an injunction against such storage on the ground that a reduction in flood heights affects injuriously the productivity of certain downstream lands enriched by overflow. The commission finds in that case, which affects the San Joaquin River developments of the Southern California Edison Company and the San Joaquin Light & Power Corporation, that these projects are desirable and justified in the public interest for the purpose of improving navigation. Recently this relation to navigation was investigated. It was found that the storage would aid navigation by the reduction of flood flows and by the increase in the low-water flow.

## Adjourn Royal Gorge Hearing Until May 2

Another hearing by the utilities commission of Colorado on the application of the Public Service Company of Colorado to build a hydro-electric plant in the Royal Gorge near Canon City was held at Pueblo on April 12, when Warden Richard Shaw of the State Reformatory, Mayor Alexander and other representatives of Salida, Colo., Chief Engineer Arthur Ridgway of the Denver & Rio Grande Western Railroad, Franklin P. Wood, consulting engineer, Denver, and others opposed the application. Hearing was adjourned to May 2, when testimony in rebuttal will be heard.

## Court Allows Six-Cent Rate at Worcester

Residential and commercial customers of the Worcester (Mass.) Electric Light Company are now being billed at a maximum net rate of 6 cents per kilowatt-hour on meter readings dating from April 1. Judges Bingham, Johnson and Lowell issued a decree last week in the United States District Court at Boston modifying the injunction against the Massachusetts Department of Public Utilities prohibiting the commission from enforcing its decision of last June ordering the company to reduce its maximum rate from 7 to 5 cents per kilowatt-hour. The injunction was modified to permit the company to charge a 6-cent rate as a result of a voluntary reduction from 7 cents recently announced by the utility.

Counsel for the commission and the company agreed upon the modification pending final determination in the federal courts of the propriety of the commission's 5-cent rate. The court finding requires the company to deposit a million-dollar bond for refunds to its customers in case it loses its case and allows the company to charge a 7-cent rate on bills remaining unpaid fifteen days after rendering. On the reproduction-cost-less-depreciation rate-base method the company maintained its right to a return on $17,837,965, while the commission set the maximum base at $10,000,000.

## St. Lawrence Notes Are Made Public

*Kellogg and Massey Arrive at "Acceptable Basis of Negotiation" for Waterway and Power Development—United States to Pay for International Section of River*

FOUR notes on the projected St. Lawrence River waterway exchanged since January by Secretary of State Kellogg and Vincent Massey, the Canadian Minister at Washington, have been made public there and at Ottawa. These notes are formal and in part repetitious of standpoints already taken by the American and Canadian governments. An "acceptable basis of negotiations" is defined in them as follows:

"That the prosecution of the improvement of the St. Lawrence waterway be based on the undertaking by the United States of the deepening of the necessary channels through the interconnecting waters of the Great Lakes and the improvement of the international section of the St. Lawrence both for navigation and for power, and the undertaking by Canada of the construction of the waterway in the sections wholly Canadian, that is, the Welland Canal and the works in the St. Lawrence below the international boundary."

No serious dissent on the part of Secretary Kellogg was made to a contention by the Canadians that the United States bear the somewhat larger portion of the cost of the work still to be done. The Ottawa government, in addition, declared that further consideration was necessary on its part as to some engineering phases of the problem, while other details, for constitutional reasons, required decisions by the Dominion Supreme Court in cases now pending. Mr. Massey asserted, nevertheless, that it was agreed the project was "feasible."

As for hydro-electric power, Canada made clear that "such power as may be rendered available on the St. Lawrence, whether from the wholly Canadian section or from the Canadian half of the international section, shall be utilized within the Dominion to stimulate Canadian industry and develop the national resources." It also declared that "the development of power on the Canadian side should not exceed the capacity of the Canadian market to absorb it."

To this Secretary Kellogg replied that "it would seem that the United States ought to be permitted to develop its power and use its half, the other half to be used by Canada or not as it should desire. The United States," he added, "fully recognizes the right of the Dominion of Canada to the ownership and use of the Canadian share of the power which may be developed in the international section of the waterway, as well as to all that developed in the national section, and it recognizes also that the disposition of the power is purely a domestic question. It recognizes further that this share is an inherent attribute of Canadian sovereignty, irrespective of the agency by which the power may be developed." Elsewhere the Secretary said that the United States "regards as acceptable the proposal that the design and operation of works in the international section of the river be under joint technical control and assumes that the design of all works on the waterway will comply in general with the plans agreed upon by the Joint Engineering Board as embodying the best principles."

A tentative expense table submitted by the Canadian government put the total cost of canalization and ultimate power development (3,148,900 hp.) at $400,830,000 for Canada and $383,183,000 for the United States. The figures for Canada include $85,560,000 representing the existing St. Lawrence and Welland Canals and Sault Ste. Marie Lock.

Addressing the Canadian Parliament, Premier King intimated his sympathy with the project and expressed the view that it was an undertaking bound to be carried out at some time in the course of North American development. It was the first intimation Parliament had had of the Premier's personal attitude with respect to the proposed enterprise.

## Purchases and Mergers

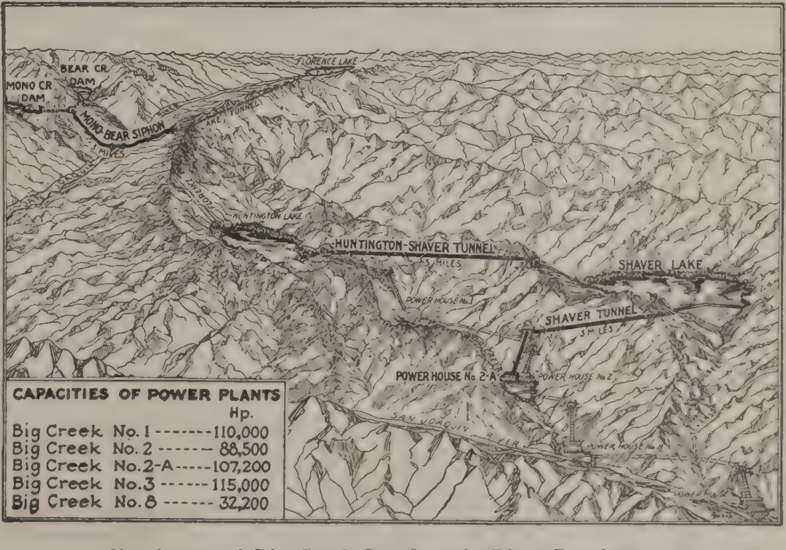
*Penn-Ohio Edison Preparing to Take Control of Northern Ohio Power—Scituate (R. I.) and Corsicana (Tex.) Properties Are Sold*

CONSOLIDATION, long awaited, of the Penn-Ohio Edison Company and the Northern Ohio Power Company began to shape itself into a reality last week when the directors of the former company voted to approve of an exchange of securities of both companies, which exchange will eventually give the Penn-Ohio Edison control of the Northern Ohio Power. A notice calling Penn-Ohio stockholders to a special meeting May 1, at which time formal approval of the transaction will be sought, will be mailed shortly. The Penn-Ohio Edison Company, incorporated in Delaware, has among its subsidiaries the Penn-Ohio Power & Light of Youngstown, the Ohio River Edison Company of Youngstown, the Grand River Electric Light & Power Company of Rock Creek, Ohio; the Zelienople (Pa.) Light &

## Southern California Edison's Advance

### Appropriations for 1928 Include Nearly $6,000,000 Each for Big Creek, for Long Beach and for Transmission-Line Extensions and Substations

INFORMATION from the Southern California Edison Company says that its Long Beach steam plant No. 3 is well advanced and that the first 93,750-kw. unit will be ready for operation about July 1. Foundations for another unit of the same rating are being laid, and the machine has been ordered. Eventually the plant may have eight units and a million horsepower. Construction work on Big Creek power house No. 2A is actively under way, and it will be ready for operation by midsummer. It will contain two turbo-generators with a total rating of 107,200 hp. and will utilize water from Shaver Lake under a drop of 2,419 ft. On account largely of this high head, the penstocks will be of special design and material. An appropriation of $5,982,000 for water-power development and one of $5,987,000 for steam-power development divide the two equally in the 1928 budget, which also provides $3,100,000 for extension and completion of the 220-kv. transmission system and $2,565,000 for betterments to secondary transmission lines and substations.



*Sketch map of Big Creek-San Joaquin River Development completed and in progress*

Power Company and other concerns. The Northern Ohio Power Company controls the Northern Ohio Traction & Light Company of Akron. Hodenpyl, Hardy & Company, to whose group the Northern Ohio belongs; E. W. Clark & Company and Bonbright & Company have agreed to deposit their holdings under the plan of exchange.

Sale of the Scituate (R. I.) Light & Power Company to the Narragansett Electric Lighting Company, negotiations for which had been under way for about a month, was consummated last week. No price was made public. The smaller concern has been obtaining its energy from the larger for some time.

Purchase of the Corsicana (Tex.) Power & Light Company, which controls also the Athens (Tex.) Electric Light & Power Company, by the Texas Power & Light Company is announced.

Permission refused last July (Electrical World, Aug. 6, page 279) by the Pennsylvania Public Service Commission to the Metropolitan Edison Company of Reading to take over eleven other General Gas & Electric subsidiaries has just been extended.

The plan previously published to consolidate the Buffalo, Niagara & Eastern Power Corporation and its associated companies into one operating company was approved by the directors of the various companies at a meeting in Buffalo on April 13. Chief companies included in the consolidation are the Niagara Falls Power Company, Niagara Electric Service Corporation, Buffalo General Electric Company, Niagara, Lockport & Ontario Power Company and Tonawanda Power Company.

John R. Macomber, a director of the International Paper Company, and his associates have, newspaper reports say, acquired the Northeastern Power Corporation's holdings in the New England Power Association, thus giving the International Paper a preponderating influence over the third large stockholder, Stone & Webster. Details of the transaction were not forthcoming.

Approval of the Missouri Public Service Commission has been given to the purchase of the Kirksville Gas, Heat & Electric Company and the Brookfield Gas & Electric Company by the National Gas & Electric Corporation of Battle Creek, Mich. The National Utility Company of Missouri, a newly formed subsidiary of the National Gas & Electric Company, will operate the properties, and the Kirksville and Brookfield corporations will be dissolved. The price reported was $212,500 for Kirksville and $125,000 for Brookfield.

The Mayor of Little Rock, Ark., has reported an offer of the Arkansas Power & Light Company to purchase the municipal lighting plant. He indicated that he would favor the sale if the company will agree to a substantial reduction in rates.

The City Council of Milton, Fla., has called a special election for May 15 to decide whether Milton shall sell its electric plant to the Gulf Power Company for $65,000 and grant the power company a 20-year franchise. The Council has approved the sale, subject to ratification.

The Canada Northern Power Corporation has commenced the consolidation of its component companies—Northern Canada Power, Northern Ontario Light & Power, Northern Quebec Power Company, Great Northern Power Corporation and the Porcupine Power & Telephone Corporation—by issuance of bonds for $15,000,000.

# Briefer News

New 50-Mile Transmission Line for Nebraska. — The Iowa-Nebraska Gas & Electric Company plans to build a transmission line from Blue Springs, south of Beatrice, to Humboldt, Neb. The proposed line will pass through Liberty, Burchard and Armour and cover 50 miles. From Humboldt the company plans to extend its lines to Sterling, Stella, Shubert and Verdon. Construction of the lines will cost about $75,000.

Rochester Gas & Electric Installs Twenty-seventh Substation.—Work will be completed early in May on Station 40, the Rochester Gas & Electric Corporation's twenty-seventh main substation, designed to serve the northeast section of the city. The new station is on Ridge Road, where it will relieve Station 1 of part of its burden, and will have a rating of 3,000 kw., Roger De Wolf, assistant superintendent of the utility, says.

Line from Greggs Falls to Nashua, N. H. to Be Built.—The Public Service Company of New Hampshire will construct a 60,000-volt transmission line from its Greggs Falls station in Goffstown to its station in Nashua, making also a 33,000-volt extension from Hillsboro to Henniker. The line from Goffstown will pass through the towns of Bedford, Merrimac, Litchfield and Hudson. The company already has a trunk line across the state and is now tying in points both north and south.

Public Service Company of Colorado to Erect New Business Building.—The Public Service Company of Colorado has taken out a permit to erect a building at West Third and Lipan Streets, Denver, to house nine departments now scattered in various parts of the city as well as to serve as a garage. The new structure will occupy about two and one-half city blocks and cost $500,000. The executive departments will continue to be housed in the Gas and Electric Building.

American Gas & Electric's Big Program. — No less than $40,000,000 will, according to official announcement, be required to carry out the expansion program now under way for the American Gas & Electric Company's subsidiaries, and a large part of this program will be completed this year. In the total sum are included the seventeen-million-dollar extension to the Philo generating station of the Ohio Power Company, where a 165,000-kw. generator with auxiliaries is being installed, and the new twelve-million-dollar Deepwater station in New Jersey, opposite Wilmington, Del., which is jointly owned with the Atlantic City Electric Company. More than $7,000,000 will be spent on major transmission lines, including the connection of the Indiana General Service Company with the main interconnected system of the American Gas & Electric Company; a 132,000-volt line from Philo to Fostoria, a new high-tension line across south New Jersey and other shorter lines. A number of important substations are being built, and $4,000,000, the company announces, will be spent on local distribution lines and customers' services.

Dublin (Ga.) Rejects Proposal for Competition with Georgia Power Company.—The City Council of Dublin, Ga., has refused the application of a number of business men who asked the privilege of operating a co-operative electric lighting plant to supply light to retail stores in the business section. The Council held that the proposal was unfair to the Georgia Power Company, which is operating under a franchise and investing a considerable amount of money in the city and surrounding territory.

Expansion in New Mexico.—The Texas-Louisiana Power Company has begun the construction of an electric power plant at Jal, N. M., and will connect it with its power transmission system by extending the line which runs from its power plant at Pecos to Kermit. The company has also just finished the construction of a transmission line from its Pecos plant to Fort Stockton, 55 miles, and to Toyah, 20 miles. It is supplying several other towns and the oil fields of this section with electric power.

Another Hydro Plant on the Shenandoah Projected.—The Shenandoah Milling Company of Shenandoah, Va., has obtained options on water rights for a proposed hydro-electric plant on the Shenandoah River, one mile south of Shenandoah. The dam would be approximately 20 ft. in height and 500 ft. long, extending over dry lowland on the east side of the river. The power house would probably be erected on the west side. The milling company recently sold its controlling interest in the Page Power Company's dam at Newport, about 10 miles north of Shenandoah.

Davidson Denies Political Partisanship.—A feature of the Republican primary campaign in Nebraska (referred to last week on page 778) was the appearance of a two-column advertisement signed by J. E. Davidson, general manager of the Nebraska Power Company, who had been accused of supporting Senator Howell, declaring in unequivocal terms that the company was not interested in the candidacy of either the Senator or his opponent and was supporting no one, that it did not belong to any power trust and that no such trust exists in the state.

Second Chelan Unit to Go on Lines About July.—Work is now progressing on the installation of a second 24,000-kw. generating unit in the power station of the Washington Water Power Company at Chelan, Wash. This second unit will be of General Electric manufacture and identical with the first, which was placed in operation last September. The waterwheel is already in place and the generator is scheduled to go on the line about July 1. Both units are fed through a two-mile tunnel, the dam being half a mile below Lake Chelan on the Chelan River. A second tunnel will be required for the further development of this site.

Eighty Additional Miles of Transmission for Southern Maryland.—The Maryland Public Service Commission has granted the Suburban Light & Power Company of Maryland, a newly formed utility, the right to erect 80 miles of transmission lines in three southern Maryland counties, St. Mary's, Charles and Prince George's, to serve a number of communities in that section. The company will purchase its power from the Potomac Electric Power Company of Washington. Decision was reserved on a petition to extend the lines into Calvert County. Such an extension would mean 20 more miles of line.

Table Rock (Mo.) Hydro Project Still Delayed.—More delay in construction of the hydro-electric dam at Table Rock, south of Springfield, Mo., where an ultimate expenditure of many millions is projected, was encountered recently, when the Stone County Court rejected a proposal submitted by representatives of the Empire District Electric Company to build five different sections of road, totaling 37 miles, in lieu of a bridge. The Doherty interests, which are back of these schemes, announced that they are ready to begin construction work as soon as the court waives its objection.

More Plans for Developing Nova Scotia's Water Power. — Announcement that a group headed by I. W. Killam of the Royal Securities Corporation, Montreal, will erect a large newsprint mill in Nova Scotia, probably at Liverpool, has been followed by the news that the Nova Scotia government intends, when the plans for the mill project are finally worked out, to undertake hydro-electric development on the Mersey River, part of the power to be purchased by the newsprint plant. The Mersey is capable of developing about 35,000 hp.; of this the newsprint plant will take about 20,000 hp.

Kewanee a Center of Distribution.—The Illinois Power & Light Company within the next 60 days will complete two more of its 132-kv. steel-tower lines connecting with the Kewanee substation, according to S. M. Cox, general manager at Kewanee. The Keokuk connecting line has been in operation a year and the Joliet line approach was being pushed through, with March 1 as the date for the initial electrification of that loop, but erection of a tower at Bureau, on the Illinois River, delayed this work, which will be finished within two or three weeks. The Peoria line will be cut into the Kewanee station within a few weeks. Half the concrete bases have been finished and 30 per cent of the towers erected. A fourth line, from Rock Island, is to be built later, making Kewanee a center point for these four distribution lines.

Third Unit at Harrah (Okla.) Plant Under Way. — Construction work on the third unit of the Harrah steam-electric station of the Oklahoma Gas & Electric Company near Oklahoma City, which when completed will provide additional generating capacity of 30,000 kw., bringing the station rating to 65,000 kw., is well under way. The original capacity in 1924 when this plant was put in service was 15,000 kw. Work is expected to be completed about Sept. 1, 1928. There are now five 63,000-volt lines through which power is supplied from this station to Oklahoma Gas & Electric Company power users. Two of these lines extend to Oklahoma City, one to Drumright, one to Shawnee and one to the oil fields by way of Etowah.

## *Coming Meetings*

**[A complete directory of electrical associations, with their secretaries, is published in the first issue of every volume. For latest list see Electrical World for Jan. 7, page 80.]**

American Welding Society—Engineering Societies Building, New York, April 25-27. M. M. Kelly, 29 West 39th St., New York.

American Electrochemical Society—Bridgeport, Conn., April 26-28. C. G. Fink, Columbia University, New York.

Missouri Association of Public Utilities—Jefferson City, April 26-28. F. D. Beardslee, 315 North Twelfth St., St. Louis.

Arizona Utilities Association—Prescott, Ariz., April 26-28. M. G. Sanders, Industrial Congress Bldg., Phoenix, Ariz.

Southwestern Public Service Association—Dallas, Tex., May 2-5. E. N. Willis, 403 Slaughter Bldg., Dallas, Tex.

American Institute of Electrical Engineers—New Haven regional meeting, May 9-11; national convention, Cosmopolitan Hotel, Denver, June 25-29. F. L. Hutchinson, 33 West 39th St., New York.

Middle West Division, N. E. L. A.—Hotel Statler, St. Louis, May 9-11. T. A. Browne, 1519 O St., Lincoln, Neb.

Arkansas Utilities Association—Arlington Hotel, Hot Springs National Park, May 14-16. R. I. Brown, Arkansas Power & Light Co., Little Rock.

American Society of Mechanical Engineers—Pittsburgh, May 14-17. Calvin W. Rice, 29 West 39th St., New York.

National Electric Light Association—Atlantic City, June 4-8. P. S. Clapp, 420 Lexington Ave., New York.

American Association of Engineers—Hotel Hussman, El Paso, Tex., June 4-6. M. E. McIver, 63 E. Adams St., Chicago.

Electrical Supply Jobbers' Association—The Homestead, Hot Springs, Va., June 5-8. E. Donald Tolles, 165 Broadway, New York.

National Electrical Manufacturers' Association—The Homestead, Hot Springs, Va., June 11-15. S. N. Clarkson, 420 Lexington Ave., New York.

Pacific Coast Division, N.E.L.A.—Hotel Huntington, Pasadena, Cal., June 12-15. S. H. Taylor, 447 Sutter St., San Francisco.

Georgia Electrical Association—Savannah, June 14 and 15. J. J. McDonough, Georgia Power Co., Dublin, Ga.

Northwest Division, N.E.L.A.—Portland, Ore., June 19-22. B. Snow, 1208 Spalding Bldg., Portland, Ore.

Canadian Electrical Association—SS. "Richelieu" from Montreal to Saguenay and return, June 20-23. H. M. Lyster, 712 Power Bldg., Montreal.

Progress Rapid at Chippewa Falls.—The power-house substructure for the Northern States Power Company's 27,000-hp. hydro-electric development at Chippewa Falls, Wis., is nearly 85 per cent complete, according to Vice-President H. W. Fuller of the Byllesby Engineering & Management Association. The development, of which previous accounts have been printed in these columns, calls for the construction of a dam about 1,030 ft. long and of a power house, approximately 280 ft. x 65 ft., on the north bank of the river. The plant is scheduled for completion Sept. 1 and will operate synchronously with the 42,000-hp. station at Wissota.

New Plant Planned for Texas Utilities Company. — Construction of a main power plant at some point in northwest Texas convenient to its present system of transmission lines and generating plants will be started soon by the Texas Utilities Company, according to J. B. Scott of Plainview, general manager of the company. A survey is now being made to determine the site for the proposed plant, he said. The power transmission system of the company extends to about 40 towns in the Panhandle, South Plains and eastern New Mexico. The company now owns power plants at Plainview, Lubbock and Canyon, all in Texas, and in Clovis, N. M.

Lively Intercompany War at Alliance, Ohio. — Commercial war between the Ohio Public Service Company, a subsidiary of the Cities Service Power & Light Company, and the Suburban Light & Power Company has been carried into two Ohio courts. The Suburban Light & Power was recently purchased by New York capitalists, and its headquarters were moved from Cleveland to Alliance. The Suburban constructed lines to territory where the Stark Electric Company had been distributing power under contract from the Ohio Public Service Company, planning to link its system with the Stark Electric lines. This was halted by a court injunction, and the Ohio Public Service Company is suing for breach of contract. The Ohio Public Service Company in its turn began to branch out in the Alliance territory, constructing a transmission line on a newly improved highway, and its workmen were arrested on trespassing charges. Then the Ohio Public Service Company secured an injunction which prevents the Suburban from removing poles erected by its competitor. The fight has spread to rural service. The Ohio Public Service has been charging rural customers more than $200 each toward line construction. The Suburban has discontinued its connection cost where the property owner agrees to pay $5 a month, for which he can receive 100 kw.-hr., all over 100 kw.-hr. to be paid for at the rate of 5 cents a kilowatt-hour.

Summing Up Nebraska-Iowa Storm.—Final reports from the snowstorm that swept over a considerable portion of eastern Nebraska and western Iowa on April 6 show a total loss to public service companies of more than a million dollars. Of this total $850,000 was the share of communication companies and the remainder that of the power companies, especially the Nebraska Power and the Iowa-Nebraska Light & Power. Nearly twenty-five thousand poles went down. Temporary repairs by nearly two thousand linemen, drafted from unaffected territory, made restoration of service within a few days complete, but it will be several months before permanent work can be completed.

Iowa Public Service Company's Troubles at Sac City and Emmetsburg.—The Iowa Public Service Company and the Sac City (Iowa) authorities have reached an agreement in the litigation involving the location of poles and wires on the streets of the city, the utility company removing its distribution system pending an election at which it is seeking to obtain a franchise in Sac City. If it succeeds, a new system will be installed. At present Sac City, Odebolt and Schaller are supplied with power from the Sac County Electric Company. The Iowa Public Service Company has joined citizens of Emmetsburg, Iowa, in petitioning for an injunction to prevent the Municipal Utilities Company from erecting a municipal plant there. The last-named company agreed to operate the plant until its earnings had paid for the investment, at which time—estimated at eight years—the city was to take it over. The project was indorsed by a three-to-one vote at a special election on March 21.

Salt River Valley Water Users Plan New Hydro-Electric Plant.—The Salt River Valley Water Users' Association will construct an additional dam at Stewart Mountain below Mormon Flat to impound 70,000 acre-feet of water for the operation of a hydro-electric plant. Electric power from this source will go to supplement that which the association is already distributing in that part of Arizona. The Central Arizona Light & Power Company desires to enter into a 50-year contract for the purchase of power from the association at a cost of not less than $240,000 a year, and that company will distribute power to urban communities as well as farms. Owing to the income from power, now mainly from mining companies at Miami, Superior and Ray, the farmers' annual cost of water, on a seven-year average, has been, it is reported, only $3.18 an acre, compared with from $9 to $14 on other reclamation projects.

## Recent Court Decisions

Function of Kansas Courts in Rate Making.—While the courts of Kansas have no rate-making powers, said the Supreme Court of that state in refusing an injunction asked for by the city of Hutchinson against the Hutchinson Gas Company to prevent it from putting a schedule of rates into effect pending the outcome of litigation, they may on proper occasion enjoin non-compensatory rates prescribed by the Public Service Commission and may also enjoin excessive rates promulgated by a utility company; but when a court declares the rates prescribed by the commission confiscatory, a company has the right to prescribe and collect rates of its own making until proper rates have been established by official authority, unless the company's interim rates are also declared unconstitutional. (264 Pac. 68.)*

Municipalities Should Not Operate Utilities at Loss to Taxpayers.—The Iowa Supreme Court, in Muscatine Lighting Company vs. City of Muscatine, has declared illegal an issue of bonds voted by the electors for the purpose of adding additional equipment to the city's electric plant. The company sued as a taxpayer to enjoin the disposal of the bond issue. The court said in part: "The establishment and construction of such a plant is not the exercise of those municipal functions which are in their very nature governmental but the exercise of those which are corporate and proprietary. The municipality in such undertaking incurs or may incur corporate liabilities which may greatly burden the taxpayer. It may therein bind itself by commercial contracts. It in practical operation furnishes heat, water, gas and electrical energy for commercial enterprises. If these are furnished at a loss or if the utility is not profitable, the loss falls on the taxpayer, who thereby is taxed not merely for his proportion of the cost of government, but for the city's loss and (perhaps) consumers' gain in commerce and industry. As a general proposition a municipality ought not to operate utilities at the expense of taxpayers any more than a private corporation ought to operate them at a loss to its stockholders. They should be made to pay their own way and the taxpayers ought not to be called upon to assume a burden that was never intended by the establishment." (217 N. W. 468.)

Poles, Wires, Conduits and Lamps Not Assessable as Real Estate.—The Commissioners of the District of Columbia have lost their appeal in the District Court of Appeals from a decision of the District Supreme Court that the poles, wires, conduits and lamps of the Potomac Electric Power Company are not assessable as real estate. Assessment was made and taxes were levied for the years 1917 to 1926, inclusive, and the power company sued for their cancellation and was sustained in the lower court. The company claimed that the act of 1902 requiring it to pay a tax of 4 per cent on its gross earnings was meant to include all the property of the company not otherwise taxable and covers the poles and conduits located on government property. The court admits that there is conflict of authority as to the exact status of such property of corporations in some states, but points out that the law of the District provides that all real estate shall be assessed in the name of the owner on a valuation to be determined as to each separate tract or lot of land, with the improvements thereon, and says it would require "a stretch of the imagination" to apply this statute to the poles, conduits, wires and lamps of the company erected upon the non-taxable property of the United States.

## Commission Rulings

Poor Agricultural Conditions Bring Reduction in Rates.—The Oregon Public Service Commission has suspended for one year a tariff filed by the Idaho Power Company covering rates charged eastern Oregon consumers for power for limited irrigation pumping service. In lieu of these suspended rates a schedule of service and energy charges approximating a 10 per cent decrease in the original tariff is ordered. An emergency is declared by the commission to exist in this matter on the ground that the territory served by the Idaho Power Company with irrigation pumping service is dry and arid and that for several years the agricultural patrons of the company receiving this class of service have been earning only a meager livelihood.

Hydro-Electric Company's Duty in the Matter of Fishways and Portage for Boats.—Complaint was made to the Wisconsin Railroad Commission that the Neshonoc Light & Power Company had failed to provide adequate fishways around a dam across the La Crosse River, and complaint was also made that no provision had been made for the portaging of boats. The commission dismissed the complaint, saying with respect to the request for fishways that the testimony did not establish the need for any additional facilities of this character, the testimony showing that at periods of high water it was possible for fish to swim up over the apron of the dam in the flow without making a jump of any kind. The company offered to provide access for the purpose of portaging boats around the dam to any persons desiring access for this purpose.

Receipt of Power from Allied Company Disapproved.—Rates of the Amesbury Electric Company have been reduced by the Massachusetts Department of Public Utilities on petition by the selectmen of the town. The utility company was receiving part of its power from an affiliated company, which arrangement the department disapproved, stating: "The great majority of the customers of a public utility are willing to pay a fair and reasonable price for what a commodity or service honestly and rightfully costs, but they do not want the officers and directors of that utility entering into contracts or agreements whereby a private company may profit financially at the public's expense; nor do they want to be required to go to the trouble and expense of a rate case to ascertain whether such private company is so profiting. Such a situation only tends to keep alive that feeling of suspicion and distrust which is not for the best interests of the company or its consumers."

# News About Men of the Industry

### *C. A. Ward Resigns as Head of Vehicle Company*

Charles A. Ward, president of the Ward Motor Vehicle Company, Mount Vernon, N. Y., has resigned to become chairman of the board of the Ward Baking Corporation and also of the Ward Baking Company. Mr. Ward has been identified with the electric vehicle industry for approximately 25 years, organizing in Pittsburgh the business which formed the nucleus for the present Ward Motor Vehicle Company. He studied engineering at Cornell University and early in his career became interested in transportation. In addition to his activities in the electrical field Mr. Ward devoted considerable time to the baking business, having been a member of the board of directors of the Ward Baking Company for a number of years. He has retained his position as a director of the Ward Motor Vehicle Company, but resigned as a director of the Society for Electrical Development after serving that organization for a number of years.

*C. A. Ward*

---

**Willard F. Place** has been elected a director of the Rochester Gas & Electric Corporation, Rochester, N. Y.

**C. Y. Ferris**, of Stone, Webster & Blodget, Inc., has been elected a director of the Blackstone Valley Gas & Electric Company of Rhode Island. He becomes an additional director.

**Dr. John B. Whitehead**, professor of electrical engineering and dean of the school of engineering of Johns Hopkins University, has been engaged as a consultant for the engineering and research staffs of the General Cable Corporation. He is to act in a close advisory capacity on wire and cable insulations and structures and will give particular attention to new developments of high-tension paper cables. Professor Whitehead has, over a period of years, devoted considerable time to cable research and has accomplished results of material benefit to the National Electric Light Association, the Engineering Foundation and the industry as a whole. He has likewise been active in the work of the American Institute of Electrical Engineers and the National Research Council. Professor Whitehead expects to continue his interests and co-operation with such agencies and his university work, but his association with General Cable will be his chief extra-curricular activity.

---

### *E. P. Peck Resigns*

Emerson P. Peck has resigned as vice-president of the Utica Gas & Electric Company, Utica, N. Y., effective May 15. Mr. Peck will join the engineering and development division of the New York Power & Light Corporation in Albany, N. Y. Mr. Peck affiliated himself with the Utica company in 1919 and is responsible for almost the complete reconstruction of the electrical engineering department.

---

**Samuel Insull, Jr.**, president of the Midland Utilities Company, Chicago, and an officer of other utility properties in the Middle West, sailed for Europe April 18 aboard the Cunard liner *Aquitania* for a short sojourn abroad.

**Francis B. Flahive**, formerly assistant treasurer of the Columbia Gas & Electric Corporation, was elected treasurer of the Columbia system. For sixteen years he was associated with Stone & Webster in various financial and managerial capacities. Soon after his connection with the Columbia system in 1927 he was made assistant treasurer.

**George T. Ladd** has been elected vice-chairman of the board of directors of the Combustion Engineering Corporation, New York. Mr. Ladd is an authority on the design and manufacture of steam boilers and has achieved marked success in this field. He is president of the Ladd Water Tube Boiler Company and president of the Heine Boiler Company.

**Edward Reynolds, Jr.**, was recently elected a vice-president of the Columbia Gas & Electric Corporation. He will continue to act as secretary of the corporation and have jurisdiction over its fiscal affairs. Mr. Reynolds was graduated from Harvard University in 1915 and received his early public utility experience with Stone & Webster in Boston, resigning from that position at the outbreak of the World War to enter the U. S. Navy. For 3½ years after the close of the war he was connected with the bond department of the Guaranty Trust Company and in the fall of 1922 joined the Columbia System as treasurer of the Columbia Gas & Electric Corporation.

### *J. C. Boyers New President of Ward Vehicle Company*

J. C. Boyers, formerly vice-president in charge of sales of the Ward Motor Vehicle Company, Mount Vernon, N. Y., has been elected president of that organization to succeed Charles A. Ward, resigned. Mr. Boyers becomes active managing head of the company after an association with the electric vehicle industry which covers a period of fifteen years. Some years ago Mr. Ward chanced upon Mr. Boyers in the vicinity of New Rochelle and induced him to join the Ward Motor Vehicle Company. Mr. Boyers threw in his lot with Mr. Ward and it was not long before he was named vice-president. His activities have not been confined to the transportation field, for he is a director of the American National Bank of Mount Vernon, the Jefferson Title & Mortgage Company and a vice-president of the Community Trust Company.

*J. C. Boyers*

---

**Hugh L. Forman** has been named vice-president in charge of sales of the Ward Motor Vehicle Company, to succeed J. C. Boyers, now president. Mr. Forman was identified with the Ward Motor Vehicle Company for five years prior to the war, but he severed this connection to enter military service. Subsequently he affiliated himself with the Franklin Automobile Company of Syracuse, N. Y.

**William C. Bell**, vice-president of the Rhode Island Public Service Company and general manager of the Narragansett Electric Lighting Company, Providence, has been appointed vice-president of the New England Power Association, with headquarters at Boston, Mass. Mr. Bell was educated at the University of California, and after service with the Pacific Gas & Electric Company and San Francisco Power Company he went to Richmond, Va., in 1911, later becoming general manager of the Virginia Electric & Power Company. About a year ago he was made general manager of the Narragansett company, and has already acquired a high reputation among the younger central station executives of New England.

### *C. A. Collier Heads Southeastern Division*

Charles A. Collier, vice-president of the Georgia Power Company, Atlanta, was elected president of the Southeastern Division of the National Electric Light Association at the convention held during the past week in Miami, Fla. Mr. Collier has been identified with the public utility industry in the Southeast since 1909, the year in which he was graduated from the Georgia School of Technology. Starting as inspector of wiring and motors with the Georgia Railway & Electric Company, he soon was promoted to the position of industrial power sales engineer, and one year later became power sales engineer for large industries. Subsequently, he was appointed assistant to the contract agent of the parent company, the Georgia Railway & Power Company, his special duties being investigation work on customers' power installations, especially on industrial plants.

*C. A. Collier*

After advancing from assistant to the sales manager, assistant to the operating and sales manager and assistant to the general sales manager to the position of general sales manager, he was elected last summer a vice-president of the Georgia Power Company, successor to the Georgia Railway & Power Company, in charge of commercial activities. For many years Mr. Collier has been prominently identified with the Southeastern Division and with local association work in Atlanta.

F. Harper Craddock and C. Maynard Turner, Olympia, have been appointed respectively to the positions of chief engineer and assistant chief engineer of the Department of Public Works of Washington. Mr. Craddock has been with the department for five years. He is a graduate civil engineer from Rensselaer Polytechnic Institute and has had fifteen years' experience on railroad, municipal works and building construction and appraisal work in various sections of the United States. Mr. Turner has had several years' experience in the distribution and operating departments of the largest private and municipal electric utilities in the Northwest and was, for two years, employed as sales engineer for the Westinghouse Electric & Manufacturing Company.

Victor H. Tousley of Chicago has been appointed to the position of electrical field secretary of the National Fire Protection Association, succeeding in this capacity W. J. Canada, who is now identified with the National Electrical Manufacturers' Association. Mr. Tousley will assume his new duties on May 1, 1928, and will temporarily have an office at the Underwriters' Laboratories, Chicago. He is widely known throughout the country in electrical circles. Mr. Tousley has been associated with the department of gas and electricity of the city of Chicago for the past 25 years and for the past fifteen years has been chief electrical inspector of that department. He was graduated from the American Institute of Technology, Chicago, as electrical engineer, is the author of a series of books on electrical construction and has been a frequent contributor to technical magazines. He has for many years been an active member of the Western Association of Electrical Inspectors, of which organization he was president from 1910 to 1912. He has been a member of the electrical committee (National Electrical Code) of the National Fire Protection Association for the past fifteen years. Mr. Tousley is past-president of the Electric Club of Chicago.

### *S. B. Swan General Manager in Providence*

Samuel B. Swan, formerly electrical engineer and more recently superintendent of distribution of the Narragansett Electric Company, Providence, R. I., has been appointed general manager of the company, succeeding W. C. Bell. Mr. Swan has been in the service of the company for eighteen years and is one of the best-known electrical engineers in the New England utility field. He has played an important part in the development of the Narragansett system from an urban property to an extended organization serving a large portion of the state and today forming a vital part of the New England Power Association system. Mr. Bell has assumed new duties in Boston.

*S. B. Swan*

## Obituary

William Robert Quinn, well-known designer of fuel-oil-burning equipment, died suddenly in his room at the Hotel Manger, New York, April 12. Mr. Quinn had been a resident of San Francisco for several years past, having gone there as the Pacific Coast representative of the Combustion Engineering Corporation. He was in New York on a business trip at the time of his death. Mr. Quinn was president of the Quinn Oil Burner & Torch Company until this company was purchased by the Combustion Engineering Corporation in 1922.

A. L. Broomall, manager of the renewal parts engineering department of the Westinghouse Electric & Manufacturing Company, died April 10 at his home in Wilkinsburg, Pa., from pneumonia. Mr. Broomall's first important work was on the installation of the first electric locomotives on the New York, New Haven & Hartford Railroad. From 1911 to 1915 he had charge of the design of electric vehicle motors and then he was appointed section head of the direct-current motor section. In 1922 he was transferred to the renewal parts engineering department as engineer in charge, later becoming manager of the department, which position he held when he died. He was a member of the A.I.E.E.

Charles E. Corrigan, for many years a prominent figure in the manufacturing branch of the electrical industry, died suddenly in Jacksonville, Fla., March 24 following an operation. Mr. Corrigan was formerly vice-president of the National Metal Molding Company, Pittsburgh, but he retired in 1926 from active work, removing to Sarasota, Fla., where he became interested in poultry culture. During his career Mr. Corrigan devoted considerable time to association work, being especially interested in the affairs of the Associated Manufacturers of Electrical Supplies. He was considered an authority on concentric wiring and for many years held the chairmanship of the conduit section of the Associated Manufacturers of Electrical Supplies as well as membership on many other committees of that organization and on the board of governors. Mr. Corrigan relinquished his association activities when he retired and established a residence in Florida.

# Financial and Statistical News

## *Decline in General Market Utility Stocks Strong*

WITH transactions on the Stock Exchange still running in the neighborhood of 4,000,000 shares daily, selling pressure made itself felt during the past week and the market moved downward. In spite of the trend of the general market the light and power stocks held firm and substantial gains were recorded by many. The index of common stocks of fifteen representative light and power companies advanced five points over the preceding week. Brooklyn Edison advanced eight points, Columbia Gas & Electric ten, Detroit Edison ten, Public Service Corporation of New Jersey ten and Pacific Gas & Electric six. The Electric Bond & Share group was conspicuously strong. Electric Bond & Share securities advanced 36 points during the week under review, from 90 to 126, and Electric Investors advanced eleven points, from 49 to 60. General Electric showed marked progress and A. T. & T. rose to the highest level in the history of the company on the New York Stock Exchange, reaching 190¼.

## Utility Stocks Popular with Investment Trusts

Pointing out that the effect of investment trust buying is very important in the present securities market, the Babson Statistical Organization, Babson Park, Mass., bulletin of April 10 tabulated the popularity of public utility common stocks and various industrial, railroad and oil stocks held by five or more in a group of 31 investment trusts which make public their holdings. The number of trusts holding utility stocks and the companies represented follow:

American Telephone & Telegraph, 15; Consolidated Gas of New York, 13; North American, 12; American Gas & Electric, 10; American Power & Light, 9; Brooklyn Edison, 9; Columbia Gas & Electric, 9; International Telephone & Telegraph, 9; Southern California Edison, 9; Western Union Telegraph, 9; Detroit Edison, 8; Public Service of New Jersey, 8; Standard Gas & Electric, 7; Commonwealth Power, 6; National Power & Light, 6, and United Gas Improvement, 6.

Six trusts hold 180,000 shares of American Gas & Electric, four trusts hold 450,000 shares of American Power & Light and three hold 539,000 shares of National Power & Light. Among industrials, seventeen investment trusts hold General Electric and ten Westinghouse stock. Commenting on the quality of the holdings, the report says:

> These trusts hold (in all classes) several billion dollars worth of stocks. . . . In a way the compilation represents the consensus of opinion as to the best stocks for permanent holding. While all of the investment trusts represented in this compilation are not necessarily the largest or the most conservative, nevertheless the combined results of this study should be fairly representative of all investment trust holdings. . . . The class of securities most held is very good indeed and the large volume of trust buying has undoubtedly been a big factor in pushing up the prices of these stocks to present high levels. On the other hand, when the next period of liquidation comes, these holdings by investment trusts will not prevent drastic declines in stock prices.

# New England Power Association Expands

MATERIAL progress in development of additional generating capacity, in improvement of transmission facilities and in enlargement of outlets for power featured the activities of the New England Power Association in 1927. In his annual report to stockholders Frank D. Comerford, president, states that the policy of investing in distributing companies has brought satisfactory results to the system and to the consumers served. The management "has entire confidence in the future of New England and is making plans to engage in further large development of generating capacity and transmission facilities to serve the increased load anticipated." During the past year the association has acquired controlling interests in the Lowell (Mass.) Electric Light Corporation and the Webster & Southbridge Gas & Electric Company. The most important construction work undertaken was the 60,000-hp. hydro-electric plant on the Connecticut River at Bellows Falls, Vt. Thanks to the thorough development and regulation of the Deerfield River by the New England Power Company the November flood did little damage in the immediate section of New England, and flood conditions did not materially affect other plants of the system. A large amount of line and substation construction was completed during the year and an important tie-in was made between the system and the United Electric Railways plant at Providence, R. I. Sales of power show a gain in output for the year, despite somewhat uneven industrial conditions.

The gross operating revenue, eliminating intercompany sales, was $27,378,

*Net before depreciation and federal income taxes.

251; other income, $1,400,409, and total income, $28,778,661. Expenses other than maintenance, depreciation and taxes were $10,827,403; maintenance, $2,782,269; depreciation, $2,687,083, and taxes, $2,523,271, leaving net earnings before interest and dividends, $9,958,633. Net consolidated earnings after interest and preferred and class A dividends of subsidiaries were $4,477,934. Preferred dividends of the association totaled $1,910,421, leaving $2,567,512 net earnings applicable to common shares, or $3.37 per share. Gross assets were $210,237,106, of which capital assets accounted for $181,310,871. The stabilizing effect of the diversification of the system's electrical load is indicated in the following percentage analysis of its revenue from sales of electricity for the year 1927: Public utilities, 17.1; industrials, 47.2; railways, 3; miscellaneous, 4.97 and residential and commercial lighting, etc., 27.8. The number of electric customers increased during the year from 167,805 to 190,830, and the total energy generated and purchased from 1,071,422,000 kw.-hr. to 1,104,518,000 kw.-hr. Over 250 communities having a population in excess of 2,500,000 are served by the system, either directly or through contracts with local distributing companies. The major portion of the energy sold by the system is in large blocks under long-term contracts to many prominent industrial concerns and local distributing companies. The table which appears on page 835 shows the growth of the properties now comprising the system.

NEW NO-PAR PREFERRED ISSUE APPROVED FOR BUFFALO, NIAGARA & EASTERN.—The Buffalo, Niagara & Eastern Power Corporation has filed a certificate at Dover, Del., increasing the authorized capitalization by 500,000 shares of $5 cumulative dividend first preferred stock of no par value. According to present plans not more than 350,000 shares of this new stock will be issued to acquire by exchange or to provide funds for the redemption of preferred stock of the Niagara Falls Power Company, the Niagara, Lockport & Ontario Power Company and the Tonowanda Power Company.

## Macomber Heads N.E. Power Minority Interest

Arrangements have been consummated under which a group of Boston business interests, headed by John R. Macomber of Harris, Forbes & Company, will take over the minority holdings in the New England Power Association hitherto in the hands of F. L. Carlisle & Company, the Northeastern Power Corporation and Stone & Webster, Inc. These holdings compose about 40 per cent of the common stock of the association. The holdings of the International Paper Company in the association remain undisturbed. These represent about 45 per cent of the common stock. The new group is friendly to the present management of the association, as is the International Paper Company.

---

PUBLIC SERVICE PRODUCTION ELECTS DIRECTORS.—At a meeting held April 17 the Public Service Production Company, Newark, N. J., elected the following directors: Dwight P. Robinson,

Samuel T. Bodine, Arthur W. Thompson, Paul Thompson, J. E. Zimmermann, Thomas N. McCarter and Percy S. Young. These men, all prominent in public utility circles, are on the directorate of the United Engineers & Constructors, Inc., organized early this year.

---

CINCINNATI STOCKHOLDERS APPROVE CONSOLIDATION. — Stockholders of the Cincinnati Gas & Electric Company have approved the consolidation of their company and the Columbia Power Company into a new corporation named the Columbia Gas & Electric Corporation. They will exchange their $100 par stock on an even basis for 5 per cent preferred stock of the new corporation, as announced previously in the ELECTRICAL WORLD.

ALLIS-CHALMERS INCREASES CAPITAL. —The Allis-Chalmers Manufacutring Company is planning to increase its authorized capital stock to $50,000,000 from $26,000,000. A meeting of stockholders to vote on the proposed increase has been called for May 3. It is not contemplated that any portion of the proposed additional stock will be issued at this time, but directors deem it advisable to have such unissued stock available for possible requirements in connection with future expansion and development.

---

AMERICAN ELECTRIC POWER INCREASES STOCK.—The American Electric Power Corporation has filed a certificate at Dover, Del., increasing its authorized capital stock (no-par value) from 415,000 shares to 515,000 shares.

CONNECTICUT COMPANY TO CHANGE SET-UP.—President Samuel Ferguson's recommendation to increase the capital stock of the Connecticut Power Company and reduce the par value of the stock was recently approved by the directors. A stockholders' meeting early in May is expected to provide for a capital increase of $3,000,000. New shares will then be issued in the ratio of one for five at par and the par value reduced from $100 to $25. At first it is planned to increase the capital from $5,800,000 to $7,000,000. This is an increase of $1,200,000, and the balance of the proposed $3,000,000 capital increase will be authorized for any future circumstances that may arise. This action is to provide for the acquisition of shares of the Union Light & Power Company, Unionville, Conn., and the

$25 par value will make a wider distribution of stock possible. It will also be in line with the reduction of par value made by the Hartford Electric Light Company, a closely allied company.

## Standard Gas to Change Set-Up

Stockholders of the Standard Gas & Electric Company will be asked to vote May 16 on a proposal to change the 500,000 shares of 7 per cent prior preference stock of $100 par value to 750,000 shares of no-par prior preference stock. A change in the authorized amount of 8 per cent cumulative preferred stock from 600,000 shares of $50 par value to 1,500,000 shares without par value will also be considered.

## New Capital Issues

The largest electric light and power issue of the year was offered by the Associated Gas & Electric Company in the form of convertible 4½ per cent gold debentures, a piece of financing involving a total of $63,000,000. Proceeds will be used to retire debentures outstanding and securities of subsidiaries, for the acquisition of property and for other corporate purposes.

A ten-million-dollar issue was offered by the Shawinigan Water & Power Company in the form of first mortgage and collateral trust sinking fund gold bonds, priced at 98½ and accrued interest, yielding about 4.60 per cent.

During the week ended April 19 the Central States Electric Corporation issued 6 per cent cumulative preferred stock to the amount of $10,000,000 at 101 a share and accrued dividend, to yield 5.94 per cent. Each certificate, representing preferred stock, will carry a stock purchase warrant (non-detachable prior to Nov. 1, 1928) entitling the holder, subject to the provisions of resolutions to be adopted by the directors authorizing the issue of such warrants, to purchase from the Central States Electric Corporation on or before May 1, 1933, one share (without par value) of common stock of the North American Company for each share of preferred stock.

ENGINEERS PUBLIC SERVICE INCREASES COMMON.—Stockholders of the Engineers Public Service Company, at a special meeting held April 12 at Wilmington, Del., voted to increase the authorized common stock from 1,500,000 to 3,000,000 shares, of no par value, and approved amendments to the charter permitting consummation of the $35,000,000 refinancing plan proposed by the directors. Under this plan all of the company's $7 dividend no par preferred stock will be called and replaced by an issue of $5 dividend convertible preferred stock. The directors, meeting at New York after the stockholders' action, voted to call the $7 dividend preferred stock on July 1 at 110 and accrued dividends. There are 310,468 preferred $7 dividend and 797,240 common shares now outstanding.

AMERICAN SUPERPOWER WILL PAY STOCK DIVIDEND.—The directors of the American Superpower Corporation declared a stock dividend to holders of class A and class B common shares of record April 23, consisting of one share of preference stock for each five shares of common stock held. This declaration of the directors followed authorization by the stockholders of the corporation of an issue of 400,000 shares of no-par $6 cumulative preference stock.

BALTIMORE STOCKHOLDERS APPROVE INCREASE IN CAPITAL STOCK.—Stockholders of the Consolidated Gas, Electric Light & Power Company of Baltimore approved the proposed increase in total capital stock to 1,500,000 shares from 1,450,000 shares, the additional 50,000 shares to be classified as 5 per cent series A preferred. They also authorized the directors to issue any number of shares of stock of one or more classes from time to time as the directors deem advisable.

## Cities Service Plans $50,000,000 Loan

With the purpose of refunding outstanding securities and enlarging the company's activities Cities Service Company is planning a fifty-million-dollar issue of 5 per cent debentures, one of the largest pieces of public utility financing of the year. Public offering of the issue is expected within a few days.

KANSAS CITY COMPANY INCREASES CAPITAL.—At the recent annual meeting of the stockholders of the Kansas City Power & Light Company the board of directors was authorized to increase the common stock of the company from 350,000 to 600,000 shares.

## Utilities Well Represented on New Legal Bond List

The securities listed below have qualified as legal investments for savings banks and trust funds in New York State, according to the tentative list issued by F. H. Warder, Superintendent of Banks.

ALABAMA POWER—1st mtge. lien & ref. 5s, 1951; 5s, 1956; 1st mtge. 5s, 1946; 1st & ref. 4½s, 1967.

# Business News and Market Conditions

## First Quarter Contracts Increase 25 per Cent

*Increases Reported from All Sections—Contracts 41 per Cent Greater than in February and 38 per Cent More than in March, 1927.*

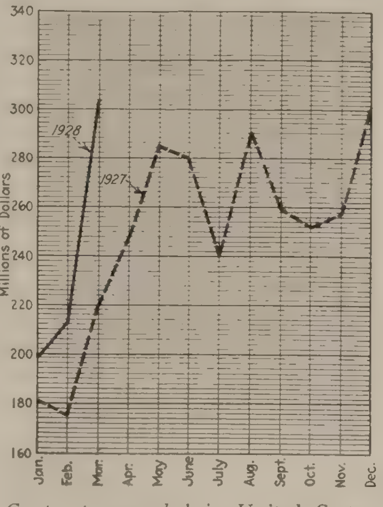
EVERY section of the country showed a gain in engineering construction contracts during March when compared with average weekly figures for February. Increases ranged from 97 per cent in New England to 11 per cent in the South. Compared with a year ago, March totals showed increases in all sections, except west of the Mississippi, where a 15 per cent decline was recorded. Contracts reported by the *Engineering News-Record* during the five weeks of March, 1928, totaled $379,521,000.

The outstanding feature in the awards let during March, 1928, was the large commercial building total for the Middle Atlantic states. This value, $113,428,000, constituted 30 per cent of the total awards. The average monthly commercial awards in that section during 1926 were $40,335,000, in 1927 $52,440,000 and thus far in 1928 $72,300,000. Several of the large March contracts were: In New York, office and store, $23,000,000; office and printing, $6,000,000; apartment hotel, $6,000,000; in Chicago, office and printing, $10,000,000; theater and office, $20,000,000; club, office and store, $4,000,000. There were 25 commercial building awards outside of New York City that exceeded $1,000,000, and these totaled $32,650,000. New York commercial awards totaled $81,451,000 and Illinois awards totaled $43,236,000.

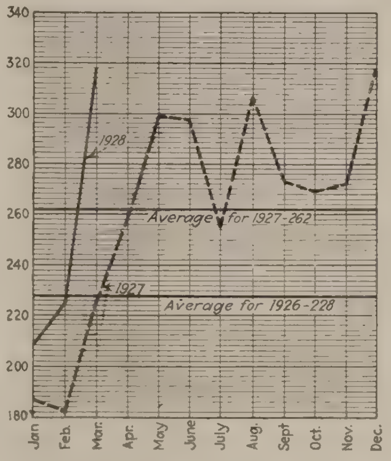
Total private awards for March, 1928, exceeded those of a year ago by 56 per cent, whereas only an 8 per cent increase is shown in public contracts. The summer months are peak months for public awards because of the large volume of street and road work, which thus far in 1928 constitutes 47.5 per cent of all public contracts. Public contracts in 1928 and 1927 to date respectively are $241,748,000 and $205,171,000.

The construction volume index number for March is 318. This compares with 228 for the whole of 1926, 262 for all of 1927 and 100 for 1913. This means that the actual volume of contract letting in March, 1928 (not the mere money value of the contracts let), is 218 per cent greater than the volume for 1913. The index number contains the increment of construction and indicates the rate at which contracts are let, as compared with 1913 awards.

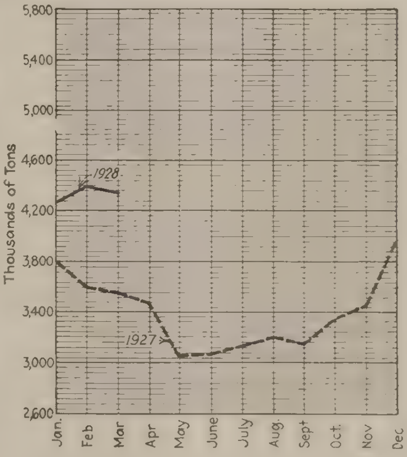
Unfilled orders of the United States Steel Corporation showed a decrease in March. The trend in 1927 and to April 1, 1928, is indicated in the accompanying curve. The decrease was smaller than anticipated and indicates increased buying late in March.



*Contracts awarded in United States*



*Construction volume as compared with an index of 100 for 1913*



*Unfilled tonnage as reported by the United States Steel Corporation*

In the chart at the left the actual volume of construction is compared and not the mere money value of contracts let. (*Engineering News-Record* statistics.)

*Value of Contracts Let in the United States and Canada During March, 1928*

Thousands of dollars (000 omitted)

| | New England | Middle Atlantic | South | Middle West | West of Mississippi | Far West | United States | Jan. 1 to Date, U. S. | Canada |
|---|---|---|---|---|---|---|---|---|---|
| Waterworks | .... | $567 | $148 | $623 | $899 | $466 | $2,703 | *$7,365* | $144 |
| Sewers | ..... | 1,208 | 201 | 3,999 | 996 | 1,765 | 8,169 | *13,120* | 253 |

NOTE.—Owing to five weeks of construction contracts being included in some months, as in March, the figure for the total contracts let, as shown in the table, does not agree with the figure as represented in the curve. In order to obtain comparable figures the curve is worked out on a four-week basis for each month.

# Market Conditions

IN NEW ENGLAND central-station companies are prominent buyers. Insulator sales in that district were reported at a peak last week. Small motor sales reached a total of over $50,000. Good central-station buying continues in the Eastern district. Prime movers are in demand. Sales include a 5,000-kw. unit, costing $55,000, for northern New York and a 70,000-kw. unit, costing $750,000, for a Middle West company. A metropolitan central-station company also bought $50,000 worth of transformers. Railway business is beginning to loom as an active factor in the market.

Large power equipment orders are anticipated in the Southeast. One company plans the immediate purchase of $1,000,000 worth of generating equipment. A steel mill in Alabama purchased $45,000 worth of motors and an iron mill in the same state ordered $20,000 worth of automatic substation equipment. In St. Louis manufacturers report the demand for motors and equipment above normal. A slight increase in business is noted in the Middle West, with industrial activity somewhat spotty. On the Pacific Coast power company buying is fair and street-lighting sales are active.

## *Central Stations Prominent in New England Buying*

Sales of electrical equipment in the New England district have continued with encouraging signs of activity. Central-station needs have added vigor to the market. Many small orders were reported. Bus supports, disconnecting switch orders, small switches, outside requirements, insulators, cable and wire were in good demand. A prominent manufacturer reports insulator sales at a peak during the past week. Orders for general replacement equipment included one for an eastern Massachusetts substation for $2,000 and another for a central-station company in Maine for $1,500. One of the largest manufacturers in the district records a steady gain in inquiries. Small motor sales reached a total of over $50,000. A few large motors were ordered during the week.

Heavy industrial equipment sales are quiet, but indications point to a number of interesting orders that will be placed shortly. The plans for the addition to the Edgar station include provisions for a 10,000-kw. turbo-generator unit as well as two high-pressure boilers rated 1,400 lb. per square inch. Construction projects are as follows:

The Public Service Company of New Hampshire, Manchester, plans to construct interconnecting lines, one of 66,000 volts connecting the Griggs Falls plant with Nashua and a 33,000-volt line connecting Henniker with Hillsborough. The Randolph and Holbrook Power & Electric Light Company, Randolph, Mass., is planning to build a substation in Holbrook, Mass. Springfield, Mass., has authorized $234,000 for an electric pumping plant for municipal water works.

## *Large Power Equipment Order Expected in Southeast*

No purchases out of the ordinary are reported for central-station companies in the Southeast. One company ordered fiber conduit amounting to $6,700, aluminum cable totaling $2,100 and creosoted pine poles valued at $4,300. An order approximating $30,000 for cotton gin motors for a Mississippi power company is in immediate prospect and will probably be placed this week. An Alabama power company has asked for bids on three waterwheels and generators, with a total capacity of 90,000 kva., and contracts will probably be let the early part of May.

Construction contracts have been let on the two new viaducts in Atlanta and the sub-contract on electrical work will undoubtedly be let within the very near future. The electrical materials required on this project will total about $35,000. Bids are in on school building construction amounting to about $1,000,000 in Atlanta and contracts are to be let this week.

A steel mill in Alabama that is revamping its plant ordered motors amounting to $45,000 and an iron mill in the same state ordered $20,000 worth of automatic substation equipment. A cotton mill in the Carolinas ordered motor equipment costing $2,500. Purchases by contractors are slow, such orders as are being received coming from the larger contracting firms. One contractor ordered $6,000 worth of wiring materials for one job in middle Georgia. Construction projects are as follows:

The Erwin Manufacturing Company, Huntsville, Ala., plans addition to textile mill, to cost $100,000. The Columbus Electric & Power Company, Columbus, Ga., is planning hydro-electric power plants on the Chattahoochee River, near Maple Creek and Harrison Island, respectively, to cost $1,000,000. The Lindsay-McMillan Company, Milwaukee, Wis., plans an oil refining plant near Savannah, Ga., to cost $150,000. Rolling Fork, Miss., will receive bids May 1 for equipment for municipal power plant. Columbia, N. C., is asking bids until May 7 for equipment for municipal lighting plant. Shelby County Commissioners, Memphis, Tenn., plan mechanical shops for the County Workhouse, to cost $400,000. Union City, Tenn., plans early installation of a 1,000-kw. turbo-generating unit. The American Creosoting Works, Inc., Norfolk, Va., plans a creosote distilling plant, to cost $150,000. The Gauley Power Company, Charleston, W. Va., plans a 60,000-hp. hydro-electric power plant on the Gauley River in Fayette County, to cost $900,000. Martinsburg, W. Va., plans a municipal power plant. Hazelhurst and Meridian, Miss., will install ornamental lighting systems.

## *Prices Continue Firm in Dull Metal Markets*

Absence of buying interest accompanied by unchanged or, in some cases, slightly higher prices, featured the non-ferrous metal markets during the week ended Wednesday. Lead has been quiet but steady at 6.10 cents, New York, and 6 cents, St. Louis; some activity is reported in tin at slightly better prices and the tone of the domestic zinc market is better as a consequence of some improvement in prices in London. Antimony quotations are fractionally higher.

NEW YORK METAL MARKET PRICES

| | Apr. 11, 1928 Cents per Pound | Apr. 18, 1928 Cents per Pound |
|---|---|---|
| Copper, electrolytic.... | 13.9625 | 13.9875 |
| Lead, Am. S. & R. price | 6.10 | 6.10 |
| Antimony............ | 9.625 | 10.00 |
| Nickel, ingot.......... | 35 | 35.00 |
| Zinc spots............ | 6.075 | 6.10 |
| Tin, Straits........... | 51.875 | 52.50 |
| Aluminum, 99 per cent | 24.30 | 24.30 |

Base copper wire price April 18, 1928, 16 cents.

## *Good Central-Station Buying in Eastern District*

Power company business is a feature of current business in the Eastern district, not only with regard to actual contracts but in connection with inquiries for early commitment. Prime movers are again in demand, with substation equipment and line materials close seconds in volume sales. The outlook for continuance of the present buying movement is decidedly encouraging. A central-station company in northern New York has placed an order for a 5,000-kw. turbo-generator, with accessories, totaling about $55,000 and a Middle West power company has contracted for a 70,000-kw. unit of like type with the same manufacturer, the order aggregating $750,000. An order for transformers has been given by a metropolitan central-station company to an amount which will be approximately $50,000.

A New York company has secured an order for the steam end of a municipal power station project in Missouri, covering boilers, stokers, forced draft equipment, etc., amounting to $30,000. The contract for the turbo-generator installation for the same plant in Missouri has been given to a Pittsburgh manufacturer at $41,000. Control apparatus for central-station service is in improved demand, following rather spotty conditions for several weeks past. A leading maker has secured a contract for equipment of this kind for a New York power station, costing approximately $60,000.

Railway business is beginning to loom as an active factor in the market. Actual buying is expected to mature within the next four to six weeks. It is anticipated that the New York Central Railroad Company will be in the market for equipment for the electrification of its west side lines in New York at an early date. The decision of the Pennsylvania Railroad Company to expend $20,000,000 for a new passenger terminal and line improvements at Newark, N. J., is another project of particular importance. Immediate construction activities in the Eastern district include the following:

The United Electric Light & Power Company, New York, plans for a distributing plant on 134th Street to cost $60,000. The LaClede Company, Buffalo, N. Y., will build an addition to its paper and card factory to cost about $100,000. The Signal Corps Laboratory, Fort H. G. Wright, N. Y., is asking bids until April 30 for 16,000 ft. of submarine cable (Circular 4). The Royle & Pilkington Company, Mount Holly, N. J., plans a new textile mill at Hazlewood, N. C., to cost $125,000. The Roller Bearing Company of America, Inc., Newark, N. J., has acquired the former plant of the Mercer Motor Car Company, Trenton, N. J., and will remove and expand its works at a cost of $350,000. The Bureau of Water, Philadelphia, Pa., is asking bids until April 26 for switchboards, electrical instruments, etc., for the Belmont pumping station (Contract No. 917); also, at same time for motor-driven pumping machinery (Contract No. 916).

The Baltimore & Ohio Railroad Company will make extensions in shops at New Castle, Pa., to cost $150,000. Washington and Jefferson College, Washington, Pa., plans a two-story chemistry building to cost $225,000. The Philadelphia Suburban-Counties Gas & Electric Company will install a power switching station at Bridgeport, Pa., in connection with service from the Conowingo hydro-electric power project. The Board of District Commissioners, Washington, D. C., is asking bids until April 25 for motors, starting equipment, etc., in connection with pumping machinery for the municipal sewage system. The General Purchasing Officer, Panama Canal, Washington, is asking bids until April 27 for dome refractors, electric refrigerators, etc. (Panama Schedule 1870.)

## *Street-Lighting Sales Active on Pacific Coast*

Recent power company orders on the Pacific Coast include one carload of 60,000-volt pin-type insulators for $8,000 and one carload of 11,000-volt units for $3,500, both for installation along the central area of the Coast range. A contract placed by Truckee for installation of a light, heat and power system amounted to $9,372. The power company load drive is reflected in a San Francisco jobber's purchase of 210 ranges, valued at $22,500, for stock.

Street-lighting business amounted to nearly $30,000. An order for 51 assorted motors, from 5 hp. to 150 hp. and valued at $15,000, has been placed for Hawaiian shipment. Prospective business includes complete electrical equipment for the Oakland Estuary subway, airway beacons and landing equipment for all the emergency fields on the airway routes between San Francisco and Blue Canyon and San Francisco and Redding, a $500,000 oil distributing plant in San Jose for a Doheny subsidiary, a $2,000,000 expenditure by San Francisco for new firehouses and high-pressure extensions, a 10-mile pole line job for Stanford University, a 45-mile farmers' telephone line for Raymond and a 15-mile similar line for Lemoore, a $2,000,000 factory and plant for Johns-Manville at Pittsburg, Calif., and a $1,000,000 hotel and bungalow colony near Indio on the edge of the California desert.

Sales of motors and pumps for orchards and irrigation districts in eastern Washington continue exceptionally brisk. Other motor business is quiet. Range sales reported average about 750 per month in Seattle alone and domestic appliances are in good demand. Specifications are reported out for approximately 50 motors, 25 hp. to 15 hp., for an Idaho lumber mill and for 30-in. butterfly valves, pumps and motors for a pumping plant for the U. S. Indian Irrigation Service at Wapato.

The city of Seattle is taking bids for 175,000 ft. of guy wire and 10,000 eight-pin cross-arms. The Mountain States Power Company, Tacoma, Wash., plans an expenditure in excess of $100,000 in improvements to light and power service in Coos Bay, Ore. The Northwestern Pulp & Paper Company is reported to have signed a contract with the Austin Company for a 100-ton pulp mill at Astoria, Ore. Construction projects are as follows:

The Willys-Overland Company, Toledo, Ohio, will build an assembling plant at Los Angeles, to cost $1,000,000. The Floco Motors Corporation, Los Angeles, Calif., recently organized, plans an automobile manufacturing plant to cost $150,000. The Continental Can Company, San Francisco, Calif., plans a new plant at Sacramento, to cost $1,000,000, and the California Co-operative Producers, Inc., Oakland, will build a canning plant on adjoining site, to cost $350,000. The Pacific Lumber Company, Scotia, Calif., plans a pulp and paper mill, to cost $500,000. The Pacific Power & Light Company, Portland, Ore., will extend transmission lines in the Lewiston-Clarkston and Idaho district, to cost $90,000. Santa Barbara, Salinas, Calif., and Santa Paula, Calif., plan ornamental lighting systems.

## *Power Company Buying Active in St. Louis District*

All manufacturers in the St. Louis district report the demand for small industrial motors and equipment above normal. One lot of $1,000 worth of motors was shipped to the lead district, another lot of 21 small motors was sold to a refining company for $2,000. A large power company is making extensive changes in its power plants at a cost estimated at over $1,250,000. Orders have already been placed for more than one-half of the needed equipment. Construction projects are as follows:

The Arkansas Portland Cement Company, operated by the Oklahoma Portland Cement Company, Ada, Okla., plans a new mill near Schaal, Ark., to cost $1,000,000. The Century Electric Company, St. Louis, Mo., plans a new plant unit to cost $200,000. The Benton County Utilities Corporation, Gentry, Ark., plans transmission lines at Springtown, Ark. The Southwestern Light & Power Company, Oklahoma City, Okla., plans a transmission line from Comanche to Addington, Okla. The Southwestern Light & Power Company, Oklahoma City, Okla., has acquired the municipal power plant at Eric, Okla. The West Texas Utilities Company, Abilene, Tex., plans a transmission line to Eden, Tex. The Texas Gulf Power Company has acquired the municipal power plant at Strawn, Tex.

## *Slight Increase Noted in Middle West*

There has been a slight increase in the volume of business transacted in the Middle West and the employment situation has improved a trifle. The steel, automobile and electrical industries apparently are operating with a substantial volume of business. Industrial activity is somewhat spotty. An interesting report made public this week of the location of the Wireless Dry Cells, Ltd., an Eastern dry cell manufacturer, in the Chicago clearing industrial district, states that this firm will give employment to 400 to 500 workers and is the 87th firm to locate in this district and the fifth firm this year.

The various utility companies are proceeding with spring construction work and a considerable amount of apparatus purchasing is reported. Among the interesting orders placed this week were one for a 40,000-kw. frequency changer, valued at $350,000, and two others for labor and material to construct a substation, at a cost of $145,000. Jobbers' sales continue to show improvement. Motor sales have increased somewhat and considerable building business is being obtained. Construction projects are as follows:

The Midwest Rubber Reclaiming Company, Monsanto, Ill., plans a one-story plant to cost $150,000. The Northwestern Light & Power Company, Cedar Rapids, Iowa, plans improvements in power plant at Peterson, Iowa, to cost $65,000. The General Motors Corporation, Detroit, plans a seven-story research laboratory to cost $250,000. The AC Spark Plug Company, Flint, Mich., will build a three-story addition, to cost $100,000. The Michigan School for the Blind, Lansing, Mich., plans a new power plant to cost $100,000. The Monroe Auto Equipment Company, Monroe, Mich., plans a factory addition to cost $150,000.

The Firestone Tire & Rubber Company, Akron, Ohio, plans a two-story factory branch plant at Columbus, Ohio, to cost $125,000. The Standard Electric Stove Company, Toledo, Ohio, plans a new plant, to cost $150,000. The Carnegie Steel Company plans an addition to its McDonald mill, Youngstown, Ohio, to cost $1,000,000. The Wisconsin Power & Light Company, Madison, Wis., plans rebuilding of power dam and hydro-electric power plant at Necedah, Wis. The Lake Superior District Power Company, Ironwood, Mich., has secured a franchise for a transmission line from Wakefield to Thomaston. The Dayton Power & Light Company, Dayton, Ohio, plans transmission lines in Piqua, Ohio, and Covington, Ky., districts, to cost more than $500,000; also plant improvements and extensions at Dayton. The Lake Superior District Power Company, Ashland, Wis., plans a transmission line from its White River plant to Mason and Benoit, Wis. Elgin, Ill., and Benton, Wis., plan ornamental lighting systems.

# Activities of the Trade

## Westinghouse Gets Large Power Equipment Order

The Duke Power Company, Charlotte, N. C., has awarded a contract to the Westinghouse Electric & Manufacturing Company for two 60,000-kw. steam turbo-generator units for the Riverbend power plant. The contract involves more than $1,250,000. The first unit of the equipment will be delivered April 1, 1929, and the second on May 1, 1929. The Riverbend steam plant of the Duke Power Company, preliminary work on which is already under way, is occupying a site on the Catawba River, 12 miles from Charlotte. A possible eventual installation of 450,000 kw. in this plant is announced.

---

The Oliver Iron & Steel Company, Pittsburgh, announces that Bertram Quarrie has been elected president of the company to succeed Henry Oliver, who has resigned. Mr. Quarrie was formerly connected with the American Steel & Wire Company and the Otis Steel Company at Cleveland.

The C. O. Bartlett & Snow Company, Cleveland, manufacturer of material handling equipment, announces the appointment of W. H. Norrington as its representative in New York City and vicinity with headquarters at 30 Church Street.

The J. Leo Scanlon Company, Buffalo, N. Y., manufacturers' agent, announces that Vincent J. Brown is now associated with the company as a sales representative.

The Dampney Company of America, Hyde Park, Boston, announces that the sale of its "Apexior" protective coatings for power plant equipment will be handled in southern Minnesota by the Kent Engineering Company, 732 Builders Exchange, Minneapolis, Minn.

The Edison Electric Appliance Company, Inc., 5600 West Taylor Street, Chicago, announces a reduced price on its "Hotpoint" model R 6-lb. laundry iron. Price reductions also have been announced on other standard "Hotpoint" irons.

The Ideal Commutator Dresser Company, Sycamore, Ill., announces the appointment of the Syracuse Supply Company, 314 West Fayette Street, Syracuse, N. Y., as its sales representative for the sale of Ideal commutator resurfacers and other maintenance equipment in the Syracuse territory.

The Federal Gauge Company, 564 West Adams Street, Chicago, announces the organization of the Mercoid Corporation to become the operating unit of the company. The Federal company also controls the Mercoid Corporation and the Arcless Contact Company, a controlling interest in which has just been acquired. General offices will be maintained at and correspondence for any of these three companies should be addressed to 564 West Adams Street, Chicago.

Edwards & Company, Inc., 140th and Exterior Streets, New York City, manufacturer of electric signaling devices, announces several additions and changes to its line of electric signaling devices. The company also has appointed Walter I. Ferguson & Company as representative in Kansas City, 208 Baltimore Building, and in St. Louis, 1486 Arcade Building.

The National Flue Cleaner Company, Groveville, N. J., manufacturer of soot blowers for fire tube boilers, announces the appointment of the Naylor-Hickey Corporation, 643 Washington Boulevard, Chicago, as its Chicago representative and the Furnace Improvement Company, 511 Westminster Street, Providence, R. I., as its New England representative.

The Benjamin Electric Manufacturing Company, 120 South Sangamon Street, Chicago, has placed on the market a gymnasium fixture consisting of a heavy gage steel canopy and wire guard and RLM standard dome reflector, a ball fixture aligner and an intensifier, a supplementary lighting unit for special operations, where in addition to good general illumination it is desirable to concentrate an intense light on certain small areas.

The American Brown Boveri Electric Corporation, Camden, N. J., has received an order from Anderson, Ind., for a 10,000-kw. steam turbine for the municipal power plant.

The Belden Manufacturing Company, Chicago, manufacturer of insulated wires and cables, plans a second unit for its plant at Richmond, Ind.

The Simplex Wire & Cable Company, Cambridge, Mass., has awarded a contract to Stone & Webster, Inc., Boston, for a one-story addition to its plant on Franklin Street.

The Eureka Vacuum Cleaner Company, Detroit, announces a new model 11 Eureka combination home and automobile cleaner with detachable handle.

The Westinghouse Electric & Manufacturing Company has appointed the Times Appliance Company, Inc., 33 West 60th Street, New York City, and 166 Atlantic Avenue, Brooklyn, N. Y., as its agent jobber in the Metropolitan district exclusive of New Jersey. This company, of which E. B. Ingraham is general manager, has been for seven years a special jobber for the Westinghouse company. The officers are E. A. Allen, president; B. A. Allen, vice-president, and E. B. Ingraham, secretary and treasurer.

## General Electric Orders Increase 3 per Cent

Orders received by the General Electric Company for the first three months of this year amounted to $79,925,840, President Gerard Swope has announced. This compares with $77,550,581 for the corresponding quarter in 1927, an increase of 3 per cent, and with $86,433,658 for the first quarter of 1926.

---

The Trumbull-Vanderpoel Electric Manufacturing Company, Bantam, Conn., manufacturer of safety switches, etc., announces the opening of a new office in Boston in charge of Frank W. Garner, who has been connected with the New England sales force of the company.

The Rockbestos Products Corporation, New Haven, Conn., manufacturer of asbestos covered wires and cables, announces the appointment of C. Dent Slaughter as its Pacific Coast representative, with offices at 314 Twelfth Street, San Francisco; 324 North San Pedro Street, Los Angeles; 200 North Thirteenth Street, Portland, and 1108 Post Street, Seattle.

C. Wendel Muench & Company, 557 West Monroe Street, Chicago, has been organized to serve electrical manufacturers as advertising agents. The organization will specialize in electrical accounts, rendering merchandising direct-by-mail and general advertising service. C. W. Muench, for nine years director of the sales and advertising of George Richards & Company, manufacturers of "Hemco" products, is head of the new organization.

The W. N. Matthews Corporation, St. Louis, manufacturer of electrical specialties and mechanical painting equipment, has added the No. 6 "Xpandix" anchor to its line. This new unit is a two-way expanding type of malleable anchor recommended for 6,000 lb. maximum strain.

The Buffalo Foundry & Machine Company, Buffalo, N. Y., has acquired the assets, physical properties and patents of the Chemical & Vacuum Machinery Company and will supplement its "Buflovak" and Buflokast" lines of driers and evaporators with several new types. Charles O. Lavett, former general manager, and H. E. Neubauer, former chief engineer of the Chemical & Vacuum Machinery Company, are now associated with the Buffalo Foundry & Machine Company.

Copeland Products, Inc., Detroit, manufacturer of electric refrigerators, reports the largest first quarter's shipments in the company's history, with an increase of 45 per cent over the first quarter of 1927.

The R. Thomas & Sons Company, East Liverpool, Ohio, manufacturer of porcelain insulators, announces that after May 1 its executive offices will be located at Lisbon, Ohio.

# New Equipment Available

## Manual A.C. Starter

A manual across the line alternating-current motor starter, the CH-9115, is announced by the Cutler-Hammer Manufacturing Company, Milwaukee. Designed to meet the need for an inexpensive manual starter, it includes overload cutouts giving complete motor protection, cadmium plated, double break, roller type contacts and small size, safety, dustproof inclosing case. The roller type contacts are of the double break type, cadmium plated, and by breaking the arc in two places give several times the life of ordinary contacts. In addition, the contact rollers turn after each operation to present a new contact surface for the next operation.

Complete motor protection is obtained during both the starting and running periods. The thermal overload cutouts provide the necessary time interval to take care of starting inrushes without shutting down the motor. The starter is small and compact, the inclosing case is dustproof and the cover is in two parts. This permits opening the lower section only for replacing fusible links in the thermal overload cutouts. The cover can be opened only when the starter is in the "off" position and all current-carrying parts are dead. Installation can be made without removing the panel from the case. All parts are easily accessible for quick inspection.

## Portable Farm Motor

A line of farm "Handi-Motors" consisting of the Wagner air-jacketed (totally inclosed self-ventilated) motor mounted on a portable hand truck has been placed on the market by the Wagner Electric Corporation, St. Louis. Where the air-jacketed motor is not required the regular Wagner open type sleeve motor is supplied. Motors of 2, 3, 5 and 7½ hp., 1,725 r.p.m., 220 volts, single or polyphase are used. The same truck is used for any motor in the line.

Pedestal Type Traffic Signal.—A pedestal type traffic signal using lights in groups of three each on all four sides, and designed to stand in the center of street intersections, or for mounting on curbs is being marketed by the General Electric Company The new signal differs principally from previous types in the design of the base and the length of the overhead fitting. The new type incorporates a form for the concrete as part of its base, not only saving the time and labor of making a form but also making the signal and base an integral unit and therefore less liable to breakage. The signal may also be obtained in an adjustable form for use at street intersections where the angle of intersection is other than 90 deg. In the adjustable form the signal faces are so arranged that they can be moved to any position, either greater or less than a right angle.

## Power Supervisory System

The type E Strowger power supervisory system has been developed by the Electric Power Equipment Corporation, Philadelphia, to meet the needs of comparatively small power installations for a simple method of control and supervision from a distant point. It is said to be particularly suitable where continuous indication is not necessary and where high speed of operation is not important.

The equipment at the substation consists essentially of a switch of the standard Strowger type having a number of semi-circular rows of contacts arranged parallel with each other and in horizontal planes. Associated with each row of contacts is a finger attached to the switch shaft. The shaft and fingers are capable of being moved together, step by step, by means of a magnet, to any desired set of contacts, and may be released from any point by a release magnet which brings the shaft and fingers back to the "home" position. The contact fingers on the switch are of the short-circuiting type, avoiding the use of flexible cords. Each set of contacts is associated with a circuit breaker or other unit to be controlled. The selection of a particular unit by the switch is controlled by the circuit selector at the dispatcher's station.

*Dispatcher's control cabinet for power supervisory system*

At the substation there is a polarized relay which may be operated in one direction or the other by means of a control key. A number of resistances in the control circuit are so adjusted as to afford a different deflection of the dispatcher's voltmeter indicator. The dispatcher's control cabinet is shown in the illustration. A standard 45-volt dry battery unit supplies current for operating the voltmeter, a 24-volt storage battery is required for operating the switch and relays and a 110-volt alternating-current circuit is used for ringing the alarm. If a unit trips out automatically the alarm will ring. The dispatcher can then check to determine which unit or units have tripped out, when they may be reclosed in the usual manner by the operation of the control key.

## Motors for Gaseous Mines

Direct-current motors with starting switches, designed to meet the requirements of the U. S. Bureau of Mines for equipment permissible for use in gaseous mines, have been developed by the General Electric Company and are offered in 1, 3 and 5-hp. ratings. These equipments are for use on mine pumps, room conveyors and for similar applications where constant-speed, direct-current motors are suitable. These motors and starters, when included in an assembly of elements submitted for approval to the Bureau of Mines, will not themselves need to be tested in an explosive mixture, since they have already met the requirements of such test; but the approval plate can be applied only when the whole assembly has been approved, which is in accordance with the bureau's established practice. The new equipment has been give the General Electric designation "Class BM."

## Across-the-Line Motor

A line of squirrel cage motors from 1 hp. to 30 hp. for control by an automatic push-button system has been developed by the Triumph Electric Corporation, Cincinnati. These motors are designed to develop at least 150 per cent of the full-load torque at starting, when connected directly across the line. There is no compensator or resistance type starter used, and the current taken is below the limits set by the N.E.L.A. regulations. The motors are fitted with Timken roller bearings, but can be supplied with either ball or sleeve bearings if desired.

Primary Cutouts.—A new line of inclosed expulsion type cutouts has been designed by the General Electric Company. The new cutouts are said to have very high dielectric strength, both for 60-cycle and impulse voltages. Current ratings and interrupting capacity ratings have been increased over those of previous designs. The line comprises four cutouts, rated as follows: 60 amp., 2,500/4,000Y volts; 60 amp., 7,500 volts; 150 amp., 5,000 volts, and 150 amp., 7,500/12,500Y volts. The company states that the 60-amp. cutout can economically replace plug type cutouts generally used on 2,300/4,000Y volt systems. The wet-process porcelain housings used are of a new design. The doors are of "Textolite," a molded insulating compound, with handles of the same material, and they may be opened by a pull of a standard switch hook. The fuse holder is supported by the door and is removed from the circuit when the door is opened.

# Electrical Patents

*Announced by U. S. Patent Office*

(Issued April 3, 1928)

Reissue 16,920. Burglar-Proof Induction Coil; H. J. Murray, New York, N. Y. App. filed Oct. 11, 1921.

1,664,403. Circuit-Continuing Device; H. A. Douglas, Bronson, Mich. App. filed April 17, 1922. For a headlighting or other reflecting lamp.

1,664,408. Attachment Plug; F. F. Frakes, Columbia, Tenn. App. filed May 31, 1927. Having a fuse of the removable type in circuit with the plug, and secured therein.

1,664,429. Electric Paint Remover; W. Multhaup, Winona, Minn. App. filed March 29, 1927.

1,664,457. Electrical Hair or Massage Brush; A. Lloyd, London, England. App. filed April 10, 1926.

1,664,519. Automatic Regulation in Electric-Lighting Systems; F. C. Lyne, Westminster, London, and J. Etchells, Aston, Birmingham, England. App. filed April 25, 1927. As train lighting systems.

1,664,534. Circuit Controller; F. D. Zimmerman and E. M. Pyle, Jerome, Pa. App. filed May 26, 1926. Manually operable electric motor starters and controllers.

1,664,540. Dynamo Frame; W. A. Chryst, Dayton, Ohio. App. filed Aug. 27, 1925. For small machines as are used on automobiles.

1,664,561. Short-Circuiting Mechanism; J. J. Janca, St. Louis, Mo. App. filed Dec. 24, 1925. For single phase motors.

1,664,584. Electric Cooking and Heating Apparatus; J. H. Williams, Toronto, Ont., Can. App. filed April 6, 1925. For use in apartments or rooms where the usual cooking and heating facilities are not readily available; fireless cooker type.

1,664,586. Switching Apparatus; L. T. Barnes, Hempstead, N. Y. App. filed Dec. 5, 1925. Applicable to flashing lamps or the like.

1,664,624. Electric-Fixture Mount; M. Heichen, Brooklyn, N. Y. App. filed July 24, 1926. Combined switch and mounting for side wall fixtures.

1,664,672, 1,664,673. Induction Electricity Meter. A. L. Emens, Lafayette, Ind. Apps. filed March 12 and Dec. 24, 1926. Having a protecting outer case.

1,664,686. Junction Fitting for Metallic Armored Electrical Conductors; J. H. Hunter, Detroit, Mich. App. filed April 13, 1925.

1,664,692. Coupling for Battery Terminals; F. W. Leuthesser, Oak Park, Ill. App. filed March 7, 1925.

1,664,708. Brush for Generators, Etc.; A. A. Schupp, Saginaw, Mich. App. filed April 2, 1924. Made of a cast metal alloy consisting of metallic lead and metallic copper in substantially equal proportions.

1,664,720. Thermo Electric Generator; C. W. Woodruff, Columbus, Ohio. App. filed Dec. 7, 1925. Thermo-electric cell of the type employing hot and cold junctions of dissimilar metals for supplying filament and plate currents in vacuum tube circuits.

1,664,750. Process for the Production of Galvanic Metal Coatings; F. Kirschner, Vienna, Austria. App. filed Oct. 12, 1923.

1,664,758. Electrically Heated Sadiron Stand; R. O. Reynolds, Auburn, Me. App. filed Nov. 26, 1926.

1,664,759. Electric Fitting and the Like; A. B. Rypinski, Brooklyn, N. Y. App. filed May 13, 1921. Mountings of sockets on a base of porcelain or non-conducting material.

1,664,778. Thermostat; L. P. Hynes, Albany, N. Y. App. filed March 24, 1923. As used on railway cars to control the heating.

1,664,781. Dynamo-Electric Machine; G. H. Leland, Dayton, Ohio. App. filed Nov. 22, 1920. Single-phase alternating current motors of the repulsion-starting and induction-running type.

1,664,800. Electrochemical Method of and Means for Protecting Buried Pipe Lines Against Corrosion; R. Van A. Mills, Sandy Spring, Md. App. filed Dec. 5, 1924.

1,664,845. Switching Device; A. P. Ball, Detroit, Mich. App. filed Nov. 23, 1921. Having means which insure that the movable switch contacts will be completely engaged with the stationary contacts upon a closing movement of a switch operating handle or analagous device.

1,664,857. Cigarette Lighter; M. J. Harkless, Homewood, Ill. App. filed Sept. 13, 1926.

1,664,882. Metal-Casting Machine; W. S. Hadaway, Jr., New Rochelle, N. Y. App. filed Sept. 6, 1921. Heaters for metal molding machines, such as those used for casting type.

1,664,947. Traffic Regulator; M. E. Rusch, St. Paul, Minn. App. filed Nov. 13, 1925.

1,664,952. Signaling Apparatus; N. H. Suren, Needham, Mass. App. filed Sept. 6, 1924. Non-interference signal transmitter for use in signaling systems which are normally conditioned for metallic circuit operation and have provision for operation through a normally open ground return in the event of a broken metallic circuit.

1,664,986. Plug Connecter; B. P. McKinley, Flushing, N. Y. App. filed Dec. 8, 1923. Twin type.

1,664,992. Electrotherapeutical Apparatus; S. Pongo, New York, N. Y. App. filed July 26, 1927. Electric bath-cabinet.

1,665,014. Thermostatic Current Control; O. Q. Beckworth, Los Angeles, Calif. App. filed July 9, 1925.

1,665,018. Electric Swivel Socket; P. S. Black, Fort Worth, Tex. App. filed April 25, 1927.

1,665,021. Automatic Electric Switch for Cable-Carrying Drums; J. H. Cohen, Bridgeport, Conn. App. filed Nov. 3, 1923.

1,665,038. Electric Welding Machine; J. W. Meadowcroft, Philadelphia, Pa. App. filed Dec. 7, 1925. Spot welder with work-handling mechanism adapted for use where the parts or assemblies to be welded are relatively large and cumbersome, such as the door and body sills in the building of sheet steel automobile bodies.

1,665,048. Battery Terminal; A. W. Weimer and J. F. Smith, Geneseo, Ill. App. filed Jan. 3, 1927.

1,665,060. Automatic Control Means for Electromagnetic Operating Devices; H. K. Hitchcock, Pittsburgh, Pa. App. filed Feb. 5, 1927.

1,665,062. Mold for Making Metal Patterns by Electrodeposition; A K. Laukel, Detroit, Mich. App. filed Oct. 15, 1926.

1,665,066, 1,665,067. Electric Welding Machine; J. W. Meadowcroft, Philadelphia, Pa. Apps. filed Nov. 24, 1925 and March 7, 1927. For spot welding.

1,665,095. Eectrical Plug Lock; J. B. Henry, Connersville, Ind. App. filed Jan. 5, 1927.

1,665,113. Circuit Breaker; F. W. Roller, East Orange, N. J. App. filed Sept. 24, 1924. Automatic air circuit breaker.

1,665,122. Tractor-Lighting Device; W. H. White, Copeland, Kan. App. filed June 25, 1927. Means for attaching a magneto to tractor so that it will be driven from the pulley shaft of the tractor to furnish current for a lighting system placed on the tractor.

1,665,126. Safety Switchboard; J. F. Burns, Philadelphia, Pa. App. filed June 23, 1922.

1,665,166. Electrical Connecter; J. E. Graham, London, England. App. filed Oct. 21, 1925.

1,665,169. Holder for Electric Fuses; O. E. Holtsclaw, Elwood, Ind. App. filed April 21, 1925. To hold a fuse perfectly tight without the aid of springs.

1,665,191. High-Tension Cable to Prevent a Breaking Down of the Insulation; E. G. Sievert and H. Svenson, Sundbyberg, near Stockholm, Sweden. App. filed Nov. 9, 1925.

# New Trade Literature

ASBESTOS INSULATED WIRES AND CABLES.—The Rockbestos Products Corporation, New Haven, Conn., has issued two bulletins covering the Rockbestos "A.V.C." (asbestos and varnished cambric) cables. The bulletins give complete construction specification tables for this insulation, which is intended for the utmost in severe conditions of heat, moisture, acid fumes, oil, flame and gas. Another bulletin issued by the company contains the standard specification of all Rockbestos insulated wires and cables as to the quality of the copper, the asbestos and the method of impregnating, testing and inspecting. A new asbestos and varnished cambric insulated switchboard wire is described in the bulletin covering switchboard wires and cables.

TRANSFORMERS.—The Packard Electric Company, Warren, Ohio, has issued pamphlets Nos. 529, 521 and 517 describing and illustrating its type LD dry-type current transformers, type BK1, BK2 and BK3 indoor dry-type current transformers and its type PW outdoor potential transformers.

TRANSMISSION AND DISTRIBUTION MATERIAL.—Porter & Ross, Inc., 30 Church Street, New York City, has issued a 240-page illustrated catalog as a source of pole line material buying information. The catalog contains a good deal of material covering poles and includes specifications, information for storing and painting poles, and a table of sizes and carloadings. A chapter is devoted to outdoor substation equipment covering a line of disconnecting switches, bus supports, straight connectors, etc. A line of construction tools are also described and illustrated.

ELECTRICAL AIR HEATERS.—A catalog issued by the Edison Electric Appliance Company, Inc., 5600 West Taylor Street, Chicago, describes the "Hotpoint" electric air heaters for the home. The catalog is well illustrated and a chapter is devoted to the essentials of correct room heating. The "Calrod" heating unit used in "Hotpoint" heaters is illustrated and described. The catalog contains information as to how to determine heater sizes, how to estimate heating costs, and other miscellaneous data on heating.

AIR PREHEATER.—Catalog AH-3 issued by the Combustion Engineering Corporation, 200 Madison Avenue, New York City, describes and illustrates the "C-E" air preheater. It contains charts showing typical performances of the air preheater and drawings show the applications of the air preheater to different installations.

MOTOR-GENERATOR SETS.—Bulletin No. 450 issued by Roth Brothers & Company, 1400 West Adams Street, Chicago, describes and illustrates its motor-generator sets, including the new two-bearing motor-generator sets recently developed by the company. General specifications covering the line are included. Tables give a complete listing of the various sizes in the different lines.

# Foreign Trade Opportunities

Following are listed opportunities to enter foreign markets. Where the item is numbered, further information can be obtained from the Bureau of Foreign and Domestic Commerce, Washington, by mentioning the number:

An agency is desired in Rosario, Argentina (No. 30,667), for storage and radio batteries.

Purchase is desired in Temuco, Chile (No. 30,665), of batteries and flash lights.

Purchase is desired in Baghdad, Iraq (No. 30,696), of electric automobile bulbs.

Purchase is desired in Durango, Mexico (Nos. 30,674 and 30,675), of electric corn poppers and electric ice cream freezing machines.

An agency is desired in Manila, P. I. (No. 30,669), for electrical goods.

An agency is desired in Rome, Italy (No. 30,668), for household electrical machines, especially refrigerators and washing machines.

An agency is desired in Warsaw, Poland (No. 30,666), for farm lighting plants.

An agency is desired in Paris, France (No. 30,643), for air compressors.

Purchase is desired in Naples, Italy (No. 30,641), of hand-operated floor-scraping (parquet) machines.

Remarkable building progress has been made in the principal South African municipalities and many projects are contemplated.

A power company has filed plans with the Canadian Department of Public Works at Ottawa for a hydro-electric development on the Ottawa River, to cost $2,500,000. The property now held by the company is in virtue of a water lease from the Province of Quebec. (Canada No. 274,191.)

# Business Facts for Electrical Men

Selected Statistics Presented Graphically for
the Use of All Interested in Analyzing the
Trend of the Electrical Business

## The Assistant Tax Collector

OF EVERY dollar paid by the public for electric light and power, 10 cents is used for taxes. The electric service company is one of the assistant tax collectors, and a big one, for our various political subdivisions.

The percentage of the public's dollar which it has to pass on differs among the several states, ranging, among the states for which information is available, from 6.7 per cent in Alabama to 13.5 per cent in South Carolina. The average rate is about 9.7 per cent.

On the basis of data taken from public utility commission reports or obtained at commission offices it has been possible to analyze the operations in twenty states and the District of Columbia. Although this is fewer than half the number, the operations account for $1,026,163,241 of the operating revenue for 1926, constituting about 62 per cent of the national total. The taxes paid by the companies earning this revenue amounted to almost $100,000,000, or, to be precise, $99,303,840. Assuming that the same ratio holds in the remaining states, the electric light and power companies of the United States paid, in 1926, about $160,000,000 in taxes.

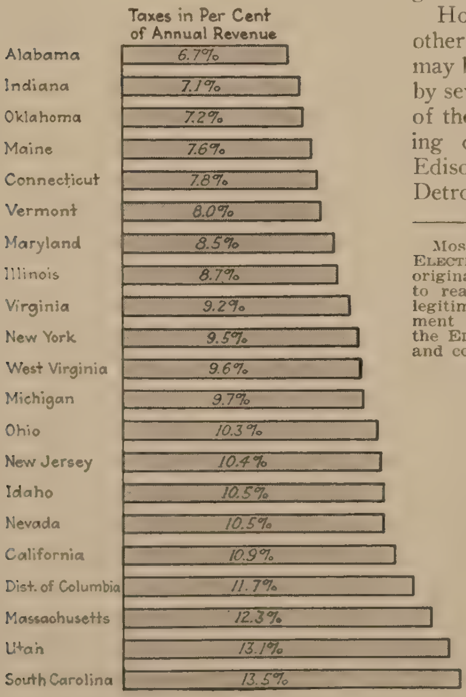
Data were also obtained for one additional state, Kansas, but they unfortunately did not include operations of companies serving only one city or town each. To what extent that omission may affect the ratios is not known, but it is not believed to be great. The state figures as reported indicate a tax ratio of about 5 per cent, which is lower than that for Alabama and is, in fact, the lowest figure received. If this truly represents the situation it is then proper to include the Kansas figures with the others; the effect is to change the general average to 9.6 per cent. The effect on the estimated national total of $160,000,000 for taxes is negligible.

How this sum compares with the other expenditures of the industry may be judged from figures published by several individual companies. Two of them are shown in the accompanying diagram: The Commonwealth Edison Company for 1925 and the Detroit Edison Company for 1926. Their proportion for taxes corresponds fairly well with the national average, and the allocation of costs may be regarded as typical. It will be seen that the taxes are roughly equal to the interest charges on the funded debt; they are from half to two-thirds as great as the cost of fuel; they are about half as large as the biggest item, that for labor.

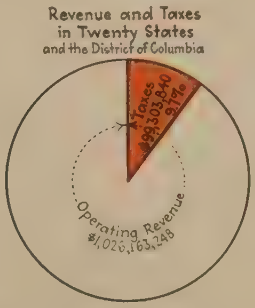
Attempts to draw deductions regarding localities or types of plant associated with high or low tax ratios lead to inconclusive results. Alabama and South Carolina are both Southern states. One is at the top of the column, the other at the bottom. In New England Maine, Connecticut and Vermont are near one end of the list and Massachusetts near the other. Waterpower states like Alabama, Maine and California are not distinguishable, by position in the table, from predominantly fuel-using states like Indiana, Oklahoma, New Jersey or Massachusetts.

The circumstance that taxation is usually based primarily on property values rather than on revenue is of especial significance to electric power companies, where, in round numbers, an investment of five dollars is required to bring in a dollar of revenue. The effect is to make the ratio of taxes to earnings much higher than in industries or other business activities having a more rapid turn-over.

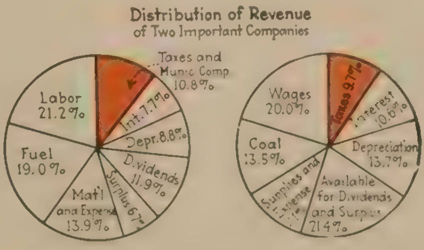
Electric service carries a very sizable indirect tax. This expense becomes part of the production cost. It cannot be taken out of any of the other items.



*One dollar in seven for taxes*



*Taxes absorbed 9.7 per cent*



*Taxes equal half the labor cost*

# West Reports Increased Activity During First Quarter

THAT the manufacturing plants of the Western States witnessed slightly increased productivity during the first quarter over that reported for the same period in 1927 is indicated by reports received on monthly electrical energy consumption by some 400 large manufacturing plants operating in this section. The increased average rate of productivity during the quarter was 2.2 per cent over the first quarter of last year. The year opened with the rate of activity slightly under that of January last year, but both February and March witnessed a rate of activity over that of the same months last year, the March activity being about 10.4 per cent over March of 1927, but slightly below March of 1926. Past history indicated that a drop in the rate of activity in manufacturing plants was normally to be expected in March, and the current March followed this general trend by reporting a drop of 5.3 per cent under February. This was slightly under the drop witnessed by general industry in the nation as a whole.

Every industrial group operating in the Western States reported a rate of operations during March under that of February, after correction is made for the number of working days. On the other hand, every industrial group, except the metal industries group and the shipbuilding industry, reported March operations over those of March last year. Three of the industrial group—chemicals and allied products, metal industries group and shipbuilding—reported an average rate of operations during the first quarter of the current year under that of the same period last year.

*Indexes of Productive Activity in the Western States*

All Figures Adjusted for Number of Working Days

| | March, 1928 | February, 1928 | March, 1927 | Average for First Quarter 1928 | Average for First Quarter 1927 |
|---|---|---|---|---|---|
| All industry | 110.4 | 116.7 | 100.1 | 114.0 | 111.6 |
| Chemicals and allied products | 104.6 | 106.9 | 85.8 | 104.8 | 109.5 |
| Food and kindred products | 101.8 | 104.8 | 83.8 | 106.8 | 92.5 |
| Lumber and its products | 122.0 | 124.2 | 91.1 | 121.8 | 105.3 |
| Metal industries group | 113.3 | 123.0 | 130.7 | 123.4 | 136.8 |
| Paper and pulp | 131.2 | 139.7 | 118.7 | 135.7 | 129.5 |
| Rubber | 153.6 | 159.8 | ..... | 151.2 | ..... |
| Shipbuilding | 84.7 | 100.5 | 117.7 | 93.8 | 123.5 |
| Stone, clay and glass | 139.4 | 170.8 | ..... | 153.4 | ..... |

## *Politics and Engineering*

THE big tasks before Congress remain unfinished while the politicians spar for position in the presidential primary ring. Boulder Dam, Mississippi flood control and Muscle Shoals afford opportunities for the introduction of bills whose contents are designed to appeal to public sentiment. These projects are the excuses for congressional orations in which the orator defends the public from predatory interests with many mighty words. This is a typical presidential year.

Engineering and economic considerations should dictate legislation on Boulder Dam, flood control and Muscle Shoals. Engineering and economic facts should be established before money is spent or policies determined. The American Engineering Council has stated that Boulder Dam and flood control should be subjected to more thorough engineering investigation before legislation is enacted. A very able committee of the council reported only last week that the Boulder Dam project is not based on sufficient engineering data to establish its cost or its feasibility. Despite engineers and their reports, however, Congress is only too likely to discuss these projects with an eye to popular appeal and to enact legislation upon them which reflects political ambitions and not engineering data.

* * * *

## *A Good Investment in Managerial Time*

NOT a few public utility managers regard attendance upon rate hearings as an unwarranted burden upon their normal activities. Such executives apparently believe in shifting the load to the shoulders of legal counsel whenever possible and confine their own participation to directing the preparation of cases. Granted that more than half the time spent in a hearing room is extremely irksome to an alert and energetic manager and that reliance upon the legal profession is essential to proper procedure, the fact remains that appearance before a public regulating body almost always carries within itself potential opportunities of the greatest value from the standpoint of public relations.

Press representatives at hearings listen closely to the utterances of executives, and the words of a straightforward, businesslike official daily concerned with the operation of a utility bear weight with commissioners and often reach front-page display space in local news sheets. Seldom indeed does a rate case terminate without an opportunity for a qualified executive to tell the story of the utility's aims and achievements to the people via the hearing room, and while constant attendance on protracted hearings is not essential unless the situation is critical, "absent treatment" is a risky proceeding. It should never be forgotten that the public is virtually always in favor of hearings, regardless of the subject matter, and to fail to capitalize these opportunities is to fall short of demonstrating the truth that the company has nothing to conceal but instead everything to reveal.

* * * *

## *Diversity Stabilizes Utility Investments*

FROM the smallest central station serving a few score of customers in an isolated area to the investment group with far-flung properties half a continent or more apart, diversity underlies the operations and prosperity of all. The use of energy by customers supplied by a single-phase feeder illustrates the value of non-coincident demands on a little system serving a thinly settled rural region many miles away from another which provides power in blocks for densely grouped industries over cable trunk lines forming an interconnected set-up of great economic importance. Diversity is common to both. Go back to the immigrant's "lean-to" equipped with but two lamps and carry the element of diversified usage up the line to a completely electrified steel mill or railroad zone entering a metropolitan area. Non-coincident use of service is at the bottom of the capital outlay required to meet the needs of these customers without excessive cost. Upon the ability of the engineer to gage the relation between demand and plant investment required to render such service depends no small part of the success of the enterprise.

If the investor could trace the part which diversity plays in stabilizing the light and power business, he would be both amazed and brain-weary. The complex variations in usage of energy which are finally integrated into the plant or system load curve exhibit extraordinary differences in time and magnitude when analyzed even superficially with the aid of technical imagination. The transformation of these usage differentials into a total output burden which is finally equated into revenue from a system or group of systems marks a process of almost impregnable economic strength. The universality of electric service does not restrict its success in systems serving many customers of the same type unless expansion has run wild from the standpoint of capital outlays. Witness the high diversity factor of the electric range load in a single large apartment house. It is true that volume business must accompany diversity for economic success, and suitable rates are likewise basic. But those who market securities of light and power companies and those who buy them do well to reflect from time to time upon what diversity of demand and usage produces in the way of stability of earning power. Given sound management—and by this is meant not brilliance of administration but good, thoroughgoing, competent direction of loyal and intelligent employee service—diversity will do its stabilizing work in the face of practically every obstacle except political interference; and with right public relations it is hardly too much to say that nothing but a cataclysm of nature can jeopardize success—and even then but temporarily.

* * * *

## *Why Does a Billion-Dollar Load Go Begging?*

PROFESSEDLY, utility executives are keenly desirous of building industrial load on their lines. The enormous sums of money that have been invested in power plants and systems must show earnings. New loads and more intensive development of present applications for electric service must be sought. But with these conditions existing a potential industrial heating load amounting to millions of kilowatts and more than a billion dollars in annual revenue is virtually going begging so far as effective selling effort on the part of the majority of power companies is concerned. Some few electric utilities have taken definite and effective steps to set up in their sales departments a competent sales engineering staff to develop the heating load. For the most part, however, the central-station companies in their attempts at organizing an industrial heating department have "sent a boy to do a man's job."

Why does this condition exist? The manufacturers of industrial electric heating equipment want and need the sales assistance of the power companies. It is no fault of the utility power sales departments. They are doing the best they can with the equipment and personnel at their command. The real difficulty is executive failure to sense the possibilities of this class of business in load and revenue. The heating load properly developed means a large increase in revenue to the central-station industry. It is revenue not only for one year but for many years to come. Central-station executives would surely, therefore, find it profitable to map out and approve a plan to promote this business which could be followed through by their sales departments. Some electric utilities have already done this. Is it not time for many others to organize to do their share in the actual selling of this class of load?

* * * *

## *Carrier-Current Performance*

THE use of carrier-current telephone systems is accepted; but the degree of acceptance is a variable depending on the kind of experience that has been had. Some operating men feel that the reliability of carrier communication has not been fully demonstrated. Some will state flatly that its complete lack of reliability has been proved to them. Others will admit that it has its deficiencies, but maintain that these deficiencies can be minimized to a point comparable to, or even below, the defects of wire communication and that carrier-current systems are perfectly workable and practicable.

There is a large interconnected system in the South that has grown very rapidly in the past few years. It covers such a large area that a private-wire telephone system would be very costly. A carrier installation was made at a much lower cost and has been used for load dispatching for about four years with perfect satisfaction. As a matter of fact, the assertion is made that the carrier communication is quieter during storms than the long-distance telephone. The experience of this company indicates that carrier communication cannot be satisfactorily maintained over open switches or through transformations. It has been learned that proper maintenance is necessary for satisfactory operation of the system. If the impossible is not expected of it and if it receives reasonable attention, carrier-current communication may be included in the scheme of operating procedure with every anticipation that it will perform acceptably.

Carrier systems are secondary lines of communication in most cases, and more and more it becomes apparent that the Bell system telephone lines should be relied upon for primary communication facilities. It is to be expected that the Bell engineers will develop their facilities to meet power-company requirements and that Bell executives will realize the value of the business available from light and power systems.

## *What Is in the Atom?*

SCIENTISTS are trying to unravel the inner structure of matter. They are using mathematics, physical analogies, chemical reactions, spectra and even lightning in order to find out what matter is made of. They have not found the answer to this problem, but they have found enough facts to cause them to throw about all the past laws and theories into the discard.

Among the first assumptions to be discarded were the old periodic system and the theory of immutability of the elements. Radioactivity did for these, because it gave absolute evidence that one element could transform itself into another. Once it was known that elements were destructible, it became necessary to attack individual atom structures, and now science is in the midst of trying to explain atoms and molecules so that it may have another and correct periodic system and another theory of matter that also is correct. Some progress has been made through the researches of Niels, Bohr, Stoner, Millikan and others, but there is a long, rough road still ahead.

Of interest to electrical engineers is the fact that the attack on the atom is premised on the atom consisting of positive and negative electric charges, and that experimental work consists of attempts to ionize atoms by electrical or chemical means. It is thought that the positive electric charges are bonded to the residual mass of the atom which we call matter, and on this assumption Rutherford developed the modern nucleus theory of matter. Then Van der Broeck, Moseley, Bohr and others readopted the century-old hypothesis of Prout according to which all elements are more or less complex aggregates of the element hydrogen because the hydrogen ion is the unit positive charge. So a new periodic table was set up based on the number of positive charges and negative charges in the atoms, and in this table the negative charges were added to make atomic weights equal atomic numbers. Then planetary laws were applied to the internal structure of the atom, definite mechanical arrangements of internal charges were assumed, and the two emission assumptions necessary to the axioms of the quantum theory of energy were added to give modern atomistics. But a system of mechanics valid for such a system of atom charges is still unknown and the structure of all atoms is still unknown. We know only the structure of the atomic nucleus.

The whole mechanics of atomic theory is now undergoing a crisis, and the elaborate planetary structure and theory of Bohr is challenged. It is questionable whether a mechanical explanation of atomic and interatomic processes is needed, and recent work with the spectra and radioactive forces has developed data that require such a mass of corrective hypotheses to support the theory of mechanics that the whole principle is challenged.

Atomic structure is so bonded to the quantum theory of energy that a simultaneous solution of both must be had. We cannot yet devise an experiment to investigate the changes taking place within the atom. Our experimental tools themselves are atomic structures, and interatomic actions occur which prohibit conclusive experimental results. But the scientists are still undiscouraged, for the goal is very enticing. They should be encouraged in their work, for in it lie infinite possibilities for future engineering applications of value to civilization.

## *The Answer to the Jobber's Problem*

RECENT announcement by the executive committee of the Electrical Supply Jobbers' Association that the managing director appointed last November had withdrawn impresses once more upon electrical men the fact that distribution in this industry is sick and worried. It had been hoped that following a study of the jobber's problem by a fresh mind would come some plan to lead the wholesalers of electrical supplies and equipment out of the embarrassing morass and point the way to prosperity. But it is hardly to be expected that help will come from without nor yet from any effort to restore the good old times. The cure will have to come from within. The plan will have to be fashioned for the future—no matter what the past has been.

Fundamentally the value of the jobber of this industry—to any industry—depends upon the effectiveness of his warehouse and his delivery service. He is not cast in the plot as a creative builder of markets. His function is to collect goods from many sources into a local stock and deliver them in such assortment as the buyer desires. True, household appliances and radio both have been actively promoted by jobbers, but both these lines most fortunately became available in times of stress and were seized upon to save the situation. There will be many jobbers also who will continue to specialize in specialties, but, by and large, the jobber functions best as a distributor of staple lines, and that is where his best success has been made.

The answer to the jobber's problem will in the end be found in three directions probably—through a more accurate knowledge of his markets, through a more expert and economical operation of his warehouse and delivery service, and through more highly organized industry policies. Or it can be put in other words thus: By an intelligent use of complete industry statistics he will eliminate much present waste in buying, selling and in turnover. By a closer analysis of methods he will learn to reduce both his stock inertia and his territory and provide a more economic service. And by stronger industry co-ordination he will overcome some of the weaknesses of his present relations both with the manufacturer and with the power industry, for he will be able then to prove his worth.

No Moses can be expected to come from over the hills to lead the jobbers to a land of plenty. The function of distribution in the electrical industry waits for prosperity upon action by the jobbers themselves individually and as a group.

* * * *

## *Tremendous Trifles*

THE importance of the small and relatively trifling thing has been told and retold—the shoe, the horse, the rider and the kingdom lost for the want of a horseshoe nail. Men, it has been said, stumble not over mountains but over molehills. The big job of the electric light and power industry is well recognized. Continuity of supply, steady voltage and service are symbols of the business. The less tangible matters are in a measure recognized under the title of public relations. Too often this is assumed to be a closed book when a director has been appointed and certain rules have been formulated. Commercial men, presumably, are those who come in contact with the customers most often and have been well trained; but meter readers, testers and inspectors, linemen and truck drivers are in continual association with consumers and the public. How can they aid in the job of fostering good relations with those they meet? How can they strengthen the tremendous trifles?

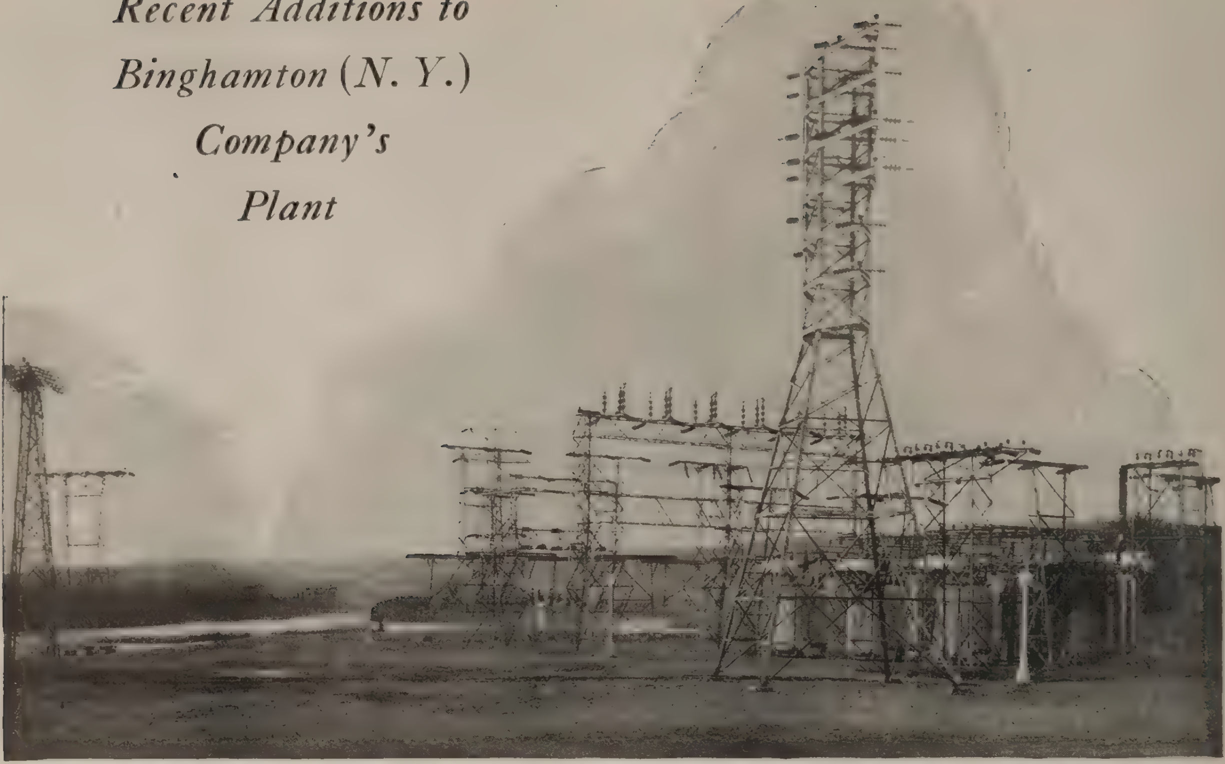
Electric utility men can learn a lesson from department stores, taxicab companies, railroads, up-to-date gasoline filling stations and hotels. Every meterman, every lineman and every employee engaged in similar work might well have a uniform. It should be trim and neat in appearance. It should be adapted to the occupational duties of the wearer and it should be kept in repair and clean condition. A uniform means business. It has an amazing reaction upon the psychology of the employee. If you doubt it, compare rides in taxicabs with uniformed and ununiformed drivers. Apparel often proclaims the—service.

* * * *

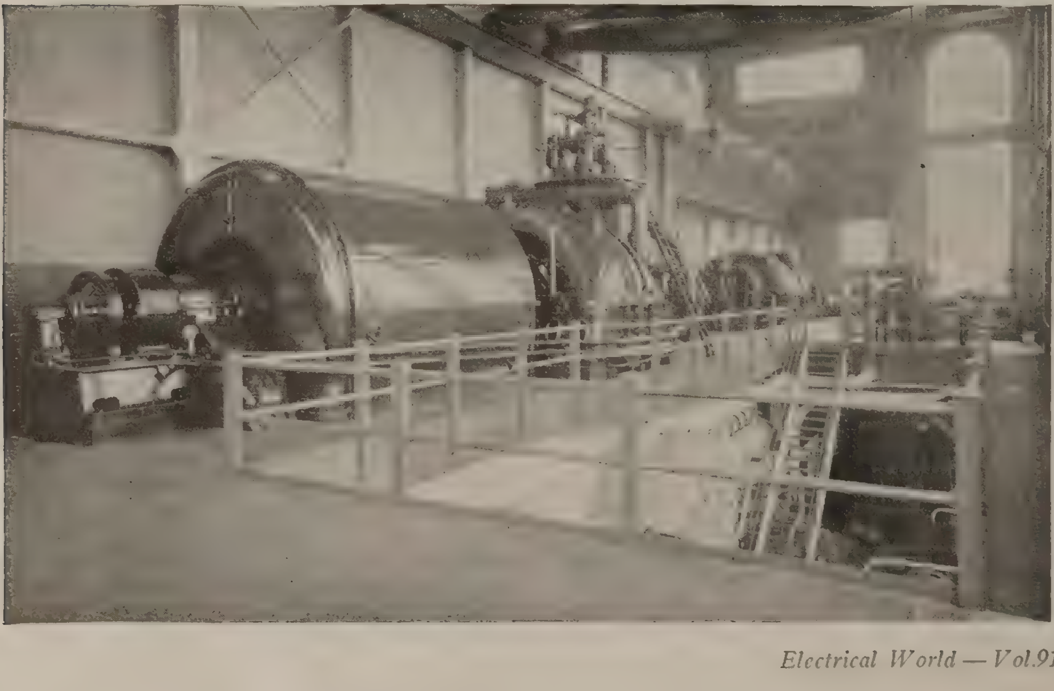
## *When Statistics Would Have Saved the Day*

WHEN sales decline within a short time after a new manufacturer has entered the field the logical conclusion of the older manufactures, if they lack statistics on this situation, is that the new competitor is getting an unusually large share of the business. Often the result is that the older manufacturers reduce prices to meet the situation. An actual case last year resulted in a price reduction amounting to nearly one-third. The price cut in no way helped the situation. Had statistics been available, the manufacturers involved would have calmly awaited the facts and acted in accordance with the proper dictates. No one would have rushed to the false conclusion that somebody else was getting all the business and slashed his own price in a wild grasp for orders. The price standard of this product would not then have been demoralized. Therefore every manufacturer should heartily subscribe to the accumulation and publication of statistics on their products as an anchor of basic facts to tie to in times of trouble.

# *Recent Additions to Binghamton (N. Y.) Company's Plant*



APPROXIMATELY $3,000,000 was spent last year by the Binghamton (N. Y.) Light, Heat & Power Company for additions to property and equipment. Installation of a 30,000-kw. turbo-generator at the main station in Johnson City, a 110,000-volt line to Elmira and two 110/33-kv. substations constituted the major additions. The new turbine and the step-down substation at the main station are shown. To provide for the new unit 82.5 ft. was added to the end of the turbine room and 115.5 ft. to boiler room. Four boilers burning powdered fuel were also installed.



# Distribution "Revamp" Pays Dividend

West Penn Power Company makes changes, renewals and betterments that not only permit better service and provide for growth of load but bring directly or indirectly monetary benefits

By Merrill De Merit
*Distribution Manager West Penn Power Company, Pittsburgh, Pa.*

GROWTH of load, depreciation of old equipment and demands by customers for better service periodically require changes, renewals and extensions of a distribution system. To delay such revamping usually results in an increased cost of rehabilitation when it is finally performed at the risk of impaired service and operating economy during the meantime.

Since July, 1923, the West Penn Power Company has approved work orders for revamping its distribution systems to an extent of $810,181, and it is estimated that similar work for 1928 will require $150,000, making the five-year total $960,181. Evaluations of the direct and indirect benefits of this work have fully justified the expenditure. Among the major benefits derived, which will be evaluated later, are reduced distribution operating expense, decreased energy losses, increased energy consumption and revenue due to higher voltage, lowered pole cost due to joint construction, improved service and reduction of accidents. Benefits to which a cash value cannot be so readily assigned include elimination of unsightly facilities, which hasten demands for underground service; improvement of customer's service, reduction of operating troubles and facility with which cause of trouble can be remedied, reduction in lost revenue due to interruptions and the minimization of accidents, with the resultant human suffering.

The computed annual saving due to the distribution revamp for the work done so far totals $264,619, distributed as follows: Decreased operating expense, $95,913; reduced energy losses, $30,705; increased revenue due to higher voltage, $87,514; decreased maintenance due to joint construction, $28,457; change to four-wire, 4,000-volt primary distribution, $22,030. Including the savings contemplated by the 1928 plans, the total annual savings will be $301,619.

To determine reductions in operating expenses, division managers who have operated distribution systems both before and after rebuilding were asked to estimate the savings in the sections revamped. Operating expenses are not subdivided by districts, so that direct comparisons of actual charges are impossible. However, by covering many towns and by discounting estimates liberally conservative figures have been compiled which indicate that annual reductions and operating expenses have averaged about 10 per cent of the debit revamp work orders, which figure has been used, subject, of course, to check in each instance.

One of the division managers who was called upon to enable a fair estimate made the following comment: "Previous to the revamp five and sometimes six men were employed continually, in addition to the short line crew. These men worked in ........ and ........ on maintenance and operation and did some construction. Previous to revamping one of the towns (by far the larger) these men were unable to do any construction work because they were so busy on maintenance and operation. One truck was required for these men. The saving would be about four men and one-half the cost of the truck."

*New trussed-steel poles shown to left of wood-pole line*

The comment from another division manager reads: "Previous to the revamping six men and one truck were engaged continually for maintenance and operation of these districts in addition to the short line crew. These men did some construction work, but more overtime was spent on maintenance and operation than the entire time spent on construction."

In still another division the manager reported: "Eight men and one truck were continually engaged on maintenance and operation of these three districts in addition to the men who are now engaged on this work."

Each division manager advised that not only were these savings being made but that the service is better from the standpoint of interruption, and that additional interest is shown in safety work.

Evaluating these savings, they can be expressed as a percentage of the debit work order, averaged and applied to a large number of other revamp debit work orders made in exactly the same manner and under the same conditions. This method of calculating was used because operating and maintenance expenses are controlled more or less to follow the revenue, consequently direct comparison of charges before and after the revamp would not show the savings in expenses.

*Ramshackle hillside substation gives way to elevated-platform transformers*

Decreases in energy losses were calculated from current and voltage tests and copper wire and transformer constants. Annual savings were thus evaluated with fair accuracy, considering such energy to be worth 1 cent per kilowatt-hour.

Increases in revenue due to raise in secondary voltages were estimated in two ways: First, by taking actual kilowatt-hour consumption increases in the districts revamped and attempting by graphical methods to eliminate changes due to other causes, such as addition of new customers, sales of appliances, changes in rate, etc.; second, by determining weighted average service voltage before and after revamping, calculating the average voltage increase and corresponding consumption and revenue increase. The two methods check quite closely and furnish a fair measure of the added annual revenue due to revamping.

Considering the first method, predictions were made for five districts, which were revamped, as to the consumption which would have obtained in 1926 if the districts had not been revamped. From this prediction and the actual consumption of these districts the actual increase in kilowatt-hour consumption due to revamping was determined. This consumption was evaluated at $0.035 per kilowatt-hour as the increased revenue due to revamping. By using averages a percentage has been determined which can be applied to future revamps. From this can be determined the increased revenue which is accruing due to the revamping which has been done and which will follow.

### 3,983 Pole Locations Eliminated by Joint Use

Yearly savings due to joint construction are considered equal to one-half the annual charges on poles jointly used. Assuming the average joint pole to be worth $35 installed and conceding annual charges of 15 per cent, the savings were calculated for joint construction. It may be pointed out that up to 1928 during this rehabilitation period 12,207 poles were converted to joint use and 3,983 pole locations were entirely eliminated through improved layouts and planning.

In fourteen towns where the primary distribution was changed from three-wire, 2,300-volt to four-wire, 4,000-volt a total annual saving of $22,030 was made by eliminating 2,300-volt circuits, involving 161 wires valued at $151,347, and by saving pole space valued at $48,680. The net saving in capital expenditure was $200,027, giving the annual saving mentioned before of $22,030. In addition to the saving in distribution equipment, substation savings resulted because of reduced circuit positions, switches, regulators, etc. Saving in investment for these causes is estimated at $186,000 and result in annual savings at 11 per cent of about $20,000. (Not included in totals which are for distribution only.)

The changes which brought about these benefits involved the redesign of the distribution system to meet modified standards as to primary circuits, transformer layouts, secondary circuits, pole plants, joint construction, elimination of hazards and corrections to meet present specifications. The relative importance of these factors varied on different parts of the system and the total money available determined the degree of perfection of physical and operating conditions aimed at by the

## *Effect of Revamp on Future Work*

By the time all West Penn distribution systems have been revamped new conditions will prevail in two major respects: First, the system of continuous design will have simplified and smoothed out the process and quality of revamping necessary. Second, completed maps and records will have reduced the field work and expense necessary to determine accurately the conditions of distribution systems and need for improvement. Consequently, revamping will eventually become a continuous rather than a periodic process to which a schedule can be applied that was impractical heretofore.

For example: (1) Bad conditions will be eliminated and changes made in accordance with future plans, so that operating hazards and expenses will be reduced at the same time that capital expenditures for future additions are made; (2) increases in revenue due to revamping will accrue to the company continually instead of in jumps at times of general revamping; (3) more effective testing will enable more exact and better designs and the cost of testing will be reduced, because only one-third of the system need be tested each year; (4) revamping of construction will produce an improved load factor in construction; (5) with the aid of map records, revamping work can be accurately budgeted and expenditures anticipated; (6) the engineering work can also be budgeted and provided for in a better manner and at less expense for corresponding improvements; (7) additions made at any point in the system will fit in more closely with general plans than at present; (8) joint planning and joint construction work can progress to the best advantage and can be co-ordinated.

design. To date rehabilitation has attempted to correct undesirable conditions in the order in which they would render the greatest return for the money expended upon such improvements.

Selection of the primary voltage was based on existing voltage, tree conditions, distance from substations to load centers, availability of other voltages, rate of growth and cost of changes. With the voltage determined, the next decision was whether to use the "main feed and branch," "segregated territory" or "feeder and network" primary system. Distribution of the present and prospective loads and location of the existing primaries determined considerations at this stage.

Large savings in transformer capacity were made possible by taking advantage of the fact that it is both safe and economical to carry loads up to 160 per cent of the nameplate rating.

### FOUR-WIRE, 4,000-VOLT PRIMARIES

In nearly all West Penn towns the primary distribution circuits before revamping were operating at 2,300 volts. In many of the larger towns it has been found economical to change to three-phase, four-wire, 4,000-volt systems. In general, the advantages of this system accrue from the fact that the effective distribution voltage is really 4,000 volts, although 2,300-volt transformers and other equipment may still be used. In addition, the 4,000-volt system requires only about 44 per cent of the copper necessary in a 2,300-volt system for the same power transmitted and the same percentage of losses. Actually, one neutral conductor is used for two or three circuits and the saving is greater. Consequently, the number of circuits after substituting the 4,000-volt system is only one-third of that required for 2,300-volt operation. Consideration was also given to the disadvantages of the 4,000-volt system, such as the higher voltage and the grounded neutral. During stormy weather bad tree conditions and other weak points in insulation cause grounds and consequently short circuits. However, when such weak points have once been cleared operation is found to be as reliable as that secured with lines operating at the lower voltage.

*Single straight poles replace duplicate and leaning structures*

In many of the districts larger amounts of money than were authorized would have been required to bring the distribution to its ultimate standard immediately. However, a system of progressive or continuous rehabilitation has been incorporated so that a general revamp would not again be required. Essentially, this plan enables caring for future business by making additions rather than replacements. This procedure is particularly advantageous in selecting transformer capacities and locations because of the high rate at which domestic and commercial load densities are increasing. Since lighting loads are at a maximum for only a few hours each day, the possibility of carrying the peak at much greater than the continuous rated capacity of the transformer without exceeding prescribed temperature rises was recognized.

*Alley construction cleared up*

### SECONDARIES FOLLOW PRIMARIES

Tests and analyses developed several guiding principles for the design of secondary distribution circuits. These include proper use of two-wire and three-wire secondaries and economical location of transformers along the secondaries. In general, the line type of distribution is used with primaries following secondaries. Transformer locations were planned about every 500 ft. on No. 6 wire and every 700 ft. on No. 4 secondaries. Poles of sufficient height were installed at such locations where new poles were found necessary.

Continuous or progressive design is particularly valuable for secondary circuits. Replacement of secondaries is costly, so new loads should be cared for, first, by placing intermediate transformers on existing secondaries, and, second, if required, by replacing transformers with units of double capacity. The secondaries will then be carrying double the original load, but for only half the initial distances, and it would still be adequate although the total load served is 400 per cent of the initial load on these distribution facilities.

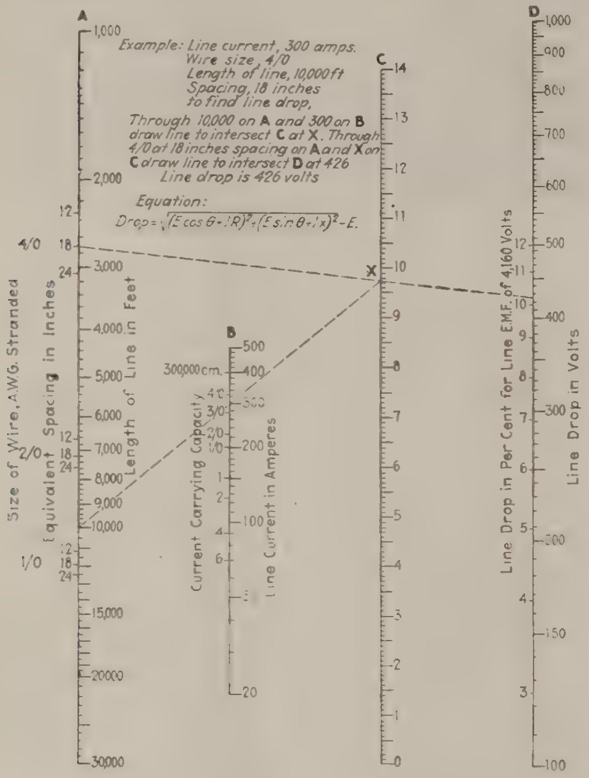
Expenditures for pole changes came under two general classifications: Those providing for joint construction of the utilities and those necessary because of depreciation and changes in pole sizes. Joint construction has been provided in most places except on main leads away from substations or where voltage or peculiar local conditions made independent pole lines preferable.

Dangerous conditions resulting from either depreciated equipment or inadequate clearances have been eliminated as discovered. Much unsightly plant has been replaced, particularly the offensive cases, but these changes were justified by other causes alone.

# Feeder Layout Chart

By R. W. Jickling and T. A. Robinson
*Assistant Electrical Engineers*
*City of Winnipeg Hydro-Electric System*

IN LAYING out residential feeders it was found that the same calculation had to be repeated a great many times in varying forms. The volts drop or regulation is required at peak-load conditions. This peak load may be assumed as at least 95 per cent power factor for lighting feeders. The variables to be chosen from are wire size, current, voltage drop, length of line and per cent capacity of regulator required to give good voltage at the base of distribution. To increase the usefulness of the chart the volt drop is given direct instead of in per cent of a certain line voltage. This means that the chart may be used for a 2,400-volt or 4,160-volt feeder equally well. The per cent drop for 4,160 volts is, however, shown in addition.



*Enables estimating voltage drop in three-phase lines at 95 per cent power factor and balanced load*

Starting with any one of the quantities, it is extremely easy to get the others without any intermediate calculations, as is necessary with most charts of this type.

The chart is based upon the following conditions:

Three-phase lines, at 95 per cent power factor, balanced load.
Spacing, 12, 18 and 24 in., being the equivalent spacing, or spacing of three wires in a delta arrangement.
Wire sizes, 1/0 to 4/0 stranded.
Current, 50 to 500 amp.
Distances, 1,000 to 30,000 ft.

The resistance of wire is taken at 20 deg. C. and for 97 per cent conductivity copper, as given in the N.E.L.A. overhead systems reference book.

Reactance for 60 cycles is as given in the N.E.L.A. systems reference book.

The allowable carrying capacities shown are the National Electrical Code standard for weatherproof wires.

Equation of drop = $(E\cos O - IR)^2 - (E\sin O - IX)^2 - E$

The chart, if carefully used, is accurate to within 2 per cent. If one considers how much the quantities themselves are likely to vary, this is quite sufficient for most ordinary purposes.

# Supervisory Equipment Inspections

By O. M. Ward
*Assistant Electrical Engineer Milwaukee Electric Railway & Light Company, Milwaukee, Wis.*

THE IMPORTANT functions performed by supervisory equipment requires that this kind of apparatus be kept always tuned to perfect operation. The only way that this end can be attained is by frequent and sedulous attention. The report form reproduced here testifies to the detail of the inspections of supervisory equipment which are made at intervals of one week on the system of the Milwaukee Electric Railway & Light Company. A copy of this report for each inspection is kept in the substation so that previous conditions of the apparatus are known at every inspection.

## *What Is the Matter with*

# Industrial Electric Heat?

A billion-dollar load goes begging in the electrical industry. Study of existing conditions shows how the power companies can cash in on enormous new-business possibilities

By T. P. Kindig

*Western Editor* Electrical World

THAT the power industry should be vitally interested in building up the industrial electric heating load there can be no question. Every kilowatt of this class of business means additional load and revenue for the central-station company. There are at least 50,000,000 kw. of this type of load which should be connected to the central-station company's lines. This load would consume, in round numbers, 100,000,000,000 kw.-hr. per year and return about $1,250,000,000 gross annual revenue.

Yet with these possibilities staring it in the face, the power industry—in fact, the entire electrical industry—seemingly regards the heating load with lackadaisical indifference. The efforts put forth to get this business are puerile and infinitesimal in proportion to what it means not only in the sale of kilowatt-hours but also the sale of electrical equipment to supply and control the use of energy for heating purposes. Why does such a condition exist? What is the matter with industrial heating? Why doesn't it go ahead faster? Whose fault is it?

A review of the present status of industrial electric heating from the standpoint of the manufacturers of heating equipment reveals some most interesting and rather startling conditions in the attitude of power companies toward this class of business. The heating-equipment manufacturers believe that the central-station companies are of great potential value in developing the use of industrial electric-heating apparatus. In fact, they believe the power companies should be the ones most concerned in seeing these installations multiply, because they will receive the revenue from energy consumption year after year, while the equipment manufacturer must realize his profit from the direct sale and orders for additional apparatus. However, the manufacturers of industrial heating equipment have found that there is still much to be desired in the attitude and degree of assistance that should be expected from the local central-station company in the sale and installation of this type of apparatus. In many cities the manufacturer, while desiring its co-operation, is reluctant to have the local power company participate in the negotiations with the customer.

That such a condition should exist is difficult for many power company executives and heads of commercial departments to believe. But facts cannot be denied. The experiences and opinions set forth in the following paragraphs have been placed before a number of utility executives and power sales engineers who have admitted that many of the conditions were true in their own companies. Also, in their opinion the utilities as a whole are putting very little effort back of industrial heating and much of this effort is ineffective and sometimes detrimental.

An examination of the facts shows that despite the enormous load and revenue which would accrue directly to the central-station companies, these very companies are themselves chiefly to blame for the relatively slow rate of growth of the heating load. In a large number of cases installations of industrial electric heating equipment have been made almost in spite of rather than because of any practical assistance from the power companies. That this is true would appear to contradict the fact that the utility sales departments have long recognized the value of the heating load and are striving with what available tools they have to get the business. But the fault does not rest with the utilities' power sales departments.

### Sending a Boy to Do a Man's Job

Failure to develop the heating load must be laid on the doorstep of the utility executive. In more ways than one the man upstairs in the front office has hindered rather than helped the installation of electric heating apparatus in the manufacturing plants of his customers. More than that, in most instances where the utility executive has finally consented to the addition of a special "heating man" to the sales force he has in effect "sent a boy to do a man's job." As a matter of fact, the power companies which have anything even approaching an adequate industrial heating sales force can be counted on the fingers of one hand. Here is a class of business which when properly developed will total two or three times the present motor load. However, the sales engineering support which a utility company will give to industrial electric heating is usually in inverse ratio to the potential volume. The power company has, say, five power sales engineers, and if it is well equipped, as utilities go, it may have one man who devotes his time to industrial heating.

Power companies are anxious and eager, wherever possible, to add to their motor load, but when the question of a heating load comes up there develops a surprising and unexplainable indifference on the part of the utility executive. This leads to the question, Are hot kilowatts less desirable to the power company than cold ones? Does it mean that the dollars received for energy used in an electric furnace are less profitable than those that go through an electric motor? It doesn't require a lengthy analysis to show the value of the heating load. Its high power factor and high load factor characteristics, together with frequent possibilities for off-peak operation, make it undeniably a desirable class of business.

Perhaps it is the sale of energy in large single blocks that has appalled some utility executives. A fair-sized electric furnace has a large demand and in twenty-four hours will consume a surprisingly large number of kilowatt-hours. Quite often individual installations of electric furnaces run into thousands of kilowatts. Recently the installation of a single heat-treating furnace called for a demand of 3,000 kw. This furnace is being operated 24 hours a day and is connected to the lines of one of the few power companies that is intelligently encouraging and building the heating load. In developing the installation of this furnace the manufacturer worked very closely with the local power company and its customer and the resultant operation of the furnace is highly satisfactory from every standpoint. However, contrast the attitude of this power company with that of the utility in another city where the same furnace builder tried to work with the local central-station company in the sale of heating equipment.

He first went to the power company to obtain its schedule of rates. He met with a cold reception and was told that the prospective customer could not have a primary power rate. Why? Because, the utility vice-president said, "an electric furnace load could not earn the rate." It took the furnace manufacturer half a day finally to convince this executive that the furnace which he proposed to install on the customer's premises not only was entitled to such a rate but that it would give the power company a more desirable load than many power loads which it already was serving under the same rate.

### *Some Questions for Utility Executives to Answer*

What have you done to develop the industrial electric heating load in your territory?

Are you sending a boy to do a man's job?

Are hot kilowatts less desirable than cold ones? And why?

Don't the power companies understand big business?

Do you know how much potential heating load there is in your territory?

Do you know how much gross annual revenue the heating load would add to your company's income?

Why, when the ratio of potential heating load to available power load is three to one, is the ratio of heating sales to power sales engineers one to three?

Why does the heating equipment manufacturer want and at the same time fear the sales assistance of many electric utilities?

What are the central-station companies going to do to right this situation and help get this business on their lines?

But that was not all. After the question of rate had been settled the manufacturer visited the power sales department, thinking that here he would be able to obtain the necessary information concerning power and service conditions in the customer's plant and that at least the power sales department would be glad to know of this prospective heating load. This is the reception he received at the hands of the power sales department. He was told that the power company did not want any furnace manufacturer "messing around" with its customers. Any negotiations to be carried on with this customer must be through the power company. In other words, this furnace manufacturer could not try to sell an electric furnace in that town.

It is no wonder that this electric furnace manufacturer says of the power company, "If you want to lose a sale or have it go gas or oil try to work through the power company. To sell an electric furnace in that town, get in, sell it, get out, install the furnace and when ready for service then tell the power company."

### Special Rate Not Wanted

There is an idea on the part of some power company executives that the manufacturers of electric heating equipment desire that special low rates should be set up for energy used for heating purposes. This is not true. What the electric furnace manufacturers do want is that the electric heating load shall be served at the standard power rate which will give the customer the benefit of high load factor and high power factor operation. Certainly a load which operates at very nearly unity power factor and has a yearly load power factor of 40 to 50 per cent should be more desirable to the utility company than a load whose power factor is under 75 per cent and whose annual load factor is less than 25 per cent.

Frequently the sale of an electric furnace is lost to some type of fuel-fired furnace. This happens not always because of the severe competition from the fuel-fired furnace manufacturers but because the power company has not wholeheartedly backed up the recommendations for electrical equipment. Again, the power company in endeavoring to get the customer the best proposition in the price of the furnace has called in several manufacturers. Different types of design and varying prices have been presented, and in the end a gas or oil furnace manufacturer walks off with the order. The power companies should provide themselves with industrial heating men who are sufficiently well equipped with a knowledge of the customers' needs and the electrical equipment available in the market so that they can recommend to the customer one or two manufacturers best fitted to supply the particular requirements. It is well for the central-station company to realize that a furnace manufacturer who builds both electric and fuel-fired equipment prefers to recommend electrical equipment. The profit is just as great and the manufacturer is more certain that the electric furnace will meet and hold up to specifications.

### Training of Salesmen Inadequate

In a number of instances where the power companies have delegated one or more men to handle the industrial heating business in the territory the training and experience of these men has been totally inadequate. It is true that competent and experienced heating men are scarce and the facilities for training men for such highly specialized work as the sale of industrial heating equipment could be greatly improved. Much credit must be given to the industrial heating committee of the National Electric Light Association, which has co-operated with the electrical manufacturers in holding a two weeks' training course each year where utility power sales engineers could study the theory and practice of industrial heating application. It could not be expected, however, that these courses would provide the power salesman with a complete working knowledge of the intricacies of industrial heating application. Some further practical experience is necessary, for, verily, a little knowledge is a dangerous thing in the hands of a novice. The man who is going to sell industrial electric-heating equipment needs to have, more than anything else, a very practical knowledge of the manufacturing processes in the industrial plant where the furnace is to be installed. The successful installation of an electric furnace does not depend upon a theoretical knowledge of either electrical or thermal formulas but, rather, a very practical knowledge of the production problems of an industry.

Development of electric heat-treating processes to their present state of practical and economical application has been possible largely through the persistent efforts of furnace builders working with the industrial plant operators to design equipment which would fit into production schedules and improve manufacturing processes. Credit for this development work must go mainly to the heating equipment manufacturers and to the industrial plants which have been willing to accept such a revolutionary change in heat-treating methods as the adoption of electrical equipment. Outstanding in electric heating development by central-station companies has been the work of the Milwaukee Electric Railway & Light Company and the Detroit Edison Company. What these two companies have done serves to illustrate what can be accomplished by an electric utility to promote the use of industrial electric heating in its territory.

### Constructive Suggestions Made

The need for broader training of industrial heating sales engineers and the responsibility for the extent of development to date are cited to show where it is possible for the central-station company to take a more active and profitable part in the promotion of this class of business.

Still another direction in which the electrical industry has been negligent in the development of the heating load has been its failure to lay out a comprehensive publicity program to promote this load. There has been no provision for promoting industrial electric heating through publicity, as has been done by the gas industry for the promotion of industrial gas.

Central-station executives should see to it that a careful survey is made of all industrial plants in their territory in order to evaluate the extent of the potential industrial heating load. They should determine what this amounts to in additional kilowatts and gross revenue and then set up a force of industrial heating specialists in proportion to the volume of business.

Sales engineers who are to specialize on this class of business should not only receive the instruction and training available through the N.E.L.A. industrial heating courses but some provision should be made whereby these men could receive practical experience both in the plants of the electric-heating equipment manufacturers and in the operation of these furnaces in industrial plants. Such training and experience would necessarily mean considerably more than mere inspection trips and should provide the men with actual working knowledge of the equipment.

Power companies should be careful to see, in recommending rates for the industrial heating load, that the rate schedules provide some reward to the user when warranted by high load factor and high power factor operation.

The power company and the manufacturers of electric-heating equipment should get together on a basis of closer co-operation not only in the sale of heating equipment but also in a well-thought-out educational and publicity program, some of this education and publicity to be directed toward the power companies themselves.

### What the Load Means

Every kilowatt of industrial electric heating load put on the lines of the central-station company means an added revenue of $30 to $40 per year, which will continue for many years. For every kilowatt of industrial heating equipment installed there must be provided from $100 to $200 worth of other electrical equipment, including generating, transmission, distribution, metering, wiring, control and other apparatus. Or, putting it another way, every dollar spent for industrial heating apparatus means that about $5 additional must be spent for electrical equipment to supply and control its operation.

## *What Utilities Can Do to Develop Industrial Electric Heating*

Get a true conception of the extent of this load in kilowatts and its value in dollars of gross revenue.

Give the utility sales department ample sales engineering personnel to handle potential business.

Encourage sales engineers to specialize in practical knowledge of industrial heat applications and where they fit into industrial processes.

See that rate structures are so drawn as to reward high load and high power factor when earned by heating load.

Stand back of furnace manufacturers' recommendations to customers.

Don't open the way for a fuel-fired installation by asking too many electric furnace manufacturers to specify and bid on the same job.

Don't try to recommend standardized equipment where special design and engineering are required.

Get together with the electric furnace and equipment manufacturers on a joint advertising and publicity program to develop the heating load.

Remember that the central station company is the greatest single influence for developing the electric business in its territory and act accordingly.

A picture of the industrial heating business looks about like this: There is a 50,000,000-kw. load which would earn at least $1,250,000,000 for the power companies. There is $2,000,000,000 of electric heat-treating equipment to be sold by the manufacturers of this type of apparatus. There will be $10,000,000,000 of generating, transmission, control and miscellaneous apparatus necessary to supply energy to this load. Both the central station and manufacturing branches of the electrical industry can ill afford to overlook this business much longer. They should stop hunting elephants with popguns and quit sending boys to do a man's job.

# Regulator Protects Penstock on Fluctuating Loads

### Feeder regulator mechanism actuates water rheostat to maintain minimum water velocity in long penstock of small hydro plant

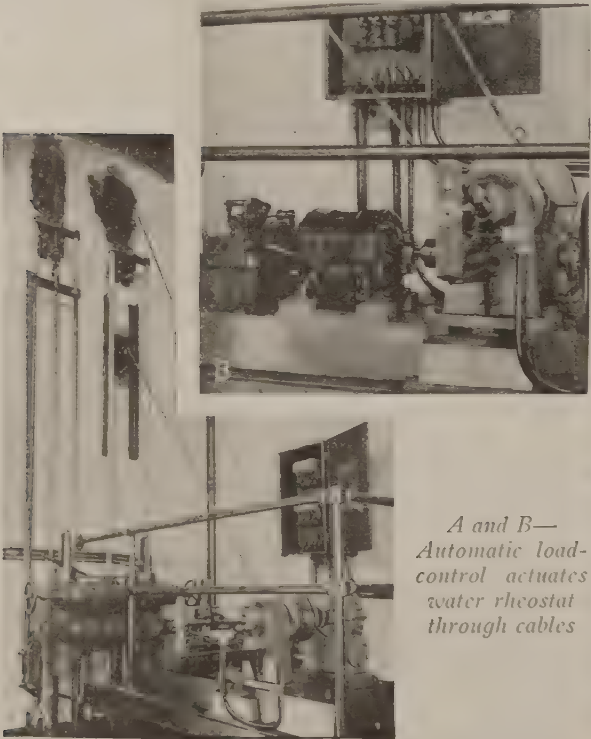
By S. C. Lindsay
*Assistant Electrical Engineer*
*Puget Sound Power & Light Company,* Seattle, Wash.*

PRIOR to the electrification of the Great Northern Railway between Skykomish, Wash., and the old Cascade Tunnel the Tumwater hydro-electric plant of the railway company was used to supply energy for hauling trains through a tunnel approximately 2 miles in length. The load varied from about 800 to 4,000 kw., with somewhat rapid increases in demand when accelerating trains and sudden decreases when the trains were through the tunnel.

The turbines in the generating plant are supplied through one wood-stave pipe line 8 ft. 6 in. in diameter and 11,832 ft. in length. The original design of the plant included a hydraulic governor mechanism, combined with an induction motor sensitive to frequency variations, which operated a water rheostat automatically to maintain a minimum load on the generators when trains were not in operation. This loading device was for the purpose of maintaining a minimum velocity of water in the pipe line to prevent it from collapsing upon sudden load demands. The plant is also equipped with a surge tank of limited capacity which assists in performing the same function.

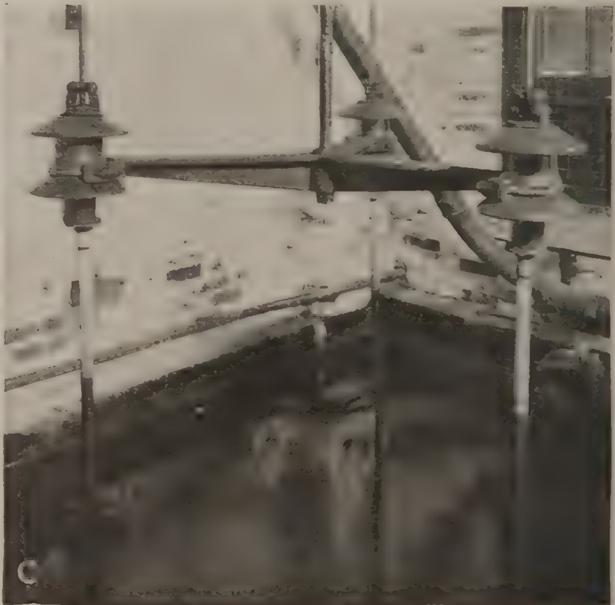
The operation of the plant was fairly satisfactory, but when the Washington Electric Company agent took over its operation in connection with increased power supply for the railroad the old emergency loading system, which functioned through frequency and water pressure, was no longer adequate. The increased demands of the railroad required that the Tumwater plant be paralleled with the Puget Sound Power & Light Company's 60-cycle system through frequency changers which gave practically a fixed frequency. Under these conditions, the problem was to find a regulating mechanism that would operate automatically to maintain a minimum load on the generators as a function of trail-load kilowatt demand. Operating experience had shown that a minimum load of 1,800 to 2,000 kw. on the plant would permit rapid acceleration of trains without excessive demands on the pipe line.

The device consists of a single-phase voltage regulator which through intermediary of a motor-driven cable drum raises and lowers the electrodes of a water rheostat. In the feeder regulator equipment a contact-making wattmeter was substituted for the contact-making voltmeter. The wattmeter is a polyphase curve-drawing instrument having special contacts to which the control circuit of the regulator mechanism is connected. A dead point exists in the scale between the 2,000- and 2,500-kw. load points, which prevents the electrodes of the water rheostat from continually traveling from one position to the other.



*A and B—Automatic load-control actuates water rheostat through cables*

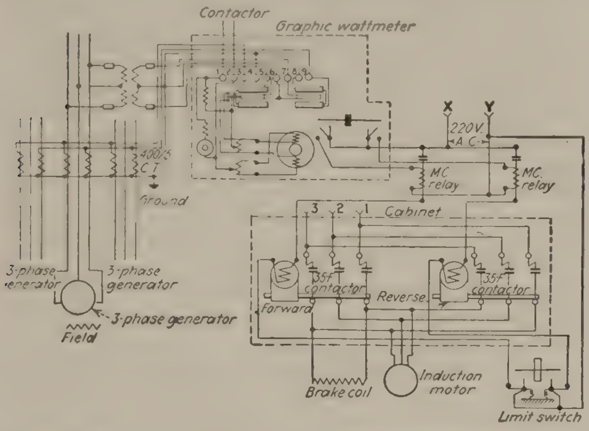
*C—Automatically actuated 6,600-volt water rheostat prevents pipe line rupture during fluctuating load*



---

*Under executive management of Stone & Webster, Inc.

When the load is more than 2,500 kw. the device does no regulating and the electrodes are out of the water. When the load drops below 2,000 kw. the electrodes are lowered to a depth that will hold the load to approximately that value. For total generator loads of 2,000 kw. the division of load between the railroad and the loading rheostat may be anything from 100 kw. on the rheostat to 1,900 kw. on the railroad, or 100 kw. on the railroad to 1,900 kw. on the rheostat. The device will regulate for load changes of 50 kw. and can be set to regulate more closely, if desired.



*Connections of special curve-drawing wattmeter which actuates feeder regulator controlling water rheostat*

A motor drives a shaft carrying an 8-in. drum on which is wound the cable for raising and lowering the electrodes. An extension of the shaft carrying the drum is threaded and carries a nut which operates the limit switches. A 3-hp. motor is so geared that the rate of travel of the electrodes is approximately 1 ft. per second. An electrode speed of 1½ ft. per second, first tried, proved too fast, as the device did the governing for the plant, instead of the waterwheel governors, at loads less than 2,000 kw.

The rheostat tank is concrete, 8 ft. x 9 ft. by approximately 10 ft. deep. The electrodes are 1¼-in. iron pipe spaced on an approximately 3-ft. equilateral triangle and directly connected to the 6,600-volt generator bus through an oil circuit breaker. A small quantity of water from the penstock is kept flowing continuously through the tank to keep the temperature down. The resistant is maintained low enough to carry a load of 2,000 kw. when the electrodes are fully immersed by a salt solution, admitted to the rheostat tank as required by the station operator.

The water supply for the plant is in excess of load requirements for several years to come, which led to the adoption of this scheme. The installation was made at a cost not exceeding $1,500, as compared with estimated costs of from $10,000 to $12,000 for other schemes considered. The device has been in operation since Feb. 1, 1927, and its performance has been highly satisfactory.

This special adaptation of apparatus was made by the Seattle shops of the Westinghouse Electric & Manufacturing Company under specifications furnished by the writer.

# Service Testing of Meter Transformers

## How the meter department of the Southern Power Company tests instrument transformers in the field

By B. J. Brown
*Superintendent Meter Department, Dubre Power Company, Charlotte, N. C.*

Testing watt-hour meters in service has been reduced to a fine art and work in the field can be done with practically as high an accuracy as in the test room. The great majority of meters will remain accurate for months, even years, but where large blocks of power are measured it is customary to test every few months to find the occasional time that one is not correct and also to satisfy the management that the power is being accurately measured. The testing of instrument transformers in service has not been developed to the same high plane of proficiency. While instrument transform-

*Special truck used by Duke Power Company for field test work*

The following apparatus is carried on the truck:
Three insulated sticks with heavy insulated leads for connecting the potential transformers to the high side of the circuit.
Two 2,600-volt, 20:1 standard potential transformers.
Two 600-volt, 6:1 standard potential transformers.
Two 500-, 1,000-, 1,200-amp. standard current transformers.
Two 2,500-3,000-amp. standard current transformers.
Secondary lead with snap switches.
One rotating standard.
One indicating voltmeter.
One indicating ammeter.
Rubber gloves.
Slide rule and test block.
Four sections ladder.

*Accuracy of Metering Equipment Where Instrument Transformers Are Used*

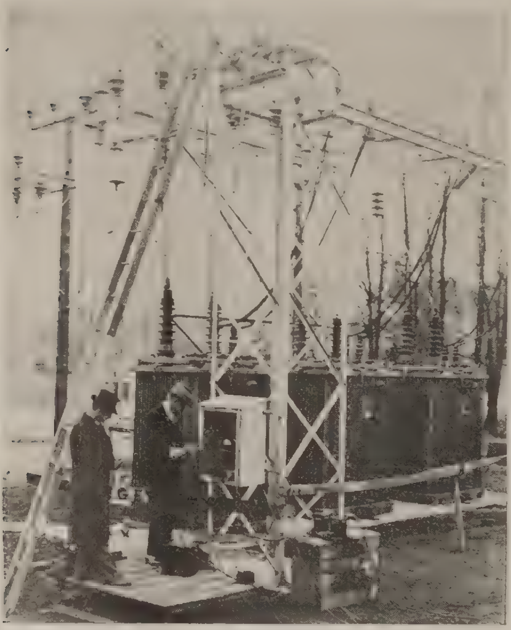
*These three cases were: (1) One current transformer secondary grounded due to heavy short circuit, 7 per cent slow. (2) Partial ground in secondary cable, 14.1 per cent slow. (3) Partial ground in current transformer secondary, 17.1 per cent slow.

†A550-volt self-contained meter was found 40 per cent fast due to lightning injuring coils.

ers have a high degree of initial accuracy and the majority of them hold it over a considerable length of time, they are exposed to lightning, short circuits and grounds, the heavy artillery of trouble, making it advisable to test frequently under service conditions.

A number of years ago several different sized portable standard current and potential transformers using an indicating polyphase wattmeter were tried out by this company in an endeavor to test and establish corrective constants on complete meter and instrument transformer installations. It was soon found, however, that these tests would not agree under varying conditions and the work was consequently abandoned. It is now realized that the so-called portable standards were built light and had even worse calibration curves than the commercial types upon the lines.



*Instrument transformers are tested in the field by the Duke Power Company*

Shortly afterward some German precision type current transformers with hinged joints, designed for slipping over busbars, were obtained. These were checked by the Bureau of Standards for accuracy after opening and closing and subsequently used on special tests over a number of years. Recently the transformers were rechecked by the bureau and found O.K., showing that good hinged type transformers can be built to hold up.

Later, the practice was initiated of removing the transformers and testing them in the meter laboratory. This required a large supply of extra transformers, nearly all of the changes had to be made on Sundays and the installations were so scattered that only a few installations could be changed. With only a limited number of Sundays in a year, this method of testing was far from satisfactory and efforts were directed toward developing a means of testing that could be used to check the transformers while in service any day of the week.

Considering safety and freedom from interruption of prime importance, as many of the customers' circuits were of heavy current rating, and remembering the reliability and accuracy of the German instrument transformers, it was decided to try to secure current transformers that could be slipped over the supply lines. These German transformers were rather heavy and cumbersome and could not be obtained in sizes smaller than 3,000 amp., so the matter was taken up with American manufacturers and very satisfactory units secured which, while possessing rather large ratios and phase angle curves, did not vary nor appear affected by the opening and closing of the gap. The following sizes were tried: 200 amp., 500 amp., 1,000 amp. and 1,200 amp. While the 200-amp. transformer did not prove satisfactory, except for high power factors and when well loaded, the other transformers have been used for several years and tests that have been made on the same meter installations by different individuals check very closely.

The actual metering of customers' circuits is done on the load side of the power transformers. The instrument transformers are usually of the indoor type, mounted in galvanized boxes, and installed on the steelwork of the customer's substation. Conduit is run from the metering transformers to the meter box, located at a convenient spot at the base of the steelwork of the substation or, if of the pole type structure, placed upon one of the poles. The meter is sealed and the box is also locked. A window enables the meter to be read.

The arrangement of the testing apparatus used in checking the accuracy of these installations is shown in the accompanying illustrations. This apparatus consists of the following: Two standard potential and two standard current transformers, voltmeter, ammeter (it is more accurate to calculate power factor) and a polyphase standard integrating watt-hour meter.

The meter is tested first by connecting the polyphase integrating watt-hour meter in series with it on the secondary side of the transformers. This determines the error of the meter under service conditions. Next, a check is made with the standard meter connected. The difference between these two tests gives the combined inaccuracy of current and potential transformers. Then the potentials of the standard meter are changed to the secondary of the service transformers on the test block. The difference between this and the previous check gives the inaccuracy of potential transformers and the difference between this and the first test on the meter gives the inaccuracy of current transformers.

When these instrument transformers show a variation of 1½ per cent from correct they are changed and then retested in the laboratory to determine the trouble. Tests made during the last three years are given in the accompanying table.

A special truck equipped with all the apparatus that is required for any kind of a test has been used in this meter testing work.

In regard to the time and expense of this testing work, costs differ so much throughout the country, due to local conditions, that it is difficult to compare them. On the Duke Power Company system the customers are scattered over a wide area, averaging from 60 to 75 miles from the laboratory, located in Charlotte. On a number of tests reviewed the cost of time and expense per installation averaged $4.50, while the estimated cost of installing tested transformers and taking the replaced transformers back to laboratory and testing was $16.50 per installation.

# Ground Resistance Testing

New method of investigation described. Instruments and test procedure outlined. Results of tests and analysis of operation indicated

By W. B. CRAIGMILE
*James G. Biddle Company, Philadelphia, Pa.*

TESTS of the resistance of ground rods or plates and of grounded structures to earth have been made for many years. All methods of measurement employed in the past have disadvantages, which lack of space here prevents discussing, but which are fairly well understood. However, one objection common to all of these methods is that some calculation is necessary to obtain the result.

Tests by the new method are made with the recently developed "megger" ground resistance tester and require the use of two auxiliary grounds. The resistance of the ground under test is given by the deflection of the pointer on the scale of the instrument in one operation, directly and without any computation. The principle of operation is shown in Fig. 1.

Current is supplied by a self-contained direct-current hand-generator, and after passing through the current coil of the ohmmeter is changed into alternating current for the test by means of a commutator or current reverser. The potential drop across the ground under test is picked up at $P_1$ and $P_2$ and converted into direct current for actuating the potential coil of the ohmmeter. Thus the result is shown at once by the direct-current ohmmeter, having all the advantages of sensitiveness and accuracy of this type.

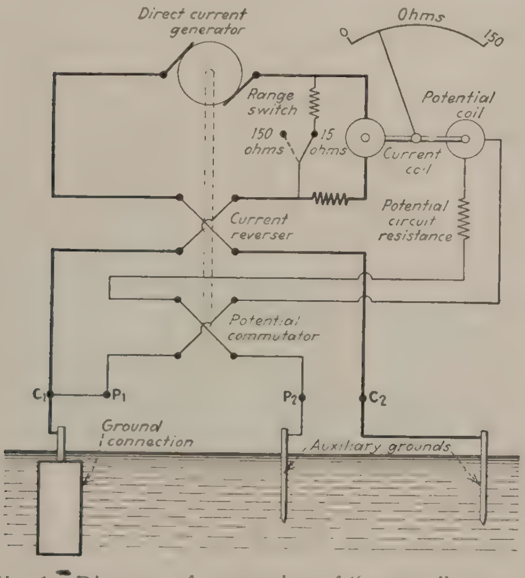


*Fig. 1—Diagram of connection of "megger" ground resistance tester*

The two coils of the ohmmeter are mounted on the same shaft and work in opposition in a permanent magnet field. Thus the instrument is a true ohmmeter and indicates $R$ as a ratio of $\frac{E}{I}$, unaffected by the exact voltage generated in the armature, or strength of the magnetic field. The current reverser and potential commutator are on the same shaft as the armature of the generator and so run in synchronism, whatever the speed.

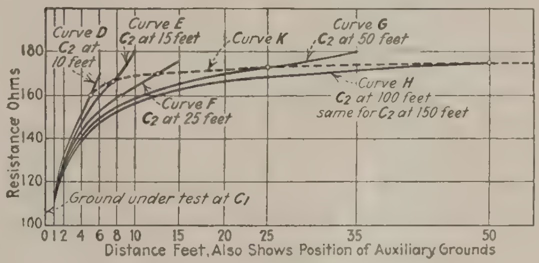

*Fig. 2—Results of ground tests*

Variation of resistance with spacing $C_1 — C_2$. Ground under test at zero feet. Current return ground at 10, 15, 25, 50, 100 and 150 feet. Resistance measured at several points between $C_1 — C_2$.

As the current in the ground circuit is alternating, errors due to stray currents—either direct or alternating—in the earth are avoided. At normal speed of turning the handcrank the frequency of the test current is 50 cycles per second. Should there be stray current in the earth of the same frequency as the test current the pointer becomes unsteady. The remedy is very simple—turn the crank slower or faster so as to make the frequencies of the test current and stray current differ from each other.

The resistance to earth of the auxiliary current ground $C_2$ does not at all affect the accuracy of the test; it can make no difference except in the sensitiveness of the ohmmeter. Tests show that even if the resistance at $C_2$ is several times the range of the instrument the ohmmeter remains amply sensitive.

The potential circuit of the ohmmeter is of high resistance so as to minimize the effect of the resistance to earth of the auxiliary potential ground $P_2$. In all but the lowest range of the instrument the potential circuit has a resistance of a least 10,000 ohms; thus a wide variation in the resistance of the auxiliary potential ground is permissible without causing any serious error in the indications. The instrument is compact and of convenient form and weight to be carried easily from place to place.

In most cases the resistance of a water pipe to earth will be found to be small. Where considerable resistance exists it is usually due to joints made with some poor-conducting material. The resistance of a ground connection referred to a water pipe can be measured directly by the "megger" ground resistance tester. It is necessary only to join $C_1$ $P_1$ (Fig. 1) to the ground under test and $C_2$ $P_2$ to the water pipe. If the resistance of the water pipe to earth is suspected to be more than a few tenths of an ohm it can be tested in the usual manner, joining $C_1$ $P_1$ to the pipe and using auxiliary grounds for $C_2$ and $P_2$.

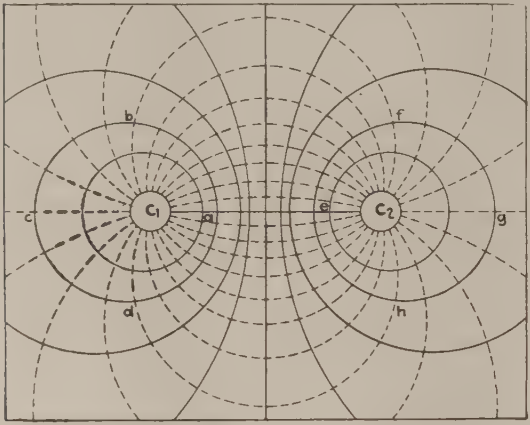

*Fig. 3—Current and equipotential lines between two electrodes near the surface of the ground*

Results of a test are plotted in Fig. 2. In this test a series of stakes made of $\frac{3}{4}$-in. galvanized iron pipe were driven 3 ft. into moist, sandy loam. Stakes were driven at 0, 1, 2, 4, 6, 8, 10, 15, 20, 25, 35, 50, 65, 100 and 150 ft. The resistance to earth of the stake at 0 ft. ($C_1$ of Fig. 1) was determined to be 175 ohms. Repeated measurements of this resistance and the distribution of resistance were made for spacings $C_1 — C_2$ of 10, 15, 25, 50, 100 and 150 ft. respectively.

The curve for a spacing of 150 ft. $C_1 — C_2$ is coincident with curve $H$ for 100-ft. spacing within the probable limits of observation. Curve $K$, shown dotted, is drawn through the mid-point values of the other curves.

It will be noticed that for spacings of $C_1 — C_2$ of 10, 15 and 25 ft. the midpoint readings are correct within an error not exceeding 10 per cent. However, the slope of the curves at their mid-points is quite steep, so that a slight misplacement of the potential stake may result in a considerable change in the reading. Also for close spacing we must bear in mind that if the resistances to earth at $C_1$ and $C_2$ are not nearly equal in value the curves will be distorted and the reading at the mid-point may not give a true idea of the actual resistance of the ground under test.

From curve $G$ for a spacing of $C_1 — C_2$ of 50 ft. the difficulties mentioned can be seen to be much reduced, and for spacing of 100 and 150 ft. $C_1 — C_2$, curve $H$ shows that the difficulty appears practically not at all. Therefore, it seems safe to say that the auxiliary ground for current return, $C_2$, should be at least 100 ft. from the ground under test, $C_1$, and the auxiliary potential ground approximately 50 ft. from the ground under test. For commercial accuracy the distances may be reduced to 50 ft. and 25 ft. respectively. The curves shown are typical of many obtained and will serve as examples.

Let $C_1$ and $C_2$ of Fig. 3 be two electrodes near the surface and carrying into and out of the earth. If the electrodes are not large compared to the distance between them, and the surrounding earth is of uniform quality, the current distribution and equipotential lines at the surface of the earth will have the general form shown in the figure. The dotted lines represent current flow and the solid lines represent equal potentials, although no attempt has been made to draw them to scale.

The curves, Fig. 2, show that for proper spacing of $C_1 — C_2$ to measure ground resistance the electrodes will usually be relatively small and relatively near the surface of the earth; therefore we need consider only the distribution as in Fig. 3, at the surface of the earth. If we measure the flow of current into the earth and the potential from $C_1$ to point $a$ we can obtain a value of resistance. A measurement to any point on the line $a$, $b$, $c$, $d$ will give the same value. Therefore the equipotential lines become lines of equal resistance.

Suppose that $C_1$ and $C_2$ are far enough apart so that a measurement of resistance on the line joining them and taken anywhere between $a$ and $e$ gives a resulting value of a sufficient degree of accuracy. (See Fig. 2, curve $H$.) Then a measurement on any equipotential line passing between $a$ and $e$ will give an equally good result.

Heretofore we have assumed that in measuring resistance by the single-test "megger" method (or the a.c. fall of potential method) points $C_1$, $C_2$ and $P_2$ should be in a straight line. We now see this is not necessary; $P_2$ can be placed anywhere except within two relatively small restricted areas, *abcd* and *efgh*. Thus $P_2$ may be placed far to one side of the line joining $C_1$ and $C_2$ or back of $C_1$ or $C_2$.

In conclusion, it is important to note that all that has been said regarding the spacing of auxiliary ground connections applies to any of the various methods in common use for measuring ground resistance.

## Simplified Bus Design at Siegfried

THE bus structure at the new Siegfried (Pa.) substation of the Pennsylvania Power & Light Company is constructed of 5-in. steel tubing welded together. The portion indicated in the accompanying illustration is that serving to connect the circuit breakers to the 220,000-volt line. The unusual design of bus supports presents an illusive impression of the real proportions. Note workman at right. Siegfried will serve as a tie-station in the 220,000-volt, 200-mile transmission ring connecting the systems of the Philadelphia Electric Company, the Pennsylvania Power & Light Company and the Public Service Electric & Gas Company.

# Carrier-Current Control
## *for Street Lighting*

San Francisco has one of first installations. System eliminates substation street lighting feeders and control apparatus. Transformers installed near load center

By R. Roy Cowles

*Assistant Engineer Department of Engineering*
*Pacific Gas & Electric Company, San Francisco, Cal.*

Vacuum tubes and the principles of radio communication which are being utilized by power companies for communication over transmission lines and for remote signaling and relaying are now entering the field of street-lighting control. Although the remote control of street-lighting circuits by carrier current has been under development for more than four years and has been watched with interest by utility engineers, one of the first commercial installations ever made has just been completed in San Francisco by the Pacific Gas & Electric Company.

The system consists essentially of a transmitting set in the substation and a receiving set centrally located with respect to the circuits to be controlled. The carrier-current equipment operates over one phase of a three-phase, 4,000-volt feeder through capacitor couplers in the substation and out on the line. In the substation there is a control transmitter connected to a line tuning unit, the latter being connected to the phase wires through fuses and capacitors on the line side of the feeder voltage regulators. The receiving set is located on a pole approximately 5,000 ft. from the substation and consists of a control receiver connected to the same two-phase wires through fuses and capacitors. A 600-watt, 2,300/115-volt transformer on the same pole supplies 115 volts for the operation of the receiving control circuit. Three single-pole, 2,300-volt oil switches are mounted on a pole one span away to avoid congestion. These energize the street-lighting transformers from the 4,000-volt feeder. Two No. 6 wires are run between the control receiver and the oil switches for operation of the latter.

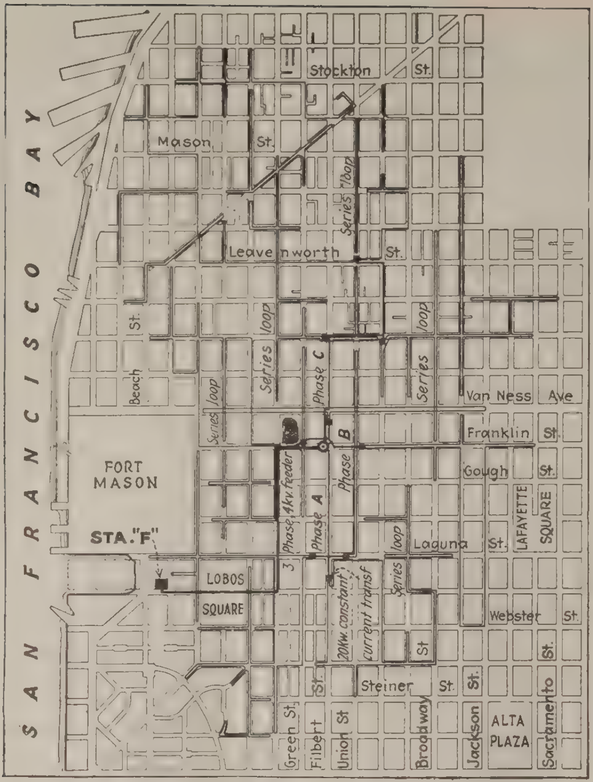
The oil switches are connected through inclosed type cutouts to the individual phase wires of the feeder. Three separate phases are run from the oil switches in different directions to supply the various constant-current regulating transformers located in the vicinity. There are at present nine 20-kw. transformers operating from the control. Connections for the apparatus involved in carrier-current street-lighting control are shown schematically in the accompanying diagram.

The transmitting circuit used is a Colpitts oscillating circuit using the full wave self-rectifying principle. The transmitter is rated at 100 watts, using two 50-watt tubes, one operating on each half of the supply voltage cycle. It delivers 2.5-amp. radio frequency into the 4,000-volt feeder. Filament and plate voltages are supplied from a power transformer. During one-half of the supply voltage cycle the voltage impressed on one of the tubes is positive and on the other negative. The tube using the positive voltage oscillates, while the other tube stays idle due to the negative voltage impressed upon it. Across the oscillating circuit is the primary of the output transformer, the secondary being coupled to the outgoing feeder by means of the line tuning unit and coupling capacitors.

*Three 2,300-volt, pole-mounted oil switches operated by control receiver in weatherproof box on pole at right*

In the view at the left fused cutouts are on the opposite side of the pole. In the illustration at right the 4,000-volt feeder is shown on the top cross-arm, below which are the fuses and line connecting capacitors.

The transmitter is adjustable to three frequencies, 35, 40 or 45 kilocycles. This is far below the broadcast frequency band of 550 to 1,500 kilocycles and has caused no interference with radio broadcast reception. The transmitter is adjusted to 35 kilocycles, which was found by test to be the most efficient frequency for the particular



*Territory included in carrier-current street-lighting control*

feeder circuit used. By long or short time intervals during which the transmitter operates the same frequency is made to serve for both turning the lights on and off. The time interval for closing is four seconds and for opening fourteen seconds.

The receiver is a simple biased detector circuit using one UX-210 tube. Filament and plate voltages are obtained from a small transformer. The tube is always energized, but the grid is so biased with alternating current that no current flows in the plate circuit until a voltage is impressed on the receiver input. The plate current output of the tube is 3.5 milliamp. although the polarized relay which it actuates will operate on as low as 0.8 milliamp. The plate current energizes a polarized relay, which in turn energizes a time selector relay operating at 120 volts a.c. This relay closes after an interval of four seconds and opens after an interval of seven seconds and operates the control contactor, which in turn controls the oil circuit breakers on the street-lighting circuits. Push-button control is provided so that the time selector relay may be closed manually if desired.

Before turning the equipment over for operation, tests were made by the engineering department to determine certain features. It was found that: (1) Street lights can be turned off immediately after being turned on, but cannot be turned on again until the selector relay in the receiving set has reset itself, its time interval being 45 seconds. (2) When street lights are on loss of voltage will cut lights out, but they will come on again when voltage is restored. No adjustments need be made at the transmitter.

### Flexibility of System

This control system as now installed at Station F can be expanded considerably with the addition of minor equipment only. At present one transmitting set operates one receiving set controlling approximately 3 square miles of street-lighting area operating on the same time schedule. The transmitter panel is equipped for three control circuits, making it possible to provide control for two more 4,000-volt feeders by simply adding a line tuning unit and two capacitors to each feeder controlled and by installing the necessary control receivers and capacitors at convenient points out on the line. *Schematic diagram of carrier-current street-lighting control* the present installation the oil circuit breakers can handle three times the present street-lighting load, or the phase wires can be extended to provide for new areas.

The center of load for the street lighting in the present control area is approximately 5,000 ft. from the substation, but the range of the equipment is greatly in excess of this distance. The polarized relay of the receiver will operate on 0.8 milliamp., as previously mentioned, although it is now receiving 3.4 milliamp. Thus the receiver would still operate successfully if it were moved to a point several miles distant from the substation. Since a receiver draws virtually no radio-frequency current from the feeder it is possible to connect a large number of receivers to a feeder without reducing the control radius of the station transmitter. In addition to this fact the number of feeders to which one transmitter can be connected is limited only by the number of feeders radiating from a single substation. Hence the area that can be controlled by one transmitter is dependent upon the distribution feeder system rather than any limitations of the carrier-control system.

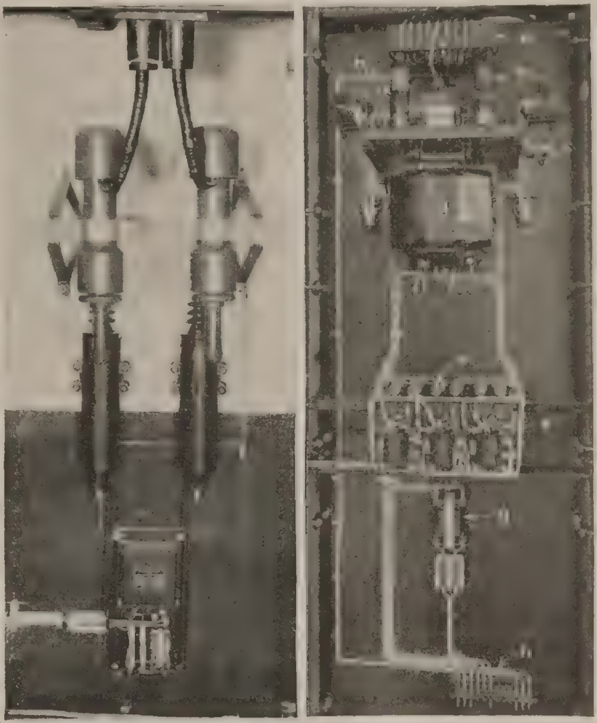
### ADVANTAGES OF SYSTEM

Carrier-current control makes possible the use of the multiple-feeder system of street lighting, which is more reliable and subject to less trouble than straight series systems fed from the substation. Elimination of the constant-current transformers from substations has made possible economy of space and reduced cost and avoids the excessively long series loops, with consequent high voltage, which have been a source of trouble and frequent interruption in the past.

The disadvantage of the multiple-feeder system is its cost and the resulting congestion of poles and underground conduits in the vicinity of the substations. Carrier-current control makes possible the elimination of that portion of the feeders from the substation to the point of control, also substation switching equipment, etc. This represents a large percentage of the cost of the street-lighting system. Carrier-current control of street lighting fed from commercial feeders permits taking advantage of the diversity between commercial load and street-lighting load, thus utilizing feeder copper and substation facilities at greater efficiency.

Pilot wire or some similar form of wired control might in certain favorable cases be used instead of carrier current to accomplish the same purpose. The congestion of poles and underground conduits in the vicinity of the substation as well as the cost would, however, in most cases eliminate such systems from consideration. Moreover, pilot wire control must of necessity be limited to very short distances, while carrier-current control has no such limitation.

A brief historical review of the street-lighting practice of the Pacific Gas & Electric Company and the considerations leading up to the use of carrier-current control may be of interest. A large percentage of street lighting on the system of this utility had been supplied from constant-current transformers installed in the substations. As cities grew and demand for street lighting increased, series circuits were expanded by adding more wire, increasing the number of lamps per circuit and including more territory in a single loop. In many cases it was necessary to take new series circuits out of the substations as the constant-current transformers were becoming overloaded. Many of the constant-current transformers were of 70-kw. capacity, operating at 7.5 amp., which made the normal voltage approximately 10,000 volts. In case of an open circuit, the voltage would rise considerably above this value. As these series circuits grew they eventually reached extreme lengths, one circuit in Oakland being more than 60 miles long. As a result of the extreme lengths of these series circuits and the consequent high voltage they were subject to considerable trouble.



*Line tuning unit and rear of carrier control panel*

Tuning unit is connected to 4,000-volt feeder in substation through tetrachloride fuses and capacitators.

The control panel is equipped for the control of three separate feeders. Flexibility of carrier current street-lighting control permits the operation of midnight lights or other schedules if desired.

(*a*) Output transformer. (*b*1, *b*2) Two vacuum tubes. (*c*) Test key. (*d*) Power transformer. (*e*) Red and green lights indicating "on" and "off." (*f*) Position relay—suitable for three-circuit controls. (*g*) Line switch—110-volt a.c. from supply circuit. (*h*) Terminal block for connections.

It was therefore apparent that changes must be made in the street-lighting system to reduce the number of interruptions and consequently improve the service. Analysis has shown that for the territory involved a series incandescent lamp system was more economical than a multiple system. It was readily apparent that if series street lighting was to be used the number of miles in each circuit must be materially reduced, and similarly the voltage and the number of lamps per circuit. The space occupied by the constant-current transformers in the substations was also of considerable importance, and as the substations became crowded, or as new substations were built, this space became increasingly valuable. Two considerations, therefore, became of great importance, the removal of constant-current transformers from substations and reduction in length and voltage of series circuits. These considerations led to the adoption of the following street-lighting principle, which was put into effect about five years ago:

Constant-current transformers, all of 6.6 amp. secondary, to be installed on the pole or in the manhole at the most convenient locations.

Size of constant-current transformers to depend upon the average size of lamps. Since the average number of lamps per circuit is 60, it works out that the most economical size for San Francisco division is 20 kw. and for the other divisions 10 kw. This arrangement keeps the voltage on the series circuit down to 3,000 in San Francisco and 1,500 in the other divisions.

The constant-current transformers are fed by 4,000-volt, three-phase, four-wire multiple feeders, which are switched at the substation and treated exactly as any other distribution feeder with the exception that there are no feeder regulators. Where lights are required to be switched on different schedules, such as all night and midnight, one of the phases is used for that schedule, whereas the other phase may be used for other time schedules. Where all of the street lighting is on the same schedule, the three phases are run out as single-phase feeders to supply different areas. In a few cases the principle of "cascading" is followed, whereby a series circuit will operate the series coil of a 2,300-volt oil switch, which in turn provides excitation for another series circuit through a constant-current transformer.

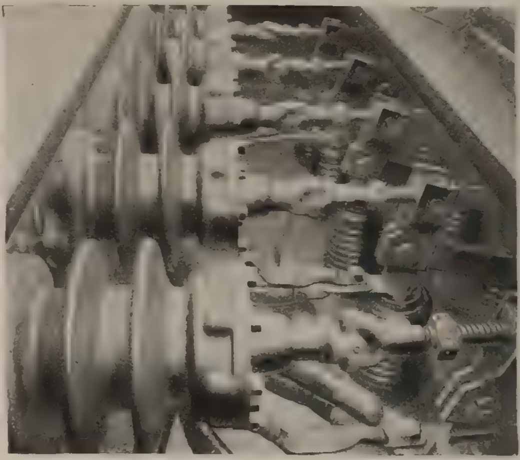
Experience with multiple electrolier circuits supplied by 4,000-volt, three-phase feeders had already shown that the same degree of reliability which had been obtained from distribution feeders of the same type and voltage could be expected from such street-lighting feeders. By shortening the length of the series loops and reducing the voltage it has been possible to reduce greatly the number of interruptions and improve the service, and by removing the constant-current transformers from the substations much valuable space has been saved and capital investment reduced.

At the time the above general plan was adopted engineers of the company were considering other types of control whereby distribution feeders could be utilized in their existing form and constant-current transformers installed on poles or in manholes. At that time consideration was being given to oil switches operated by some type of pilot wire, or carrier-current control over the 4,000-volt distribution feeders. The latter method was favored, but it was not until early in 1927 that the company felt that carrier-current control had progressed to the point where it could be regarded as reliable. One complete control unit was installed during the summer of 1927, and has functioned successfully since that time.

# Transformer Disconnecting Switches in Oil-Filled Potheads

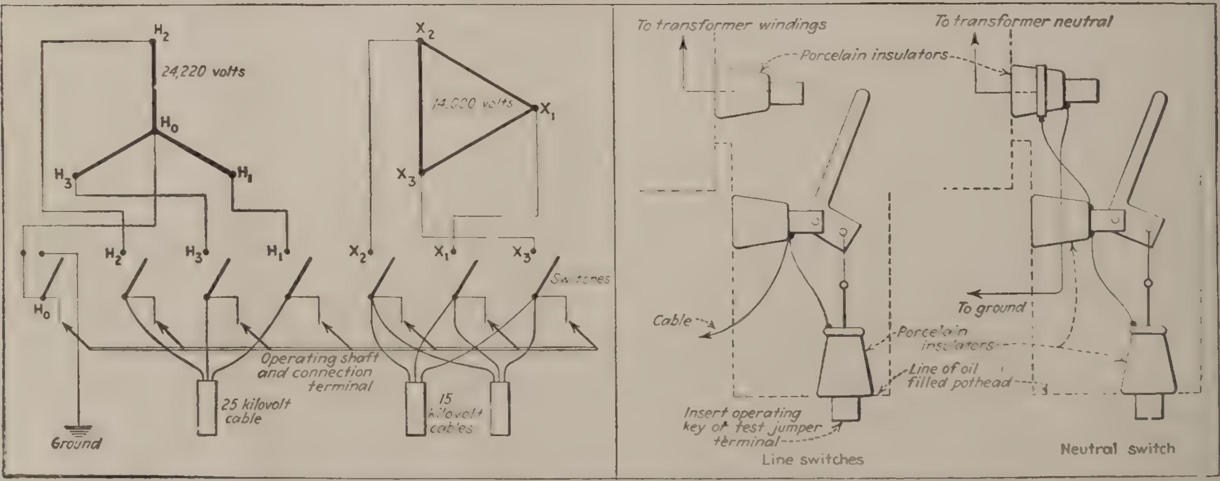
By Wellen H. Colburn
*Edison Electric Illuminating Company of Boston*

REFERENCE was made by the writer in a recent article (Electrical World, Oct. 22, 1927, pages 845 to 847) to special disconnecting facilities installed in oil-filled potheads on transformers of the Boston Edison Company. The accompanying illustrations show the scheme in more detail than was presented in the original article.



*Interior of oil-filled pothead showing bushings and switch-operating shafts*

The above illustration of one of these potheads shows the arrangement of insulating bushings and switch-operating mechanism in a field installation. The four bushings and associated operating shafts at the top of the illustration are on the 24-kv. connections of the transformer and the two at the bottom, with a third which cannot be seen, are on the 15-kv. connections.



*Connections between transformer windings and pothead switches. Details of cable ground and jumper terminals shown at right*

Switching is effected by an insulated operating key, not shown in the accompanying halftone. The handle permits external operation.

The bushings at the left are hollow and contain the "bayonet" end of the switch-operating mechanism, into which the key fits and to which the jumper connections are made as shown in the connection diagrams. All the porcelain will withstand over 100 kv. as installed to allow kenotron tests to be applied to the cables. The arrangement shown for the neutral switch permits the disconnection of the transformer neutral from the ground and the application of a "high-potential or other test to the transformer windings, should advance in the company's testing program or the experience of the industry justify it." Testing of transmission cables is accomplished by opening the switches and connecting the high-potential test jumpers to the bayonets.

## *Electrolytic Production of Oxygen Proves Economical*

General Electric Company

| Comparative Data for 1,000-Cu.Ft.-per-Hour Oxygen Plant | Liquefaction Process | Electrolytic Process |
|---|---|---|
| Oxygen produced per kilowatt-hour (theoretical) | 25 cu.ft. | 5.29 cu.ft. |
| Oxygen produced per kilowatt-hour (actual) | 24 cu.ft. | 4.00 cu.ft. |
| Initial cost for producing equipment | $25,000 | $50,000 |
| Non-productive time required to get plant into full production | 2 to 8 hours | Almost instantly† |
| Number of hours per day plant must run to be most economical | 24 | Depends on type of cell |
| Rate of depreciation, per cent | 10 | 10 |
| Byproducts produced (theoretical) | 100 cu.ft. $N_2$ | 10.58 cu.ft. $H_2$ |
| Byproducts produced (actual) | 88 cu.ft. $N_2$ | 8.00 cu.ft. $H_2$ |
| Equipment area required, including aisles, etc. | 800 sq.ft. | 2,500 sq.ft.‡ |
| Ratio of labor cost per 1,000 cu.ft., per cent | 100 | 100 |
| Relative incidental material costs per 1,000 cu.ft., per cent | 100 | 90 |
| Relative maintenance costs per 1,000 cu.ft., per cent | 100 | 90 |
| Purity of oxygen, per cent | 99.0 | 99.5 |
| Purity of byproduct, per cent | 99.0 $N_2$ | 99.5 $H_2$ |
| Connected load for production only | 55 hp. approx. | 330 hp. approx. |
| Ratio of other costs per 1,000 cu.ft., per cent | 100 | 100 |

† A short time, together with an increased power consumption, is necessary to bring the electrolyte to normal operating temperature.

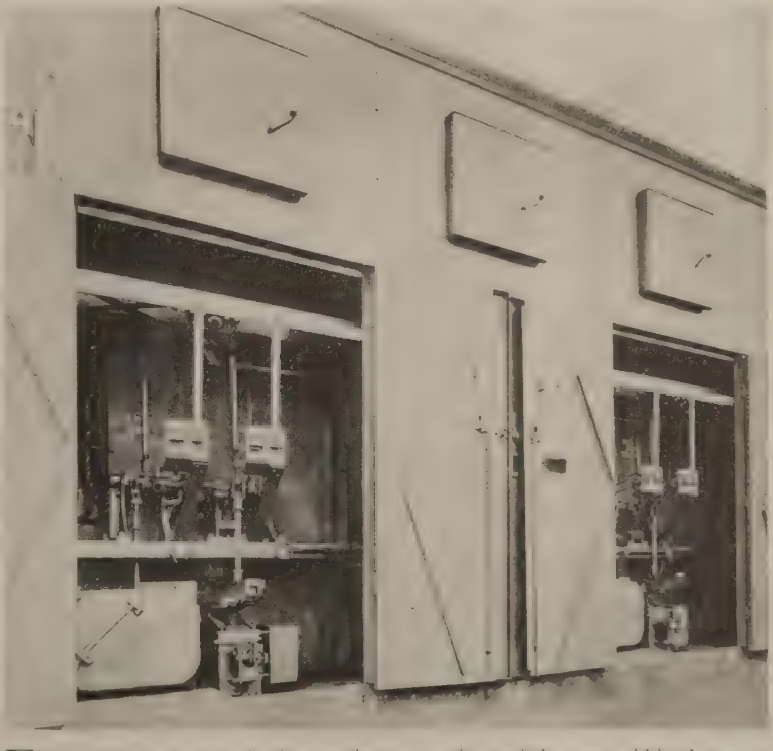
‡ Includes area for motor-generator sets. This varies with the type of cell, but a sacrifice in operating efficiency results if floor space is favored at the expense of other design features of the cell.

## Attracting New Industries by Utility Company Aid

VIGOROUS activity is under way in New England utility circles in the field of industrial development through central station co-operation with the New England Council, chambers of commerce and other organizations. The co-operating power committee of the electric service companies, headed by C. L. Edgar, has appointed a committee on industrial development under the chairmanship of Julius Daniels, assistant superintendent sales department, Boston Edison Company, which is rapidly becoming a factor in territorial industrial surveys and movements toward increasing such development. The other members of this committee are R. D. Morrison, industrial engineer Central Maine Power Company; A. R. Schiller, vice-president Public Service Company of New Hampshire; E. C. Hathaway, Twin State Gas & Electric Company, Boston (representing Vermont); P. J. Wilson, sales manager Narragansett Electric Company, Providence, R. I., and A. V. S. Lindsley, sales manager Connecticut Light & Power Company, Waterbury, Conn.

A number of New England power companies have established industrial development bureaus in their organizations and outlines for making industrial inventories have been sent to each company. Survey work is proceeding, contacts with chambers of commerce, co-operation with real estate agencies and railroads are being made, local business organizations are in many cases being advised of all bids sought by the United States government, air mail letters are being sent to prospective industrial concerns and advertising is being carried in trade papers emphasizing the power facilities of the territory. This work is in many cases being tied in with that of the power sales departments of the utilities, and at a recent meeting of the New England Association of Central Station Power Sales Engineers at Boston Chairman Daniels described the above industrial promotion work in considerable detail. The outline of an industrial survey sent to territorial operating companies includes eleven pages of form sheets.

## Outdoor Cabinets Used for Station Extension



EXISTING indoor switching equipment was amplified by outdoor additions at the Northwest station of the Commonwealth Edison Company, Chicago, Ill. The 12,000-volt buses and disconnecting switches are within the upper doors. Wheel-mounted circuit breakers and their operating mechanism are mounted below. Phase segregations on 50-ft. spacings are used.

# Exporter Reviews South American Market

### Large field calls for same selling methods as used in domestic market. American capital needed in South America's public utilities

By McKew Parr
*President Parr Electric Export Corporation*

VIRTUALLY all American electrical appliances may be sold in the South American market provided the same intelligence, patience and courage are displayed as are exercised in selling the same material in the domestic market. The greatest handicap to the development of the American electrical export business is the lack of familiarity and personal interest in these export markets by the directing heads of the smaller electrical companies. When the executives of the American electrical manufacturing companies show the same personal interest in foreign markets that is displayed by the German manufacturers, then, indeed, the future for the American electric export business will be very bright.

The standard practice of the lighting companies in South America is modeled after the practice of their home countries, most of their purchases being made in the country where the control of the stock is held and from which most of their engineers come. It is for this reason that all American electrical manufacturers are observing with sympathy and interest the activity of one of the large holding companies in the United States which has acquired a number of central-station properties in the smaller cities of South America, particularly in Brazil. When an American holding company secures an interest in a South American public utility company it means that American engineers and American wiring standards are introduced, the benefit of which accrues to all the manufacturers in general.

### Competition Is Chiefly National

In South America the competition very largely is along national lines, and consequently there should be no jealousy between American manufacturers in the foreign field, as the success of any one manufacturer in introducing American wiring practices results in a better opportunity for all other American manufacturers. No matter what the rivalry may be between companies in the United States, every American electrical man abroad is pleased and grateful to see another American electrical manufacturer secure business and advance American wiring practices.

A great source of help to the American electrical manufacturer visiting the South American market is found in the offices of the commercial attachés of the Department of Commerce, who are extremely accommodating and helpful to the salesmen of American manufacturers, their advice and information being of great practical value. Inasmuch as the steamship companies and cable companies of other nationalities all very properly do what they can to help the manufacturers of their own countries, American manufacturers should support similar services that have been built up by American capital.

It is very gratifying to observe the high estimate placed in South America upon the quality and dependability of American electrical material. The prices of American electrical materials are considerably higher than those of European manufacture, but it is my observation that in all cases it was felt that American electrical materials and practices were of the very best and, despite the much higher price, it appears to be the general opinion that the American product was worth the increased charge. It is my opinion that, despite the price handicap, our goods may be sold in all markets in very large volume by applying to their sale the same methods of missionary work and advertising that have been developed in marketing similar products in this country.

It is essential, in order to reap the greatest benefit from the possibilities that are open to American manufacturers in South America, that this country invest more freely in the securities of South America's public utilities. A study of the returns to stockholders in the United States who have invested in South American utilities proves that the field offers a very attractive return on the investment, with a high rate of security provided the management is trustworthy. By applying the experience and efficiency that we have gained in the operation of central-station business in this country we cannot help but meet with considerable success in South America.

### Recommends U. S. Investment in South America

It was the unanimous opinion of all Americans in South America with whom this subject was discussed that it would be very much more beneficial for the future of the United States to invest its capital in the utilities in Brazil and the Argentine Republic, Chile and Peru, instead of lending its capital, as at present, to the European financial agencies that support the manufacture and exportation of European electrical material to South America. It was the opinion of those consulted that the United States is simply lending its own gold to its competitors to use against us in this market.

The German electrical manufacturers have shown a great deal of interest in the South American market and have many branches, carrying large stocks, in all the important centers. In general, the German products are considered to be decidedly inferior to the American goods, although they are usable and workable. There are very few British electrical lines of wiring supplies to be found in South America with the possible exception of power cables. There is one Belgian manufacturer of motors, control apparatus and wire that has a very good business in Brazil. An Italian manufacturer of motors and of fans and another Italian maker of wires have branches throughout the various countries and do an excellent business. An Italian manufacturer of electric-heating appliances has a small sale in Brazil. The Italian interest in the electrical industry is very active throughout South America, many of the leading jobbers and contractors being Italian and several important central stations are of Italian ownership. A well-known Dutch manufacturer of lamps has an extremely large business, a Dutch manufacturer of wire has a fair business, and a French manufacturer of wire has a small business, mostly of annunciator and office wire. Electrical fixtures are manufactured both in Brazil and in the Argentine Republic by local firms which do a considerable business. There are two wire manufacturers in Brazil, both appearing to be prosperous.

In these countries there is a great lack of capital and an appreciation on the part of the educated classes of the necessity for development of the public utilities by

American or European capital. In Brazil the legal rate of interest is 12 per cent per annum, but the average merchant and business man have to pay considerably more. One can secure on time deposits in Brazil from the leading banks an interest rate of 9 per cent per annum, so it will be seen that the country offers a most excellent field for investment.

## Merchandising Methods of Berlin Electrical Company

PROGRESSIVE merchandising methods are not confined to the United States. In Berlin the Berliner Städtische Elektricitäts Werke Aktien Gesellschaft makes use of elaborate display rooms, newspaper advertising, illuminated dwelling houses, illuminated signs and catchy poster effects on the monthly bills. The influence of the latter was measurable by the large number of inquiries that came each month for the particular appliance then advertised. These appliances included sewing machine motors and sewing lamps, hot water accumulators, washing machines and vacuum cleaners. The same method was used for special publicity on the deferred-payment plan. In addition, a model of the company's new 300,000-kva. power plant was displayed at three exhibits held by various outside organizations during the past year.

To facilitate the wiring of homes and the purchase of appliances, the company made arrangements with a large number of contractors and dealers for financing the customers' orders.

For this purpose a separate organization was established. The customer pays a certain percentage down and signs an agreement with the company to pay the balance at the same time he pays his lighting bill. To cover overhead and interest a charge of 5 per cent is made for payments in five monthly installments or 10 per cent for ten months. Meanwhile, the company advances to the contractor or dealer the unpaid balance. The customer, of course, has the use of his purchase during the period of payment. With the traditions prevailing in Germany this is a radical innovation.

The company states that the plan is meeting with increasing favor and has found particular application for Christmas purchases. To assure the purchase only of articles coming up to accepted standards, the company maintains a testing laboratory. This is apparently in lieu of a nationally functioning organization for approving equipment and installations. The company also exercises supervision over the contractors, through a system of approvals which can be and in a number of cases have been withdrawn for cause. At the end of 1926 there were 2,850 approved contractors or contracting firms.

The company's progressive policy evidently pays. During 1926 the number of low-tension customers (presumably residential, commercial lighting and small power) increased from 368,706 to 442,044, a gain of almost 20 per cent. During the same period the corresponding connected load increased from 516,915 kw. to 555,698 kw. and the total connected load from 741,417 kw. to 801,203 kw.

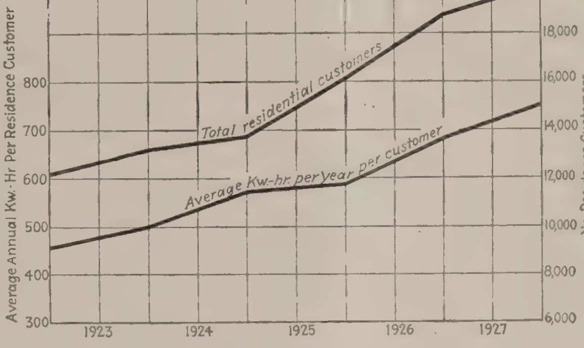
*Readily accessible appliance display stand and customers' lounge room also having equipment on display*

## Residential Customers Use 753 Kw.-Hr. per Year

By D. F. McCurrach

*Rate Engineer Northwestern Electric Company, Portland, Ore.*

EXCLUSIVE of electric water heating, residential customers on the system of the Northwestern Electric Company, Portland, Ore., used an average of 753 kw.-hr. each during 1927. If water heating is included the consumption was 946 kw.-hr. per customer. The number of residential customers and the average annual consumption per customer for the past five years are shown by the accompanying curves. This system embraces a considerable rural territory in southwestern Washington, which has a tendency to lower the average. The effect of adding a large number of rural customers



*Range sales contribute to increasing domestic consumption*

PRIMARY RATE FOR RESIDENCE LIGHTING COVERING FIRST 100 HOURS USE OF DEMAND

75 per cent of customers pay for first 20 kw.-hr. at primary rate and balance at secondary rate.

| | Cents Per Kw.-Hr. |
|---|---|
| First 9 kw.-hr. per month | 8 |
| Next 70 kw.-hr. per month | 7 |
| Next 100 kw.-hr. per month | 6 |
| Excess over 179 kw.-hr. per month | 5 |
| Secondary rate: | |
| First 50 kw.-hr. per month | 3 |
| All excess per month | 2 |

A discount of 5 per cent allowed for prompt payment.

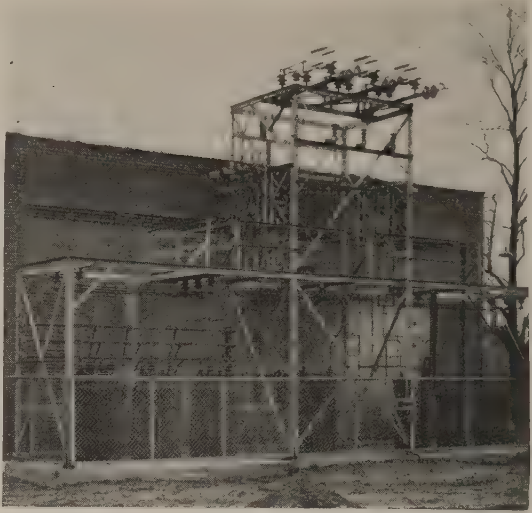
Minimum charge for lighting service only $1 per month.

Minimum charge for lighting service in combination with heating, cooking and small domestic power loads in excess of 2 kw. connected, $2 per month.

in 1925 is clearly shown by a rise in the customer curve and a drop in the consumption curve.

The gratifying increase shown in domestic consumption over the past five-year period is of particular interest in view of the fact that during this time the rates have not been changed and the showing made would seem to be an indication of their reasonableness, as the customer has seen fit to utilize this service in increasing quantities. Obviously, this would not have been the case if the cost of service had been found burdensome in any way, or had it represented a large percentage of the expense of maintaining his home. The principal element contributing to this increase is undoubtedly ranges, the saturation of which has increased from around 5 per cent in 1923 to approximately 20 per cent at the present time. Radio, home-lighting campaigns and appliance sales efforts also have contributed in a large measure to this upbuilding.

## A Multi-Voltage Industrial Substation



THIS industrial substation, through which the Fort Wayne, Ind., works of the Western Gas Construction Company, a subsidiary of the Koppers Company, is served by the Indiana Service Corporation, may be taken as a good example of modern construction and design. The incoming power is at 13,800 volts and serves secondary demands of 225 kva. at 4,000 volts, 450 kva. at 460 volts and 100-kva., single-phase for lighting at 115-230 volts. Provision is made in the design for primary metering equipment which has not yet been installed.

# *Electrical Industry Objects Only to Power Feature of Boulder Dam Bill*

*An Interview With*

R. H. BALLARD

*President Southern California Edison Company*

"NO PROPOSED legislation in recent years has attracted more attention or has been more involved in politics that the Swing-Johnson bill to provide governmental flood control and power development on the Colorado River. Failure of the bill to pass has been laid partly at the door of the privately operated utilities of the nation and partly to opposition of the basin states, notably Arizona. It is the proposal to put the government into the power business and the unjust accusation made against the light and power utilities of blocking the bill that concern me and upon which I feel strongly," declared R. H. Ballard, president of the Southern California Edison Company to a representative of the ELECTRICAL WORLD recently.

"One point should be made clear to the ardent supporters of the Boulder Dam bill, and that is that the electrical industry and business interests of the nation oppose on principle all schemes which would put the government into business and do object most emphatically to the provision still retained in the bill authorizing the government to build and operate power plants at Boulder Dam in violation of the policy laid down in the federal water-power act passed by Congress in 1920, after more than ten years of deliberation.

"If the bill should be amended to remove this objection it would still provide the benefits sought for and permit repayment of the cost of the dam to the government. It could also provide that the government construct the dam and that the power development be made under the provisions of the national law and be subject to regulation by the Federal Power Commission. Any agency — municipal or corporate—desiring to develop power at the dam could then apply to the Federal Power Commission for a license to do so. Moreover, the bill in its amended form would no doubt prove less objectionable to Arizona and Nevada, which have insisted that they receive revenue from power equivalent to the taxes they would otherwise receive if power development was carried out by private capital."

# Fixed Par Versus No-Par Stock

### Practice is divided between two systems of issuing stock. Massachusetts considers legalizing the issue of shares without par

HAS the issue of no-par stock become an established institution in public utility finance? The question is again brought forward by the introduction of a bill in the Massachusetts Legislature providing for the legalization of the practice. Massachusetts early introduced legislation prohibiting the use of no-par stocks and has been more or less a leader among those states where no-par stock is prohibited.

Practice in respect to par is divided. Its use in the United States was recommended in 1911 in a report to Congress by the Railroad Securities Commission, generally called the Hadley Commission. It was first introduced in New York State in 1912. No-par stock is now permitted, in so far as common shares are concerned, in about three-fourths of the states, and preferred shares without par value may be issued in approximately half of the states. In some of the states there are further restrictions upon such issue in the case of public utilities. Last year power and light financing in the United States involved a total of about $150,000,000 in the form of common stock, and the bulk of this was issued in shares without par value. Furthermore, a large proportion of preferred stock has recently been issued in no-par shares. Legislative changes have been instituted in several of the states to facilitate the issuance of stock without par value.

That there are two sides to the question is emphasized by the recent attack of a leading economist upon the issue of no-par stock. In "Wall Street and Main Street" Prof. W. Z. Ripley referred to the issue of no-par stock as "an egregious malversation of the rights of shareholders and of the public generally." He states, further, that no-par stock "widens the opportunity for resort to setting up a so-called initial surplus upon the creation of a corporation, and that it distinctly tends to enhance the danger of misrepresentation of expected dividends." Elsewhere he adds: "Is it not obvious that the absolute and uncontrolled power afforded to those new charters to fix the price of each new issue of shares independently of all others reduces the whole matter to the merest gamble on the integrity and judgment of the corporate officers and directors? Most of all, is it not feared that this no-par device is utterly unsuited to all public service companies wherein by all the principles of sound regulation the issue of securities ought not to exceed the actual amount of the investment? Inasmuch as the issuance of no-par shares cuts the ground from under any attempt to correlate closely the amount of the investment and to save its par value for the securities, it is clear that regulation and non-par shares are utterly incompatible one with another."

> Professor Ripley: *The issue of no-par stock is an egregious malversation of the rights of shareholders and of the public generally.*
>
> Hadley Commission: *We do not believe that the retention of the hundred-dollar mark, or any other dollar mark, on the face of the share of stock is of essential importance. We are ready to recommend that the law should encourage the creation of companies whose shares have no par value, and permit existing companies to change their stock into shares without par value.*

### Specific Objections to No-Par Stock

Apart from the statements just quoted with respect to no-par stocks, any opposition or criticism which exists appears to be based on technical or practical phases of the question. Certain accounting complications arise in connection with no-par stock, especially with respect to the balance sheet, and a uniform solution is still lacking.

It was brought out in the Hadley Railroad Securities Commission's report in 1911 that no-par stock permits inflation by making it easy to create an excessive number of shares. The same report raises the point that no-par stock divides companies into two classes, those having par value shares and those having no-par value shares, and that this creates confusion. In some states the authorities have refused licenses to form corporations because the non-par feature involves the compilation of fees which have been fixed by statute on the basis of the par value. It was stated that transfer fees, stock taxes, fees for operation in foreign states, etc., may be based upon arbitrary figures in excess of the fair value of the stock. The argument also has been advanced that relieving the stockholders from discount creates an unfair liability to creditors.

After considering the matter from every angle, however, the commission decided: "We do not believe that the retention of the hundred-dollar mark, or any other dollar mark, on the face of the share of stock is of essential importance. We are ready to recommend that the law should encourage the creation of companies whose shares have no par value and permit existing companies to change their stock into shares without par value whenever their convenience requires it. After such conversion, any new shares could be sold at such price as was deemed desirable by the board of directors with the requirement of publicity as to the proceeds of the sale of such shares and as to the disposition thereof, giving to the old shareholders, except in some cases of reorganization or consolidation, prior rights to subscribe pro rata, if they so desired, in proportion to the amount of their holdings."

The commission, moreover, goes on to point out that there are outstanding advantages in the issue of no-par stock where two companies whose shares have different market values consolidate. "It has been the custom to equalize the difference by the issue of extra shares of the consolidated company to the owners of the higher priced stock. This practice has always tended to produce increase of capital issues and may readily cause the new stock to be issued for a consideration less than its par value. The only alternative was to scale down some of the old stocks, and this often involved serious difficulties, both of business policy and of law. By the simple expedient of omitting the dollar mark from the new shares, the number can be adjusted to the demands of financial convenience without danger of misrepresentation or suspicion of unfairness to any one."

In the case of reorganizations the advantage of shares without par value is even more obvious. Says the commission's report: "It is here that the necessity and justice of getting money from stockholders is greatest. It is here that the impossibility of getting them to pay par for new shares is most conspicuous. We believe that in such cases the public interest would be subserved and the speedy rehabilitation of the roads promoted, by requiring the conversion of common stock and encouraging the conversion of the preferred stock into shares without par value, the certificates simply indicating the proportionate or preferential claims of the holders upon assets and upon such profits as might from time to time be earned." While the discussion is dealing with the railroads rather than the power and light situation, it is obvious that the principles apply equally in the latter case.

### Advantages of No-Par Stock

Advocates of no-par value shares maintain that their cardinal merit is accuracy. Par value printed on a share of stock, it is urged, is not necessarily a true indication of its real value. Its value obviously depends on the corporation's net earnings and assets both past and future, rather than on the figures printed on the certificate. Basically, a stock certificate is nothing more or less than a statement of ownership of a proportionate share of the assets of some business or organization. It is probable, say its advocates, that the statement of an artificial par value of such share is capable of producing much more misunderstanding than the share without par value. Naturally, shares of stock find their natural level, as with any other species of property, in an open market, and the purchaser or holder is not deceived by any false or fictitious face value of his certificate. It would not be difficult to obtain innumerable examples of shares in mining and similar ventures with a nominal value of $100, but which actually are worthless or nearly so. Par value printed on a certificate makes it easy for promoters to extract money through the irresistible attractiveness of offering a $100 share of stock for $50.

Possibly the strongest argument put forth by advocates of no-par stock is that already mentioned by the Hadley Commission, that the method simplifies consolidation and reorganization. When the par value of a stock is not fixed the number of shares can be readily adjusted to the demands of financial convenience, thus affording relief from an undue inflexibility of financial set-up. This is a matter of decided importance in view of the large number of capital reorganizations in the power and light industry at the moment.

Another argument put forth by advocates of no-par stock is that the incentive for the over-valuation of assets in order to balance the books at the time of reorganization is reduced. Properties can be placed on books at a fair value and capital stock can be credited at the same value. In this way promoters are deprived of the advantage of inflated capitalization and the attention of the investing public is focused upon the real value of the shares. This discourages the carrying of fictitious values in balance sheets of good will, patents and the like, and in an effective way, without delaying or embarrassing legitimate enterprises, carries out the purposes of the so-called blue sky laws. Again, if there is no par there can be no discount, so the stockholder is relieved of the liability for discount resulting from purchase of stock at less than par.

The opposition to no-par stock in Massachusetts is rather a long story and one based on financial principles which have been adopted in New England for many decades. In arguing for the passage of the bill, counsel for the Electric and Gas Association stated that "If the gas and electric companies had no-par value stock, the half-truths which have brought so much ill will to utilities in Massachusetts would be forestalled. The habit of the general public in quoting utilities as obtaining large dividends should be quoted on the par value plus the premium actually paid in by the shareholder."

## Oil Well Pumping with Electricity

IN SPEAKING to the convention of the Oklahoma Utilities Association, O. A. Jennings of the Oklahoma Gas & Electric Company presented twelve specific reasons why beam pumping of oil wells is better performed with electricity than with other forms of power. Since his company took on about 36,000 kw. of oil field load in 1927 it seems that Mr. Jennings should speak with adequate authority. The twelve reasons, all of them contributing to lowered cost and increased production, are:

1. Power shutdowns for repairs to prime movers.
2. Easier on belts and rig, which results in less time down for breakage and repairs.
3. Actual experience shows rods unscrew less often and break less often because of the more even and steady motion of the beam.
4. Regular, even motion and exact number of pumping strokes per minute of pumping time means more oil lifted.
5. Fewer rod jobs and lost motion due to shutdown time.
6. Even motion of beam means less "whipping" or "spring" of rods in deep holes.
7. Less time for complete pulling job. No sticking on center, no stalling of back-firing, no clutch troubles. Not necessary for one of the well gang to be making frequent trips to engine house to kick off engine. All men on "derrick floor"; that is, "on the job all the time."
8. Not affected by freezing of water lines, water in gas lines, low steam pressure, poor mixture in cold weather or too rich mixture in hot weather.
9. Ring oil bearings do away with the necessity of daily oiling and the attendant danger from neglect of this duty.
10. Fire risk loss—insurance, both fire and compensation, lower in electrically equipped plants.
11. Impossible for motor to run away, no exploding flywheels, no torn-up rigs.
12. Salvage value of equipment higher than any other oil field power equipment.

The electrical equipment for beam well pumping consists of a double-rated motor in capacities of 10/25-15/30 and 30/65 hp., the lower rating used for pumping, the higher rating for pulling out the rods and tubing when the wells sand up or other troubles occur. This equipment is carried in stock by manufacturers and many oil companies keep extra motors in their warehouses.

# Portable Lamps Increase Revenue

By M. Luckiesh
*Director Lighting Research Laboratory, National Lamp Works, Cleveland, Ohio*

THE present rate at which portable lamps are being bought is approximately 0.3 unit per home per year, representing an average expenditure of about $3.60 per customer per year. Six additional portable lamps can readily be justified in the average home. The lighting equipment for a "conservative ideal" home, based on the minimum requirements for utilitarian and convenient lighting, includes an average of 8.5 portable lamps. Bedrooms account for 2.5 portables. The remaining six are distributed elsewhere. However, extensive surveys indicate that there is an average of only 2.8 portable lamps per home. Considering the present wired homes, therefore, six additional portables would make a potential market for more than 100,000,000 portables, or sixteen times as many as were sold last year.

The portable lamps in use in the home account for at least 49,000,000 sockets. The existing potential market, however, would require a possible addition of at least 100,000,000 sockets, an equivalent of 5,000,000 new residential customers. Five million new residential customers is greater than the number added to central-station lines in the past three years and is nearly one-third of the total number of residential customers in this country.

A 200-watt, direct-indirect, portable operating one hour per day (average socket) increases the average annual gross revenue $5.08. Five small portables containing 50 watts each, burning one hour per day, would increase the average annual gross revenue $6.36. The addition of these six portables, one direct-indirect and five small portables, would alone increase the average annual gross revenue per residential customer from $27.89 to $39.33, or 41 per cent. As long as rates remain unchanged much of this increase in gross revenue is really increase in net revenue.

Portable lamps may provide proper and convenient lighting and add much to the cheerfulness of the home. The portable also earns its keep when not lighted because of its decorative value. Furthermore, it is one piece of lighting equipment which is quite often lighted purely for the charm or decorative note which it introduces in the home.

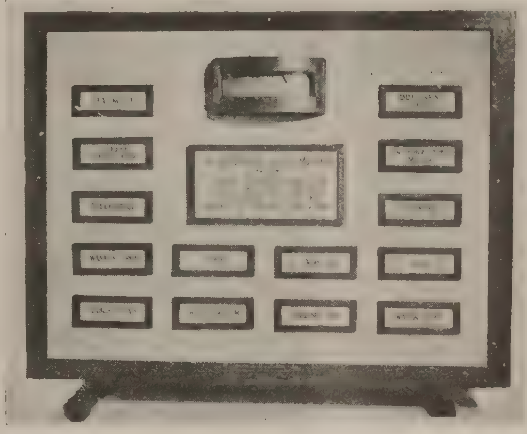
# Selling Electric Refrigeration

THE electric refrigeration committee of the National Electric Light Association has recently issued a booklet constituting a general outline of suggested year-round sales and merchandising activities. "Selling the 'Idea' of Electric Refrigeration" is offered as an aid for a more intensive and more effective marketing of electric refrigeration. The activity proposes a co-operative market development effort, bringing together the local electric refrigeration interests, the electric light and power companies, the electric dealers and contractor-dealers, department, hardware, housefurnishing, dry goods, general stores and other distribution channels.

By way of practical illustration the mailing pieces and advertisements now being used by an electric light and power company that is said to have made marked progress in the building of an electric refrigeration load are shown. These items are personalized in each case with the name of the individual electric customer. It is especially pointed out that in this or in any other direct mail campaign a list of prospects should be very carefully selected and prepared. It is stated further that this or any other advertising activity cannot be expected to produce sales unless the utility and other refrigeration dealers carefully plan ahead and follow through with a well-organized personal solicitation. This co-operative plan is not offered as a substitute for the activity of manufacturers, but is designed to pave the way by selling the idea of refrigeration without any reference to particular makes or types.

# Appliance-Use Cost Meter

THE cost of energy consumed by various appliances and devices is a matter of moment to all electric service users and it is particularly of interest to those customers, present and prospective, on rural and farm lines. The obvious reason for this interest among rural users is that it is necessary for this class to make large use of energy for other than lighting alone in order to benefit fully from the service and to make the supply of that service at least not unprofitable to the utility. The engineering department of Iowa State College devised a display arrangement which shows in cents the costs of using various appliances and equipments at a rate of 10 cents per kilowatt-hour. This display was set up under the direction of Prof. Frank D. Paine of the department, who is also director of the Iowa rural electrification project.



*Meter at top of board successively shows cost of operating each device indicated in panels*

The operation of the display is simple. It consists essentially, as shown in the illustration, of a board on which is mounted an indicating wattmeter calibrated in cents per hour and a number of plates which are illuminated in turn to identify the appliances as they are turned on and off by a flasher.

The display was made up originally to serve as the exhibit of the rural electrification project at the convention of the Iowa Farm Bureau Federation. At this convention the display was seen by more than 3,000 farmers and farmers' wives of the state, in whom it excited much interest. Following the convention the exhibit has been in continuous use by utility companies throughout the state on loan from the college.

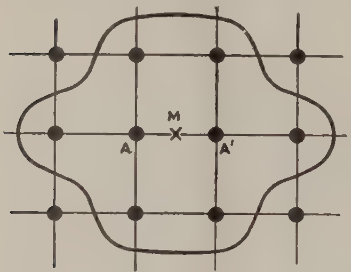
## *Motor Starting Current Vs. Lighting Flicker*

*To the Editor of the* Electrical World:

In a study of the effect of motor starting currents on the voltage of a combined light and power underground alternating-current network it is essential, as in all engineering studies, that careful consideration be given to the factors from which mathematical conclusions are drawn. H. L. Wallau, in his article "Motor Starting Current Vs. Lighting Flicker," in the Electrical World of Jan. 28, 1928, has set up certain derived formulas from which he would determine the allowable ratings of motors to be installed on a network. Let us examine some of the factors used in deriving the formulas:

(a) One-Way Feed.—This is rather unusual but it is assumed that Mr. Wallau refers to a motor installation somewhat isolated from the network proper. It is hardly conceivable, however, that it would be so isolated as to have only one transformer bank as a source of current. One bank may be considerably closer to the motor installation than several others, but this does not justify the assumption that all the other banks may be neglected in calculations of current fed to the motor. This is especially true when the network transformers have high inherent impedances, as is generally the case.



*Motor starting current on underground a.c. network comes from more than two banks of transformers*

(b) Two-Way Feed.—The same reasoning applies here as was noted above for a one-way feed. Transformers located at distances further than one-half block from the motor must also be taken into account. This may be shown by the case indicated by the accompanying sketch, in which we have a networked section with 100-kva. transformers uniformly spaced and with 400-ft. blocks and a three-phase motor installation at *M*. The motor location which will result in the greatest voltage disturbance in its immediate vicinity is evidently in the center of the block, as shown. The motor current will be split up among the surrounding banks. However, since the average network system may not be as "stiff" as this one, only the transformer banks within 1½ blocks from the motor, as the boundary line on the sketch indicates, are included in the computations.

The combined cable and transformer impedances from all the included transformer banks to the motor *M* will be 0.0076 ohm (resistance 0.00303 ohm, reactance 0.00696 ohm), assuming 10 per cent transformer impedance and three 500-circ.mil single-conductor cables in one duct. The circuit impedance from the banks *A* and $A^1$ to *M*, which alone is considered by Mr. Wallau, will be 0.0116 ohm, about 50 per cent higher than that obtained by considering the six other banks. If banks farther away were also taken into account the discrepancy would be larger. It is apparent that the motor size as determined by Mr. Wallau's formulas would be smaller than would be actually allowable.

Mr. Wallau has given a value of 15 per cent as the average power factor or the starting current of induction motors. It is believed that he was referring only to squirrel-cage induction motors when he gave this figure, if such is correct. The wound-rotor, slip-ring type of motor using a resistance starter will have a much better starting power factor.

The ratio of resistance to reactance for the circuit will determine the influence of the motor power factor in the regulation of the circuit. It so happens that in the example noted above this ratio is such that motor power factor does not bear an important part. Thus the allowable motor starting current increment for two volts regulation is 270 amp. for 15 per cent power factor, 260 amp. for 50 per cent power factor, and 300 amp. for 80 per cent power factor.

No attempt should be made to calculate an allowable motor starting current without taking fully into account the actual physical layout of the network system, the type of motor and the motor starter. After a value has been determined it is not necessarily the maximum allowable starting current for the motor. It represents an instantaneous value and must be used on a rate basis. For instance, if 200 amp. will produce a two-volt drop, a motor might have a maximum starting current value of 600 amp. and still not produce an objectionable light flicker provided the 600 amp. are obtained at a definite time rate and not instantly. That is, if a change in voltage at the rate of two volts per second is not objectionable, then the allowable motor starting current can be any amount so long as the rate of increase is not greater than this value.

## *Time Lag of Spark Gaps*

*To the Editor of the* Electrical World:

I have just read one of the editorials in the March 17 issue of the Electrical World, entitled "Time Lag of Spark Gaps," commenting on the work done by J. J. Torok of the Westinghouse company. I feel that the last part of paragraph three of this editorial may be misconstrued and the impression may be conveyed that the sphere gap is not satisfactory as a measuring instrument for high voltages. The actual facts are that this work of Mr. Torok's has demonstrated that while the sphere gap has a time lag which depends upon the steepness of wave front of the surges impressed on it, this time lag is so small that even with the very steepest wave fronts that can be obtained in the laboratory the impulse ratio will probably not be more than 10 per cent and with the steepest wave fronts that have been observed due to lightning the impulse ratio will not be more than 5 per cent.

In fact, Mr. Torok's work indicates that the sphere gap may be considered quite reliable for all practical purposes, though it could hardly be classed as a precision instrument. However, one advantage that we shall gain as a result of Mr. Torok's work will be a better insight into the behavior of the sphere gap during the breakdown period, and as a result we shall no doubt be able to make better use of it as a measuring instrument than we have done in the past.

Charles Fortescue,
Consulting Transmission Engineer.
Westinghouse Electric & Manufacturing Company.

# Digest of Electrical Literature

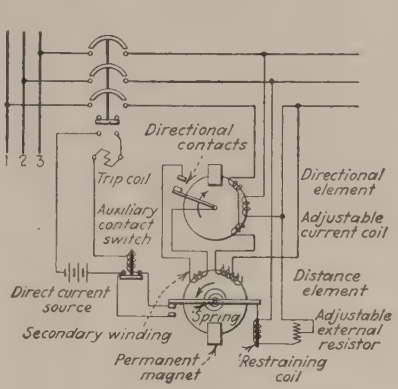
## *Hydro-Electric Development and Steam Equipment*

*Binary Mixtures in Steam Engineering.*—When mixtures of two substances, particularly those having different boiling temperatures, are subjected to the action of temperature and pressure, their behavior is contrary to that encountered with simple substances, such as water. Ebullition and condensation temperatures vary under constant pressure and new heat cycles and characteristic curves descriptive of them are involved. This discussion includes references to a number of articles appearing in foreign publications and referring to the theoretical and practical considerations of binary mixtures under thermodynamic and border-line conditions. It is stated that cyclic processes involving binary mixtures are of great economic significance when applied to steam engines. The effort to produce higher efficiency leads to an increase in the boiler pressure, but even at the highest technically permissible pressures the evaporation temperature is still far below the limit permissible by the strength of the materials employed. This leads to the employment of binary vapor engines wherein, for example, mercury is used in the upper temperature range and water in the lower. It is contended that the same end may be attained by using a solution as a working medium. The heat is supplied to the evaporator at the highest permissible temperature, while the heat in the mixer is liberated at a temperature which is suitable for the upper range in the heat cycle of the conventional steam engine. The steam generated in the evaporator then performs work in a steam engine against the mixer pressure and is afterward exhausted to the mixer.—*Mechanical Engineering*, April, 1928.

## *Units, Measurements and Instruments*

*The Testing of Audio-frequency Transformers by Means of the Cathode Ray Oscillograph.*—M. Kobayashi.—The cathode-ray oscillograph may, in the opinion of the author, be applied to the determination of the characteristics of apparatus used within a wide range of frequency. The application to the testing of audio-frequency transformers is described and the impedance-frequency characteristics and voltage-frequency characteristics are obtained vectorially from the elliptical figure produced by the cathode-ray oscillograph. The author has made several observations in connection with such test work, including: The impedance and voltage ratios are not constant for all frequencies and, in general, separate resonant frequencies exist for impedance and voltage ratios; if a suitable non-inductive resistance is connected to the secondary of the transformer the impedance and voltage ratio are stabilized against frequency variation; it is desirable in the design of the transformer-coupled amplifier that the secondary be shunted by a certain non-inductive resistance, and the transformer coupling should not be applied to the amplifiers for which phase distortions are undesirable.—*Journal of the Institute of Electrical Engineers of Japan*, February, 1928.

*The Impedance Relay.*—H. A. McLaughlin and E. O. Erickson.—The developments made in the impedance relay since its introduction in 1923 are reviewed by the author. The features of construction and operation, with special emphasis on the methods of obtaining proper potential for the restraining elements without the use of high-voltage potential transformers, are also noted. The use of potential form condenser type bushings is discussed, and the methods of compensating for the voltage drop through power transformers and for the shifting of the secondary neutral point have been developed in connection with the use of low voltage potential. The authors state that the impedance relay, while relatively new in the field of protective devices, is already being used extensively both in this country and abroad. Because of the impossibility of obtaining satisfactory results with over-current and directional relays in some cases, and the objectional time delays involved even when selectivity can be obtained, the impedance relay is receiving more and more consideration. This is stated to be a step in the right direction, since the impedance principle involves a relay independent of system conditions and dependent on direction of current flow for its operation and on distance from the fault for its time. Many improvements and developments have been made as the result of operating experience which has resulted in a better understanding of the operation of this device.—*Journal of the American Institute of Electrical Engineers*, April, 1928.



*Directional-control impedance relay*

## *Transmission, Substations and Distribution*

*A General Solution for Short Transmission Lines.*—C. M. Longbottom.—The author has endeavored to describe a general solution by which voltage regulation may be ascertained quickly and with reasonable accuracy. The basis of this method is the circle diagram and formulas and charts are given to illustrate the contention and aid in the solution of problems. The effect of the length of line, the line-phase angle, the load power factor, the regulation of a short line, and regulated and unregulated line values are given. A tabulated card index for certain standard conductor sizes is offered and suggested for ready reference in correlating the values of the several factors involved.—*Electrical Engineer (Australia)*, Feb. 16, 1928.

*Safety Interlock for High-Voltage Apparatus.* — M. Jumier. — It is customary to provide inclosing doors for cells in high-voltage indoor power installations, to prevent access to live parts. An arrangement is described in this article by which all such doors may be closed by locks operated by a master key. The latter may be kept in a small metal box, located near the main oil switch. This box has a hinged cover, which cannot be opened until the oil switch has been tripped. Only then is it possible to obtain the key and unlock the doors to the various cells, which are now dead. On the other hand, the oil switch cannot be closed until every cell door has been closed again, the key has been returned into the box and the lid of the box has been shut. In addition, red and green signal lamps are connected to all doors and the contact in the box, to show the attendant optically the position of doors and the main switch. This is claimed to be the most foolproof safety interlock known.—*Revue Générale de l'Electricité*, March 3, 1928.

*Three-Winding Transformer Banks.*—G. D. Floyd.—Operating features of three-winding transformer banks have been considered by the author. A theoretical study of simple cases of parallel operation of typical transformer banks is included, showing the effect of various methods of operation on the maximum load that can be carried on the windings and the consequent reduction in transformer bank capacity. Some generalized conclusions are drawn from a study of load unbalancing and parallel operation; a three-winding transformer where load is taken from both secondary and tertiary including parallel operation of secondary and tertiary windings is essential for equal division of loads among the transformers; the utilization of available capacity becomes greater as the number of banks increases, other things being equal; it is desirable, from a utilization standpoint, to be able to divide the 110-kv. bus into sub-systems; if one or more tertiary groups of feeders are lightly loaded and the others relatively heavily loaded, better utilization of available capacity can be made by supplying the lightly loaded group over the reactor bus, and opening the tertiary supply from its transformer bank, and the voltages on the tertiary group of feeders are not materially different for considerable unbalance in tertiary loads. —*Electrical News (Toronto)*, April 1, 1928.

## *Illumination*

*Lighting Spray Booths.*—A. H. Nuckolls.—As a result of an investigation to determine the most desirable method of safeguarding the electric lighting arrangements for spray booths several practices have been developed. It is stated that in such work there are two distinct phases of fire hazard to consider, the volatile liquid solvents, the vapors in admixture with the air being flammable, and the non-volatile solids or residue, which are flammable and easily ignited under moderate heat. The residue and vapors when present in the air as a mist or cloud may, under certain conditions where there is a source of ignition, offer a flash fire or explosion hazard. In order to obtain information regarding the dangers involved, a series of measurements were obtained of maximum temperature of various parts of vapor-proof and mercury vapor lamps, fixtures and auxiliaries by means of accurately calibrated thermocouples. A series of tests to determine the surface temperatures likely to cause ignition of spray residues such as are commonly used was also made. A series of spray tests in which the spray was applied directly to the lighted lamps, fixtures and auxiliaries while in operation was carried out. The result as indicated in temperature readings at various points on standard fixtures is offered in condensed form.—*Laboratories' Data (National Board of Fire Underwriters)*, March, 1928.

## *Motors and Control*

*The Three-Phase Compensated Induction Motor.*—Toshio Sugie.—The various advantages and relative merits of the several types of induction motors and of a compensated machine of this type are compared by the author. The theory of the compensated induction motor is described and the best results with respect to the load characteristics with various brush positions and the effect of voltage variations and of frequency variations, as obtained with a test machine, are considered. It is stated that though the motor has a limitation of maximum possible capacity so far as design considerations are concerned, there is no obstacle due to this limitation with the motor capacities ordinarily used for industrial purposes. This device is said to possess speed characteristics and starting characteristics comparable to those of a wound-rotor induction motor and to incorporate a series compensation comparable in dependability to that obtained with parallel compensation. The primary windings are arranged in the stator and the construction is stated as being simplified. The power factor approximates 90 per cent.—*Journal Institute of Electrical Engineers of Japan*, February, 1928.

## *Heat Applications and Material Handling*

*Railroad Bridge Made by Arc Welding.*—A. G. Bissell. What is said to be the first all-welded bridge to carry rail traffic has recently been completed in Pennsylvania. The details of design and the fabrication procedure have been outlined by the author and the data for material and labor requirements are included. A series of tests were conducted upon this structure to determine deflection and vibration by running a locomotive across the bridge at various speeds.—*Iron Age*, April 12, 1928.

## *Electrophysics, Electrochemistry and Batteries*

*The Effect of Impurities and Moisture upon the Breakdown Voltage of Transformer Oil.*—Y. Toriyama.—The voltage-current curves of various transformer oils have been derived by the author from the breakdown value when using sphere and plate electrodes. It is stated that the results indicate that the curves are influenced not only by the form of the electrode but by the existence of dust and moisture in the oil. The combined effect of fibrous dust and moisture upon the breakdown voltage under uniform stress is given particular consideration, with particular reference to the former impurity. It is stated that in well-filtered oil this fibrous dust is very thin, and it has been assumed to be of ellipsoidal shape. On the basis of this assumption, the breakdown voltage of the transformer oil has been calculated, and the results are said to correspond closely to theoretical considerations.—*Journal Institute of Electrical Engineers of Japan*, January, 1928.

*Extreme Ultra-Violet Spectra Excited by Controlled Electron Impacts.*—K. T. Compton and J. C. Boyce.—This investigation is the outgrowth of an unsuccessful attempt to photograph, by ordinary spectroscopic methods, the spectrum of soft X-rays excited in solid targets by the impacts of electrons whose energies are of the order of 100 volts. Numerous experimenters have detected such radiation by photo-electric means, and the desirability of securing a direct spectroscopic check on the interpretation of the breaks found in their curves of photo-electric current versus bombarding voltage was evident. A modification of the original apparatus designed for use in the study of gases under somewhat different conditions from those hitherto employed permitted the desired determination. In this instance gas molecules have been substituted for the solid target previously used and conditions so adjusted that all radiation from them arises from single impacts by electrons of known and controlled velocity. It is stated that the gases have also been handled in such a manner as to insure such a high degree of purity that there is little room for doubt regarding the origin of the lines appearing in the spectrum. The apparatus used in this determination and the spectrograph light source and the method of handling the gases are given in detail. Data regarding the spectra of helium and neon and argon are included.—*Journal of the Franklin Institute*, April, 1928.

## *Miscellaneous*

*A New Method of Separating the Hydraulic Losses in a Centrifugal Pump.*—Michael D. Aisenstein.—Particulars of a method by means of which the friction and shock losses of a given pump may be determined separately from its head-capacity curve. The author has concluded his mathematical discussion and derivation of formulas with the analysis of a specific problem in design. A consideration has been offered of the apparently inconsistent expression for hydraulic efficiency which often amounts to less than the actual pump efficiency. The latter includes, besides hydraulic losses, mechanical losses such as disk friction, friction in stuffing boxes, etc. The reason for this inconsistency is said to repose in the fact that the theoretical head in feet for an impeller with an infinite number of vanes is never produced by the impeller and is an imaginary quantity because the average actual angle between the relative velocity and peripheral velocity is always less than the casting angle of the vane, so that the drop between the theoretical head in feet for an impeller with an infinite number of vanes and the theoretical head in feet for an impeller with a finite number of vanes does not consume any power and is not a loss.—*Transactions of the American Society of Mechanical Engineers*, January-April, 1928.

*Physical Properties of Lead Cable Sheaths.*—P. Dunsheath.—The author has discussed some of the troubles that may arise from the practical use of lead cable sheaths owing to physical weaknesses in the materials utilized and has indicated how these weaknesses are connected with the inherent grain structure in the metal and the streamline structure due to the extrusion process. Existing metallurgical knowledge is reviewed and illustrations are given from the author's investigation into the crystal structure of cable sheaths. Various factors involved in the much-discussed disintegration by vibration theory are examined and the improvement of pure lead by the employment of alloying metals is treated both theoretically and practically. Special apparatus for the vibration tests is described and a consideration of the "weld" and a description of a new type of cable press which produces a cable sheath that is weldless are also noted.—*Journal of the Institution of Electrical Engineers (England)*, March, 1928.

# News of the Industry

## Flood-Control Bill Appropriates $352,500,000

The Jones-Reid flood-control bill, carrying provisions which critics of the measure assert involve a total expenditure far beyond a billion dollars, was passed by the House of Representatives this week by a vote of 254 to 91. It had previously passed the Senate by 70 to 0. A possible presidential veto confronts it.

The bill authorizes appropriation of $325,000,000 for flood control works on the Mississippi, provides $17,500,000 in addition for flood control on the Sacramento River in California, and also makes available the unexpended balance of $10,000,000 previously authorized for survey of reservoirs on tributaries of the Mississippi. A planning board to be made up of the chief of the army Corps of Engineers, the head of the Mississippi River Commission and a civilian engineer is charged with the duty of reporting to the Executive before any definite plan of control is carried forward. The federal government is protected against damages to public utilities, which leaves them at liberty to sue for loss in accordance with their constitutional rights.

## Bay State Speaker Against Hasty Action

Speaker John C. Hull of the Massachusetts House of Representatives, at a hearing Wednesday before the joint rules committee, opposed action looking toward further public utility legislation in the Bay State pending a decision by the courts in the Worcester rate case. The committee was considering the resolve for an investigation of ways and means for further regulation of gas and electric utilities in the state. The Mayors of Cambridge, Somerville, Brockton, Lowell, Marlboro, Revere and Lawrence favored the resolve. Senator Gaspar G. Bacon, chairman of the committee on power and light, also declared that the proposed investigation should wait on the Worcester case.

## Lackawanna Road Has 76-Mile Electrification Plans

Coming electrification in New Jersey by the Delaware, Lackawanna & Western Railroad will, according to an announcement made by President J. M. Davis this week, include the Morris & Essex line from Hoboken to Dover, the Passaic & Delaware to Gladstone and the Montclair branch—a total of 76 miles of road or 173 miles of track, at an expenditure of approximately $14,000,000. Mr. Davis added:

"Officials of the company are carefully weighing the advantages and relative cost of purchasing electric power from outside companies as compared with the construction of a generating plant and manufacturing its own power. The construction and equipment of the proper power plant and accessories would cost about $4,250,000 and would raise the total cost of this electrification work to the neighborhood of $18,000,000. Construction work will be started just as soon as the Lackawanna engineers can prepare plans, and it is estimated that it will be completed within two years."

Jackson & Moreland of Boston have been appointed engineers to carry out the railroad company's plans, and it is probable that orders for all equipment will be placed within sixty days.

## Trade Commission Looks Into Propaganda

### Expenditures of Joint Committee of National Utility Associations Subject of Inquiry—Income of N.E.L.A. Also Put on Federal Body's Record

PAYMENT of substantial counsel fees to former Senator Irvine L. Lenroot of Wisconsin and Richard Washburn Child, former Ambassador to Italy, by the Joint Committee of National Utility Associations was revealed on Tuesday, April 24, at the Federal Trade Commission's investigation into public utilities.

Particulars of these payments were contained in the testimony of Ira L. Grimshaw of New York, assistant director of the joint committee. He said that Mr. Lenroot received $20,000 to oppose the Walsh resolution proposing the inquiry before the Senate interstate commerce committee, and that $7,500 was paid to Mr. Child for writing a book for the joint committee about the Boulder Dam project. • •

Producing an account book taken by the investigators from the files of the joint committee, Robert E. Healy, chief counsel for the commission, asked Mr. Grimshaw to identify payments noted in it. Mr. Grimshaw testified that $5,000 had been paid as an initial fee to Ernest Greenwood, a former newspaper man, for writing a book, "Aladdin U. S. A.," brought out by Harper's, and that J. Bart Campbell, a Washington newspaper man, was receiving $150 a month from the committee in payment for utility news gathered by him and sold to the joint committee. He did not act as a publicity agent.

George H. Francis of New York, auditor for the joint committee and the National Electric Light Association, testified that besides its yearly income of more than $1,000,000, the N.E.L.A. has handled a special fund for educational and research work to which the larger power companies contribute in addition to taking care of the deficiencies incurred by the association.

Mr. Grimshaw presented a table of total contributions of $1,000 or more by groups of utility companies to the Joint Committee of National Utility Associations. These numbered 26 in all, the ten largest contributors being: Insull companies, $61,750; Electric Bond & Share companies, $60,994; Byllesby companies, $36,992; Brady companies, $32,000; North American companies, $28,000; United Gas Improvement companies, $20,000; Columbia Gas & Electric, $20,000; Public Service Electric & Gas, $20,000; Doherty companies, $16,000; Stone & Webster companies, $16,000.

## Debate on Boulder Dam Bill Begins in Senate

Discussion of the Swing-Johnson Boulder Dam bill was beginning in the United States Senate on Thursday as the ELECTRICAL WORLD closed its forms. Prediction from Washington is that the measure will be before the Upper House for at least a week.

The House rules committee at a session on April 24 reached no decision in the matter of granting priority in the consideration of the Boulder Dam bill. Representative Smith of Idaho, chairman of the committee having jurisdiction, is requesting a rule to allow six hours of general debate to be divided equally between those favoring and those opposing the bill. In requesting priority ruling for the measure, Mr. Smith stated that, after considering the matter for six years, Congress should settle the controversy by enacting legislation authorizing construction, subject to ratification by six of the seven states involved. Chairman Snell of the rules committee pointed out that it ought to be possible to provide for flood control without going into power development.

Representative Taylor of Colorado stated the case for the upper basin states, bringing out that their chief concern is in preserving their water rights. "There are three ways of settling the question of allocation of water," he said—"first, for the states to come to an agreement among themselves; second, for the Supreme Court to decide the question as it did in a dispute between Colorado and Kansas over division of the water of the

Arkansas River, and, third, for Congress to adopt legislation making the allocation. Since the states will not agree nor accept a ruling from the Supreme Court, the only remaining way is to let Congress decide."

## Los Angeles "Times" Is for Flood Control First

Harry Chandler, publisher of the Los Angeles *Times*, speaking at a dinner tendered to him and other newspaper men in New York on Wednesday evening, told of the difficulties in the way of agreement on the Boulder Dam project on the Colorado for irrigation and power and predicted that some parts of the plan would have to be abandoned, at least temporarily, and agreement reached on a flood-control dam. Politics and mistaken opinions so surrounded the project contemplated in the Hoover compact that the seven states involved could not unite, he said; but all elements admitted the necessity of a dam to eliminate the always present threat of inundation in the Imperial Valley. If the dam were built with a wide enough base, developments for power might come later.

## Tacoma May Ask Bids for Second Cushman Unit

The city of Tacoma, Wash., contemplates letting contracts for construction of the second unit at its Cushman plant before the end of the year. The major contracts will be for a dam and a tunnel 2½ miles long to carry the water to where it will be dropped down through steel penstocks to the second power house.

In the first unit of the new Lake Cushman plant, completed early in 1926, the city is developing 50,000 hp., and at the sixteen-year-old La Grande plant on the Nisqually River it is developing 32,000 hp. In the second unit of the Cushman plant, the engineering survey for which is now under way, there will be developed 140,000 hp., according to the present plans of the city engineering department. It will also pave the way for the installation of 25,000 additional horsepower at the first Cushman power house, giving the city altogether a future total of 247,000 hp.

## Rural Electrification Project on National Scale

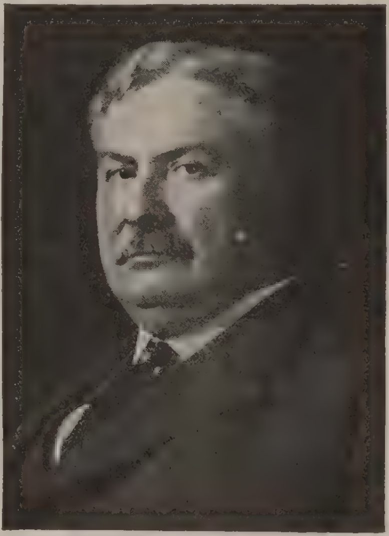
Under the auspices of the Committee on the Relation of Electricity to Agriculture, operating in conjunction with a Maryland state committee, a new experimental enterprise, to be known as the "national rural electric project," is soon to be established. It will be within easy driving distance of the national capital, probably adjacent to the highway between Washington and Baltimore. One of the first steps will be the erection on the grounds of the Agricultural College of the University of Maryland at College Park, on this national highway, of an exhibition building in which will be housed displays illustrative of the experiments being carried out on the national project and also on the various state experimental lines.

In some community not far from College Park six or eight farms, in a cluster if possible, will be selected as a base for the experiment. Dr. R. A. Pearson, president University of Maryland, heads the Maryland committee.

It is expected that it will take five years to obtain all the information desired. The National Electric Light Association, represented by Charles F. Stuart, chairman of its rural electric service committee, is participating.

## Death of James J. Wood

*Consulting Engineer at General Electric Company's Fort Wayne Works Since 1890—His Prominence in the Early Days of Arc Lighting*



JAMES J. WOOD, consulting engineer of the Fort Wayne works of the General Electric Company and one of the pioneers of electric lighting by arc lamps in America, died suddenly on April 19 at Asheville, N. C. He had just passed his seventy-second birthday and had gone to Asheville in an endeavor to recuperate from illness.

Mr. Wood was born at Kinsale, Ireland, being brought to America at the age of eight. The family lived in Connecticut for more than ten years. At the age of 18 he was graduated from the Brooklyn evening high school and in 1878 from the Brooklyn Polytechnic Institute. At that time the Brady Manufacturing Company, for which young Wood worked while pursuing his studies, was making castings and parts for electric dynamo machines invented by James B. Fuller of the Fuller Electric Company and by Hiram S. Maxim, then chief engineer of the United States Electric Lighting Company. As machine-shop foreman young Wood directed the construction of these machines and soon became interested in the electric lighting idea himself.

In 1879, after much private study and experimenting, he designed and built an arc-light dynamo of his own. This dynamo was so efficient that it caused the Fuller Electric Company to substitute Wood's machine for Fuller's and change the company name to the Fuller-Wood Company. After about ten years' service as electrical inventor for this and other companies in New York, Mr. Wood went to Fort Wayne in 1890, as the result of a commercial agreement with the old Thomson-Houston company, which then had a large interest in the contemporary Fort Wayne Electric Works. He had remained there ever since as the outstanding electrical engineer of the Fort Wayne plant.

When Mr. Wood went to Fort Wayne his dynamo and arc lamp were already in use extensively under the name of the "Wood arc-lighting system." He added accessory equipment to the system while at Fort Wayne, inventing types of meters and switch devices, as well as alternating-current dynamos and some of the earliest electric fans to be placed on the market. Before this he had been concerned in the manufacture of the Brayton oil engine installed in the first Holland submarine, and he built the first lamps for Hiram S. Maxim and the machines for constructing the main cables used on the original Brooklyn Bridge. His patents, numbering 240, included one for a dynamo for flood-lighting which was first used on the Statue of Liberty.

Mr. Wood was a fellow of the American Institute of Electrical Engineers and a member of the Quarter Century Club of the General Electric Company.

## Tokyo Congress Plans

*Many American Engineers Will Journey to Japan in October, 1929, to Take Part in World-Wide Conference of Technical Men*

A CABLEGRAM was received last Saturday by Maurice Holland, executive secretary of the American committee of the World Congress of Engineers to be held in Tokyo next year, from Baron C. Shiba, vice-president of the congress, outlining the plans and program. The meeting, Baron Shiba states, will convene in Tokyo on Oct. 30, 1929. The official languages of the congress will be English and Japanese. The first week will be devoted to technical papers and social meetings, the second week to inspection trips in Tokyo and vicinity, and the next fortnight to trips throughout Japan especially arranged to give the delegates an opportunity to visit the great industrial and engineering centers of the country.

The World Congress, which will be attended by engineers and scientists from all parts of the world, is designed to promote international co-operation in the study of engineering science and problems, and international authorities on engineering are being requested to prepare papers on subjects of interest and moment to engineers. Many notable technical men from America will attend the congress, eighty of the nation's foremost engineers and scientists having, as already reported, accepted membership on the American committee under the honorary chairmanship of Secretary Hoover and the active chairmanship of Dr. Elmer A. Sperry.

Dr. Sperry has made public the names of members of the various American committees charged with carrying out the plans for the undertaking. The chairmen are: Finance, John W. Lieb; technical program, Dugald C. Jackson; transportation, Frank B. Jewett; entertainment, O. C. Merrill; publicity, J. H. McGraw; promotion and attendance, George W. Fuller. These chairmen, with Gano Dunn, Maurice Holland, Charles F. Scott, Elmer A. Sperry, W. E. Wickenden and Calvin W. Rice, will make up an American executive committee under the chairmanship of Mr. Lieb.

## Purchases and Mergers

*Scattered Transactions of Comparatively Small Importance Compose the Week's Record — Tendency to Consolidate Subsidiaries Continues Manifest*

THE eleven companies which, as reported last week, are to be taken over by the Metropolitan Edison Company as part of the General Gas & Electric's plan to simplify the corporate structure of its subsidiaries are the Ortanna Electric Light & Power Company, the Boyertown Electric Company, the Annville & Palmyra Electric Light Company, the Bernville Light, Heat & Power Company, the Berks-Lehigh Power Company, the Birdsboro Electric Company, the Hamburg Gas & Electric Company, the Topton Electric Light & Power Company, the Weisenberg Township Electric Light & Power Company, the French Creek Electric Company and the Blue Mountain Electric Company.

The Harlem Valley Electric Corporation has filed a petition with the Public Service Commission of New York to acquire the franchises and plant of the Eastern New York Electric & Gas Company, which has its principal office in Mechanicville and distributes electricity in the villages of Brewster, Chatham, Pauling and Philmont and in many towns in Rensselaer, Columbia, Dutchess and Putnam Counties. Both companies are controlled by the Associated Gas & Electric Company.

Sale of the Rock River Valley Light & Power Company, a distribution system serving Barstow, Joslin and Hillsdale, Ill., to the People's Power Company of Moline awaits only approval of the Illinois Commerce Commission. The price was $30,000.

Sale of the electrical distribution system of the city of De Soto, Kan., to the Bonner Springs division of the Kansas Electric Power Company, Lawrence, has been agreed upon by the City Council. De Soto has heretofore purchased power wholesale from the Kansas Electric Power.

The municipal light, ice and water plants of Donalsonville, Ga., have been sold to the Georgia Power Company for $50,000.

The municipal electric plant at Vidalia, La., has been acquired by the Southwestern Gas & Electric Company.

Twenty per cent reduction in rates for Quincy (Calif.) electric consumers will result from the purchase of the Quincy Electric Light & Power Company by the Great Western Power Company of California.

Stockholders of the American Power & Light Company, meeting in Augusta, Me., on Tuesday, ratified the plan to exchange preferred stock for the common stock of the Montana Power Company. This makes the merger of the companies effective, as John D. Ryan and associates, who held control of Montana Power, have agreed to the two-to-one plan of exchange.

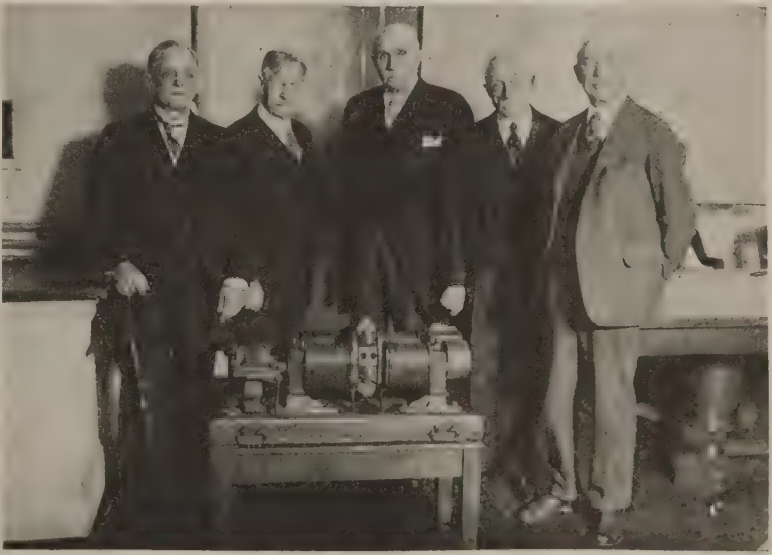
Reports from Chicago tell of a geographic readjustment of Insull-controlled companies by which the Middle West Utilities Company will have a majority interest in the National Electric Power Company and the Inland Power & Light Corporation, acquired last year from the Albert Emanuel and the A. E. Fitkin interests respectively. As a result of this transaction the New England Public Service Company, a Middle West Utilities subsidiary, has been transferred to the National Electric Power Company, which will be the holding company for all the properties of the system operating in the East, while the Kansas Electric Power Company, the Southwest Power Company and the Northwestern Public Service Company, former National Electric Power subsidiaries, have been transferred to direct control of the Middle West Utilities Company. The Inland Power & Light Corporation subsidiaries, operating in Kansas, Missouri, Arkansas, Texas and Michigan, are expected to be combined with the other Middle West Utilities properties on a geographic basis.

## I. W. Day Elected President of New England N.E.L.A.

Irvin W. Day, vice-president of the Connecticut Light & Power Company, Waterbury, Conn., was elected president of the New England Division of the National Electric Light Association at the annual meeting on Tuesday of this week at Boston. Other officers chosen were: Vice-president, C. H. Hodskinson, Boston Edison company; treasurer, F. L. Ball, Charles H. Tenney & Company, Boston; executive committee, George S. Williams of Maine, W. A. Buttrick of New Hampshire, W. C. Bell of Vermont, H. E. Duren of Massachusetts, David Daly of Rhode Island, A. D. Colvin of Connecticut and F. D. Gordon, ex officio. Section chairmen elected were: Accounting, J. W. Lester, Boston Edison company; Commercial, A. S. Moore, Brockton Edison company; Public Relations, Haller D. Seavey, Western Massachusetts Companies; Engineering, Frank R. Fowles, Portland, Me.

Following the election, Philip Cabot, professor of public utility management, Harvard Graduate School of Business Administration, gave an address upon the use of electricity in the home, predicting that this class of central-station business will ultimately become the most profitable of all. He predicted that within fifteen years comparatively little appliance business will be done by central stations in view of the progressive developments of other outlets.

## Five Electrical Pioneers Meet at Franklin Institute



*Thomson Sprague Brush Sperry Rice*

WORTHY of note was an assemblage at the Franklin Institute, Philadelphia, last week, when five men who have played distinguished parts in electrical history stood grouped around an ancient dynamo. They were Charles F. Brush, Elihu Thomson, Frank J. Sprague, Elmer A. Sperry and Edwin W. Rice, Jr. Dr. Brush, now 79, who made the dynamo, and Dr. Thomson, now 75, were the developers of rival arc-lighting systems in their early days, and each of the three younger men is old enough to have been an engineer of note when the art was in its infancy. Dr. Brush and Dr. Thomson were speakers at a meeting which followed the reunion.

## M. J. Insull Explains Situation on Colorado of Texas

Following an inspection of the properties of the Middle West Utilities Company in west Texas, Martin J. Insull of Chicago, head of the company and its several subsidiaries, made the statement at Abilene, Tex., last week that he may abandon the project of constructing a series of six dams and hydro-electric projects on the Colorado River, which would have involved an expenditure of approximately $25,000,000. The failure of the Brownwood Irrigation District to give the Insull interests an assurance that it will recognize priority rights of the Middle West Utilities Company on the 580,000 acre-feet of water of that stream which it proposed to use in the development of power was given as the reason for this possible change of plans.

"Unless we are given this assurance, we will not proceed with our project," Mr. Insull said. "I did not want to get mixed up in any dispute between any sections of the state, neither did I want to get into the hydro-electric power business in this state. I do not believe that it is a particularly profitable business. I would much rather buy the power from some one else at the dam than to build the dams. Lignite and oil will produce power today cheaper than water power on the Colorado River. When the Syndicate Power Company presented its plan for power on the Colorado River, we did not think that it was a particularly good business deal. We thought it was a good thing for Texas and that anything that was good for Texas was good for us. When our proposition failed to meet with approval of the West Texas Chamber of Commerce and when that body turned down our offer at Dallas, we got out of the Syndicate Power Company."

## Another Grandiose Scheme Proposed for Canada

Another ambitious plan for navigation and power has been put before the Canadian Parliament. Last year it was the Georgian Bay canal scheme, sponsored by the Sifton interests, which occupied the attention of the House through fourteen sittings. This year it is a bill to detail certain powers to the Great Lakes & Atlantic Canal & Power Company, which was incorporated 24 years ago, with general powers subject to the approval of the government. This company's proposal is to construct a 35-ft. waterway from tidewater to the Great Lakes at an outlay of approximately $200,000,000. In the process 2,800,000 hp. of electrical energy would be developed in the Province of Quebec, the promoters say.

Sponsors of the proposal think that it meets all the objections voiced in connection with St. Lawrence development. They declare that it will provide, without cost to the Dominion or provinces, an all-Canadian waterway, thereby relieving the country of financing and at the same time providing a route which Canada could control. The bill provides for a canal system from either Cornwall or Prescott to Lake St. Francis, and thence to Beauharnois and back to the St. Lawrence River in the neighborhood of Montreal.

The Great Lakes & Atlantic has notified the government of its willingness to complete the navigation works and turn them over to the government to operate without compensation, the power rights being sufficient inducement to proceed with the work.

# How Germany Solves Electric Problems

### Bin and Unit Pulverizers Both in Use in Central-Station Plants —High-Pressure Steam in Favor—Agricultural and Railroad Electrification—Statistics for 1927

By Dr. Gerhard Dehne*

Berlin, April 1, 1928.

A COMPLETE cessation of the building of power plants in Germany followed the war, but at the same time there arose a demand for electricity which made enlargements of existing installations imperative, and these had sometimes to be made hastily without waiting for the proper development of engineering ideas. Journeys to America were made by German engineers to study the new developments there, and some of these have now been applied to German plants with modifications and sometimes innovations that German conditions call for.

Most American plants burning pulverized coal use a central coal mill—the "bin system," as it is called in America—and some of the largest German plants—for example, the Klingenberg plant in Berlin—have adopted this method. Many private plants, however, have installed unit pulverizers, simplifying construction. This method was followed in the new plant of the communal Elektrizitätswerk Mark in Westphalia with such good results that it is likely to grow in use. Electrical filters to eliminate gas fumes have been employed by the Leunawerke with success.

In America boilers have long operated at a pressure of 84 to 100 atmospheres. In Germany the Grosskraftwerk Mannheim operates with a pressure of 100 atmospheres. In the Siemens-Schuckert cable works there was installed last year a Benson boiler at 230 atmospheres, which burns 30 tons of pulverized coal an hour, and boilers burning from 30 to 40 tons were installed in 1927 in many power houses without causing any difficulty.

The largest two-pole turbo-generator in Germany produces 40,000 kva. at 80 per cent power factor. The largest units with four poles (two-shaft machines)—those in the Klingenberg plant—have a capacity of 80,000 kw. each. The largest machines running at 3,000 r.p.m.—which are considerably cheaper than 1,500-r.p.m. machines—work very successfully in the Hamburg station, producing 37,500 kva., and preparations have been made to raise their rating to 50,000 kva. An experimental 44,000-kva. generator is already operating.

Some figures regarding the application of electricity to German agriculture were brought out in "Agricultural Week" in the Berlin exhibition halls recently. Use of electrical power increased from 1907 to 1925 by 3,000,000 hp., electric motors with a total rating of 3,334,051 hp. being in use in the last-named year. However, only 12.6 per cent of the farms are operated by electricity.

The electrification of the Breslau-Königszelt railroad in Silesia, completed in January, draws attention to a market for electrical energy which is becoming more important every year, that furnished by the German state railroads. Electrification began on a small scale before the war. Most of the work, however, has been accomplished in the last few years. Omitting the suburban districts of Berlin and Hamburg, there are three separate railroad systems—in central Germany (Leipzig-Magdeburg), in Bavaria around Munich and in Silesia (Breslau-Görlitz). In Bavaria the railway plants are operated by the water powers of the Alps, in Silesia by the less valuable pit coal and in central Germany by brown (soft) coal, which is coming into extensive employment. The whole length of the state lines, which include nine-tenths of all German railroads, was 33,306 miles in January, 1928. Of this, 760 miles were electrified, geographically divided as follows: Bavaria, 381; Silesia, 160; central Germany, 117; Berlin, 49; Baden, 30; Hamburg, 23. In 1928 the electrification of the Berlin urban and suburban railways, with a length of about 310 miles, will be finished.

According to reports by the "chambers of industry and commerce" and statements made by Dr. Carl Friedrich von Siemens at the annual meeting of the Siemens & Halske company, 1927 was in most branches of the German electrical industry a very satisfactory year. Seventy-five per cent of the electrical energy used in Germany is produced in plants owned or controlled by the nation, the states or the communes. These public utility undertakings have recently placed contracts for electrical equipment and supplies of various kinds.

---

*Dr. Dehne's first Berlin article appeared as a letter to the editor on March 24 (page 619).

# Electrical Engineers at Conowingo

*Inspection of Plant Follows Full Discussion of Its Features at Closing Sessions of Baltimore Regional Institute Meeting*

A TRIP to Conowingo participated in by 128 of the delegates to the regional meeting of the Middle Eastern District of the American Institute of Electrical Engineers, held in Baltimore, brought it to a successful close on Friday, April 20. The earlier sessions were reported in the ELECTRICAL WORLD last week. Those of Thursday were devoted to the design, transmission, communication and operating stability features of the Conowingo development. Following a general review of the economic factors which led to the erection of the power plant at this site, Alexander Wilson, 3d, outlined the construction methods utilized and the design of the hydraulic equipment.

The electrical features of the Conowingo plant and of the receiving stations in Philadelphia were reviewed by R. A. Hentz. These include a 220,000-volt substation built on the roof of the power plant, a 30,000-kva. synchronous condenser installed for stability purposes at Plymouth Meeting, and three-winding 220/69/13.3-kv. self-cooled transformer banks arranged for tap changing under load.

The 220-kv. transmission line between Conowingo and Plymouth Meeting was described by P. H. Chase. Two single-circuit tower lines, each with double-ground wire protection, are used. Conductors are of 795,000-circ. mil steel-reinforced aluminum. Slip clamps are used to decrease unbalanced longitudinal stresses on the towers in the event of conductor breakage.

In the discussion following the presentation of these papers F. G. Baum welcomed the introduction of 220-kv. lines in Eastern practice and mentioned the satisfactory service yielded by such construction for many years in West Coast work. R. L. Thomas called attention to the agreement with the Holtwood plant, further upstream, under which water is purchased with a net gain of from 84,000,000 kw.-hr. to 100,000,000 kw.-hr. yearly. P. L. Alger commented upon the use of rotors built up on the job, with heavy plates and riveted construction, and installed, consequently, without factory-shop tests.

The communication system for use in the plant in connection with the transmission line and in load dispatching was outlined in a paper by W. B. Beals and E. B. Tuttle. The value of co-operative consideration of such problems by utility and telephone company engineers was suggested as desirable at an early stage in the planning of the project.

A quantitative mechanical analysis of power-system transient disturbances as applied to the problems arising in the several interconnections involved in this three-company tie-in was detailed by R. C. Bergvall and P. H. Robinson in a paper read by the former. Records were obtained by taking motion pictures of an equivalent mechanical system.

The superexcitation of synchronous condensers for the Conowingo system, with particular attention to the design limits of the excitation equipment and the possible emergency condenser output, was treated by D. M. Jones.

In the ensuing discussion F. G. Baum pointed out the value of synchronous condensers in increasing the capacity of the line by taking care of the line-charging capacity, which at one time presented a difficult transmission-line problem. A. E. Bauhan said that with the three-company tie introduced by the present interconnection he anticipated an increased number of voltage dips and relatively unimportant disturbances, but that these would not, he felt, be of a serious nature in general. A. F. Bang questioned the desirability of mounting an outdoor switching structure on the roof of the generating station, as limiting future expansion and introducing oil-fire hazards, and expressed disapproval of the plan of placing reactances on the high-voltage side of transformers in transmission work while using them on the low-voltage side in cable distribution practice.

# Symposium at New Haven on Surge Measurements

In addition to the papers covering electric power on street railways and the electrification of steam railroads which, as listed in the ELECTRICAL WORLD for April 7 (page 726), will be presented when the regional meeting of the American Institute of Electrical Engineers meets at New Haven next month, there will be a symposium on surge measurements and protective devices. This will be held on the opening morning, Wednesday, May 9, and will include the following papers:

"Application of Relays for Protection of Power-System Interconnections," L. N. Crichton and H. C. Graves, Westinghouse Electric & Manufacturing Company.

"Application of Wound-Type Current Transformers to High-Voltage Circuit Breakers," J. C. Rea, Pacific Electric Manufacturing Company.

"Relation Between Transmission-Line and Transformer Insulation," W. W. Lewis, General Electric Company.

"Rationalization of Transmission-System Insulation Strength," Philip Sporn, American Gas & Electric Company.

"Hall High-Speed Recorder," C. I. Hall, General Electric Company.

"Pages from the Hall High-Speed Recorder," E. M. Tingley, Commonwealth Edison Company.

"Oscillograph Recording of Transmission-Line Disturbances," J. W. Legg, Westinghouse Electric & Manufacturing Company.

"High-Speed Graphic Voltmeter," A. F. Hamdi and H. D. Braley, New York Edison Company.

In the afternoon of Wednesday these papers are to be presented:

"Selection of Railway Motor Equipment by Principles of Similar Speed-Time Curves," B. A. Widell, General Electric Company.

"Shunting of Track Circuit in Polyphase Continuous Inductive Train Control," C. F. Estwick, General Railway Signal Company.

"The Diverter-Pole Generator," E. D. Smith, Jr., Rochester Electric Products Corporation.

"Electric Reduction in Hard Rubber, Pyrex, Glass, Fused and Crystalline Quartz," H. H. Race, Cornell University.

Another paper not previously noted will be given on Friday afternoon by L. A. Sheldon of the General Electric Company on the mercury boiler and turbine.

# Competition for Los Angeles Ornamental Lighting

The Affiliated Improvement Associations of Los Angeles, representing 130 organizations, are urging the City Council to authorize competitive bidding for furnishing energy and maintenance for the ornamental lighting systems in the city. This service is paid for by annual direct assessments on property owners on the streets on which there are ornamental lighting posts. The assessments total more than $1,000,000 a year and are increasing as additional systems are installed.

A practical monopoly on this business is held by the Municipal Bureau of Power and Light through its political connections with the Board of Public Works. The Power Bureau charges 4 cents a kilowatt-hour. The Los Angeles Gas & Electric Corporation has offered the same service for 3 cents a kilowatt-hour.

# Ferguson Against Federal Regulation of Utilities

Speaking on the utility question in its relation to politics, Samuel Ferguson, president of the Hartford (Conn.) Electric Light Company, declared Monday in an address before the national convention of the League of Women Voters at Chicago:

"I can raise no possible objection to being regulated by a fair-minded body, whether state or federal, provided that body could devote itself exclusively to regulating me according to local needs. But if in a rapidly changing industry rules and regulations necessary for my locality must also conform to the rules required by the vastly different conditions in California, Illinois or Maine, and be consistent all over the country, you can readily see that we shall be enmeshed in a hopeless snarl of red tape."

Congress can, by a very simple enactment, delegate its authority to the joint jurisdiction of the state utility commissions interested in particular interstate transactions, he said.

"One rather appealing fallacy," Mr. Ferguson observed in the course of his remarks, "has been indorsed by ex-Governor Pinchot and others, namely, that a fair return is one which will keep the company's securities at par, on the theory that this would be sufficient to make possible the obtaining of new capital when necessary for extensions. This is a policy of stagnation and high prices. If progress is to be rapid, capital must be anxious to be obtained and to be employed. To employ the maximum capital, growth must be as rapid as possible, and the only way to stimulate the maximum of growth is by a policy of minimum prices for the product sold."

Pointing out the fallacy of stressing fuel rather than distribution costs, indulged in by advocates of government operation at Muscle Shoals and Boulder Dam, Mr. Ferguson said that this undue prominence given to the smallest item of electrical costs distorted the picture.

## Stevenson Creek Arch Dam Undergoes Severe Tests

Although no additional engineering tests have been made so far this year upon the experimental concrete arch dam on Stevenson Creek, in the mountains near Fresno, Cal., the Bureau of Standards, which has co-operated with the Engineering Foundation's committee of investigation in this enterprise, reports that the dam has undergone severe tests occasioned by floods. A flood which destroyed all the observation platforms and caused the choking of the undersluice filled the reservoir with rock, sand and silt to an average depth of about 40 ft. at the upstream face of the dam. With this débris against the dam the water filled the reservoir and at times rose to a height of about 3 ft. above the crest. During the winter just past the reservoir has been full, and a small amount of water has been running over the top of the dam. The only observed effects produced by unexpected pressure of débris and water have been a slight extension of the cracks near the bottom of the dam which occurred during a previous load test, the formation of an additional crack near the bottom and a small increase in the deflection of the dam.

The test has yielded results which give direct information on the temperatures in the concrete and on strains, stresses and deflections in the dam. The results also afford a basis for comparison with the stresses and deflections as computed by current methods of design. There was reasonably good agreement with the computed stress at approximately the mid-height of the dam, but at the top the agreement was poor. Results of tests of a celluloid model of the dam at Princeton University agree so well with the results from the actual structure that added confidence is felt in the use of models in designing arch dams. The Bureau of Reclamation is building at the University of Colorado, Boulder, a concrete model of the Stevenson Creek Dam, which will be tested for comparison with the Stevenson Creek Dam; also a model of the Gibson Dam, which is to be built in Montana and which will be about 900 ft. long and 165 ft. high.

The Stevenson Creek Dam is now 60 ft. in height. The Engineering Foundation plans to carry it higher.

# Briefer News

Duke Power Company Builds Lines Into Marion, N. C.—The Duke Power Company has a large force of men working on a 100,000-volt power line that is being brought from its Bridgewater plant at Lake James into Marion, N. C., to furnish power for textile plants. Five acres of land just outside the city will be used for a substation, which is to be erected soon.

Wisconsin Utilities Association Elects Officers.—The annual election of officers for the Wisconsin Utilities Association, which is conducted by mail ballot, was held last week and resulted as follows: President, C. R. Phenicie, Green Bay, vice-president Wisconsin Public Service Corporation; vice-president, D. E. Callender, Racine; treasurer, Ewald Haase, Milwaukee; publicity director, M. H. Frank, Fond du Lac; assistant publicity director, E. J. Steinberg, Milwaukee.

Oregon Commission to Evaluate Portland Companies.—An order has been entered by the Oregon Public Service Commission for a rate-fixing valuation of all properties belonging to the Portland Electric Power Company and the Northwestern Electric Company, whose consolidation was forbidden at a recent special election. The commission thinks it probable that the present rates of the two companies are inconsistent with the rate base determined by the commission in 1916.

Kansas City Chamber of Commerce Starts Courses in Public Utility Economics.—Under the auspices of the Kansas City Chamber of Commerce an evening course in public utility economics is being given at the Kansas City School of Commerce. It began on April 16 and will last for eight weeks, under the direction of Charles H. English. Special lectures on various phases of public utility administration will be given by experienced utility men, engineers and others, among them L. A. Pettit, Missouri Power & Light Company; C. C. Smith, A. E. Bettis, H. H. Kuhn and F. S. Dewey, Kansas City Power & Light Company, and S. B. Irelan, Henry L. Doherty & Company.

Southwestern Public Service Association Meets in Dallas Next Week.—Increasing the domestic load, refrigeration, organizing for service to large power customers, safety methods, rural electrification and the selection and training of personnel are the topics selected for discussion at the Electric Section of the Southwestern Public Service Association, which will hold its thirty-third annual convention at Dallas from Wednesday to Saturday of next week. The Electric Section and the other sections will meet in the afternoons. The general sessions, in the mornings, will be addressed by executive heads of the national utility associations and other well-known men.

Decatur Rate Reduction Contingent on Increase in Number of Customers.—The Illinois Power & Light Corporation has submitted to the Decatur City Council a proposal to establish an 8-cent, 6-cent and 3-cent rate to supplant the present charge of 9, 7 and 4 cents upon condition that the company obtains 17,000 patrons in the city with an average householder consumption of 400 kw.-hr. annually. The new tariff will be effective July 1 if this condition is met.

Montreal's 66,000-Volt Underground Cables.—Before the Montreal branch of the Engineering Institute of Canada on April 20 H. Milliken, chief engineer of the Montreal Light, Heat & Power Consolidated, described the city's new 66,000-volt underground cables and the new 4,000-volt distribution substation in the heart of the city. The cables, which extend about 4,000 ft. from the company's Vallée station to a double overhead 66,000-volt ring around the city, are, as so far installed, six in number, single-conductor, comprising two three-phase circuits. A third circuit will be installed soon, and eventually the present cable system will be duplicated and joined to the second ovehead ring.

Gering Farm Project in Nebraska Still in Litigation. — The district court at Gering, Neb., has upheld the legality of the recent act of the Legislature permitting rural communities to form districts for the purpose of purchasing electricity from municipalities and has dismissed the injunction that held up a recently called election. Nonresident landowners who asked for the injunction gave notice of appeal to the Supreme Court, which may tie the matter up for a year.

Erie Lighting Company's New Turbine.—A report just printed on the new 15,000-kw. turbine of the Erie (Pa.) Lighting Company, which went into operation about the beginning of the year, says that it exceeds efficiency specifications. This turbine, of General Electric manufacture, is the first fourteen-stage unit of its capacity to be designed and built by that company. It has doubled the previous capacity of the Erie plant, which is now one of the largest and most important base-load stations in the Pennsylvania division of the Associated Gas & Electric System. An 11,000-volt transmission line connects this plant with the Piney hydro-electric development on the Clarion River, which in turn is connected to the Seward steam station near Johnstown and the Deep Creek hydro plant in western Maryland.

Virginia Electric & Power Company's Budget.—Line extensions and connections, substations, improvements to distribution system and miscellaneous electrical items scheduled for completion in 1928 will cost the Virginia Electric & Power Company $2,500,000 or more.

Among these coming improvements are a 4,750-kw. substation at Norfolk, ornamental street lighting for Portsmouth, new equipment in various stations and substations, and an extension of transmission lines in northeastern North Carolina, $629,000 being appropriated for the last-named purpose.

SOUTHEASTERN WATER AND LIGHT ASSOCIATION MEETS AT ATLANTA.—The eighth annual meeting of the Southeastern Water and Light Association was held at Atlanta last week, representatives of municipal lighting plants and water departments predominating among the attendants as usual. New officers were elected as follows: President, R. B. Sims, Spartanburg, S. C.; vice-presidents, H. A. Lily, Badin, N. C.; W. W. Hunter, Augusta, Ga.; J. B. Farmer, Murfreesboro, Tenn., and J. F. Pearson, Orangeburg, S. C.; secretary, F. W. Chapman, Camden, S. C.
